$P_{\text{inlet pump}} \geq 2\, P_{\text{sat, 15C}} = 2 \times 1.705 = 3.41$ kPa

Process:

Assume $\Delta KE \approx \varnothing$, $v \approx$ constant. =>

Bernoulli Eq.7.16:

$v\,\Delta P + g\,H = 0$ =>

$$1000\ \text{J/kJ} \times 0.001001\ \text{m}^3/\text{kg} \times (3.41 - 100)\ \text{kPa} + 9.80665\ \text{m/s}^2 \times H = 0$$

$$\Rightarrow \quad \mathbf{H = 9.86\ m}$$

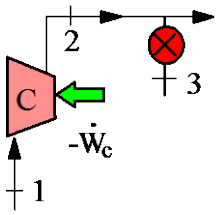
Since flow has some kinetic energy and there are losses in the pipe the height is overestimated. Also the start transient would generate a very low inlet pressure due to the necessary dynamic forces (it moves flow by suction).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.69

A pump/compressor pumps a substance from 150 kPa, 10°C to 1 MPa in a reversible adiabatic process. The exit pipe has a small crack, so that a small amount leaks to the atmosphere at 100 kPa. If the substance is (a) water, (b) R-134a, find the temperature after compression and the temperature of the leak flow as it enters the atmosphere neglecting kinetic energies.

Solution:



C.V.: Compressor, reversible adiabatic

Eq.4.13: $h_1 - w_c = h_2$; Eq.7.8: $s_1 = s_2$

State 2: P_2, $s_2 = s_1$

C.V.: Crack (Steady throttling process)

Eq.4.13: $h_3 = h_2$; Eq.7.8: $s_3 = s_2 + s_{gen}$

State 3: P_3, $h_3 = h_2$

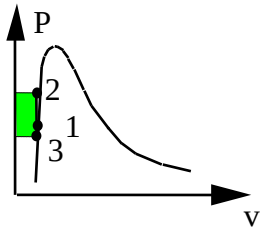
a) Water 1: compressed liquid, Table B.1.1

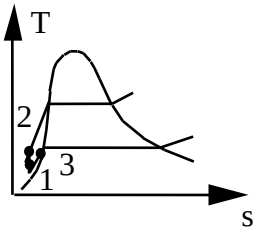
$$-w_c = + \int v dP = v_{f1}(P_2 - P_1) = 0.001 \text{ m}^3/\text{kg} \times (1000 - 150) \text{ kPa}$$

$$= 0.85 \text{ kJ/kg}$$

$h_2 = h_1 - w_c = 41.99 + 0.85 = 42.84$ kJ/kg => $\mathbf{T_2 = 10.2°C}$

P_3 , $h_3 = h_2$ $\Rightarrow$ compressed liquid at **~10.2°C**





States 1 and 3 are at 150, 100 kPa, and same v.

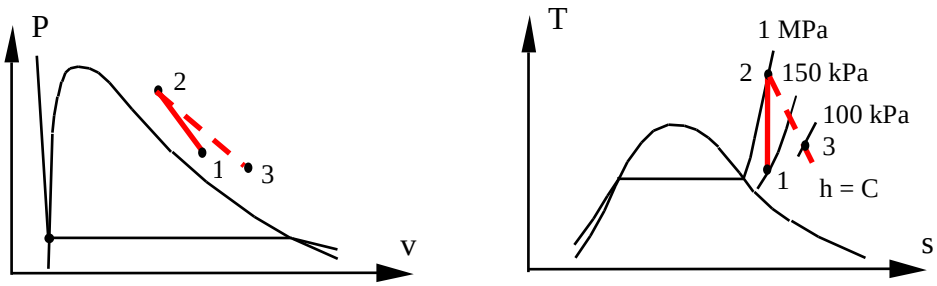
b) R-134a 1: superheated vapor, Table B.5.2, $s_1 = 1.8220$ kJ/kg-K

$s_2 = s_1$ & P_2 $\Rightarrow$ $\mathbf{T_2 = 83.1°C}$, $h_2 = 455.57$ kJ/kg

$-w_c = h_2 - h_1 = 455.57 - 410.60 = 44.97$ kJ/kg

P_3 , $h_3 = h_2$ $\Rightarrow$ $\mathbf{T_3 = 60.6°C}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*



7.70

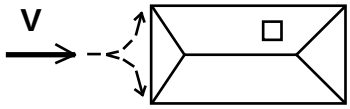
Atmospheric air at 100 kPa, 17°C blows at 60 km/h towards the side of a building. Assume the air is nearly incompressible find the pressure and the temperature at the stagnation point (zero velocity) on the wall.

Solution:

C.V. A stream line of flow from the freestream to the wall.

Eq.7.17:

$$v(P_e - P_i) + \frac{1}{2}(\mathbf{V}_e^2 - \mathbf{V}_i^2) + g(Z_e - Z_i) = 0$$



$$\mathbf{V}_i = 60 \frac{\text{km}}{\text{h}} \times 1000 \frac{\text{m}}{\text{km}} \times \frac{1}{3600} \frac{\text{h}}{\text{s}} = 16.667 \text{ m/s}$$

$$v = \frac{RT_i}{P_i} = \frac{0.287 \times 290.15}{100} \frac{\text{kJ/kg}}{\text{kPa}} = 0.8323 \frac{\text{m}^3}{\text{kg}}$$

$$\Delta P = \frac{1}{2v} \mathbf{V}_i^2 = \frac{16.667^2}{0.8323 \times 2000} \frac{(\text{m/s})^2}{\text{m}^3/\text{kg} \times \text{J/kJ}} = 0.17 \text{ kPa}$$

$$P_e = P_i + \Delta P = 100.17 \text{ kPa}$$

Then Eq.6.23 for an isentropic process:

$$T_e = T_i (P_e/P_i)^{0.286} = 290.15 \text{ K} \times 1.0005 = \mathbf{290.3 \text{ K}}$$

Very small effect due to low velocity and air is light (large specific volume)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.71

A small pump is driven by a 2 kW motor with liquid water at 150 kPa, 10°C entering. Find the maximum water flow rate you can get with an exit pressure of 1 MPa and negligible kinetic energies. The exit flow goes through a small hole in a spray nozzle out to the atmosphere at 100 kPa. Find the spray velocity.

Solution:

C.V. Pump. Liquid water is incompressible so work from Eq.7.15

$$\dot{W} = \dot{m}w = -\dot{m}v(P_e - P_i) \Rightarrow$$

$$\dot{m} = \dot{W}/ [-v(P_e - P_i)] = -2/[-0.001003 \text{ m}^3/\text{kg} (1000 – 150) \text{ kPa}]$$

$$= 2.35 \text{ kg/s}$$

C.V Nozzle. No work, no heat transfer, $v \approx$ constant => Bernoulli Eq.7.17

$$\frac{1}{2}\mathbf{V}_{ex}^2 = v\Delta P = 0.001 \text{ m}^3/\text{kg} (1000 – 100) \text{ kPa} = 0.9 \text{ kJ/kg} = 900 \text{ J/kg}$$

$$\mathbf{V}_{ex} = \sqrt{2 \times 900 \text{ J/kg}} = \mathbf{42.4 \text{ m/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.72

A speed boat has a small hole in the front of the drive with the propeller that sticks down into the water at a water depth of 0.25 m. Assume we have a stagnation point at that hole when the boat is sailing with 40 km/h, what is the total pressure there?

Solution:

C.V. A stream line of flow from the freestream to the wall.

Eq.7.17: $v(P_e - P_i) + \frac{1}{2}(\mathbf{V}_e^2 - \mathbf{V}_i^2) + g(Z_e - Z_i) = 0$

$$\mathbf{V}_i = 40 \frac{\text{km}}{\text{h}} \times 1000 \frac{\text{m}}{\text{km}} \times \frac{1}{3600} \frac{\text{h}}{\text{s}} = 11.111 \text{ m/s}$$

$$\Delta P = \frac{1}{2v} \mathbf{V}_i^2 = \frac{11.111^2}{0.001001 \times 2000} = 61.66 \text{ kPa}$$

$$P_i = P_o + gH/v = 101 + 9.81 \times 0.25/ (0.001001 \times 1000) = 103.45 \text{ kPa}$$

$$P_e = P_i + \Delta P = 103.45 + 61.66 = \mathbf{165 \text{ kPa}}$$

Remark: This is fast for a boat

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.73

You drive on the highway with 120 km/h on a day with 17°C, 100 kPa atmosphere. When you put your hand out of the window flat against the wind you feel the force from the air stagnating, i.e. it comes to relative zero velocity on your skin. Assume the air is nearly incompressible and find the air temperature and pressure right on your hand.

Solution:

Energy Eq.4.13: $\frac{1}{2}\mathbf{V}^2 + h_o = h_{st}$

$$T_{st} = T_o + \frac{1}{2}\mathbf{V}^2/C_p = 17 + \frac{1}{2}[(120\times1000)/3600]^2 \times (1/1004)$$

$$= 17 + 555.5/1004 = \mathbf{17.6°C}$$

$$v = RT_o/P_o = 0.287 \times 290/100 = 0.8323\ m^3/kg$$

From Bernoulli Eq.7.17:

$$v\Delta P = \frac{1}{2}\mathbf{V}^2$$

$$P_{st} = P_o + \frac{1}{2}\mathbf{V}^2/v = 100 + 555.5/(0.8323 \times 1000) = \mathbf{100.67\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.74

A small dam has a pipe carrying liquid water at 150 kPa, 20°C with a flow rate of 2000 kg/s in a 0.5 m diameter pipe. The pipe runs to the bottom of the dam 15 m lower into a turbine with pipe diameter 0.35 m. Assume no friction or heat transfer in the pipe and find the pressure of the turbine inlet. If the turbine exhausts to 100 kPa with negligible kinetic energy what is the rate of work?

Solution:

C.V. Pipe. Steady flow no work, no heat transfer.

States: compressed liquid B.1.1 $v_2 \approx v_1 \approx v_f = 0.001002\ m^3/kg$

Continuity Eq.4.3: $\dot{m} = \rho A\mathbf{V} = A\mathbf{V}/v$

$$\mathbf{V}_1 = \dot{m}v_1/A_1 = 2000\ kg/s \times 0.001002\ m^3/kg / (\tfrac{\pi}{4} 0.5^2\ m^2) = 10.2\ m\ s^{-1}$$

$$\mathbf{V}_2 = \dot{m}v_2/A_2 = 2000\ kg/s \times 0.001002\ m^3/kg / (\tfrac{\pi}{4} 0.35^2\ m^2) = 20.83\ m\ s^{-1}$$

From Bernoulli Eq.7.16 for the pipe (incompressible substance):

$$v(P_2 - P_1) + \tfrac{1}{2}(\mathbf{V}_2^2 - \mathbf{V}_1^2) + g(Z_2 - Z_1) = 0 \Rightarrow$$

$$P_2 = P_1 + [\tfrac{1}{2}(\mathbf{V}_1^2 - \mathbf{V}_2^2) + g(Z_1 - Z_2)]/v$$

$$= 150\ kPa + \frac{\frac{1}{2} \times (10.2^2 - 20.83^2) + 9.80665 \times 15}{1000 \times 0.001002} \frac{m^2 s^{-2}}{J/kJ \times m^3/kg}$$

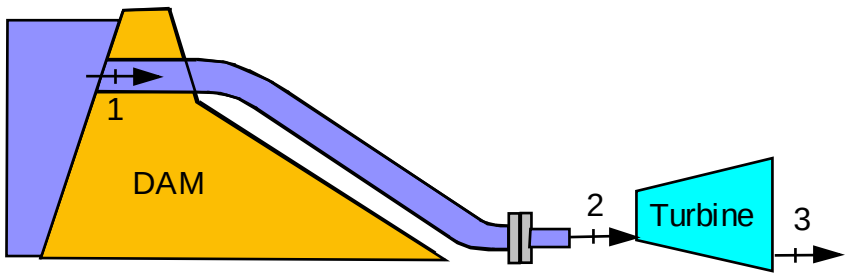
$$= 150 - 17.8 = \mathbf{132.2\ kPa}$$

Note that the pressure at the bottom should be higher due to the elevation difference but lower due to the acceleration. Now apply the energy equation Eq.7.13 for the total control volume

$$w = -\int v\, dP + \tfrac{1}{2}(\mathbf{V}_1^2 - \mathbf{V}_3^2) + g(Z_1 - Z_3)$$

$$= -0.001002\ (100 - 150) + [\tfrac{1}{2} \times 10.2^2 + 9.80665 \times 15] / 1000 = 0.25\ kJ/kg$$

$$\dot{W} = \dot{m}w = 2000\ kg/s \times 0.25\ kJ/kg = \mathbf{500\ kW}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.75

An air flow at 100 kPa, 290 K, 100 m/s is directed towards a wall. At the wall the flow stagnates (comes to zero velocity) without any heat transfer. Find the stagnation pressure a) assuming incompressible flow b) assume an adiabatic compression. Hint: T comes from the energy equation.

Solution:

Ideal gas: $v = RT_o/P_o = 0.287 \times 290/100 = 0.8323\ m^3/kg$

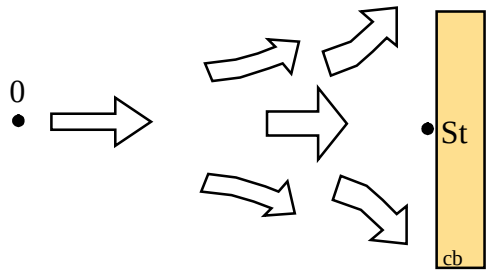
Kinetic energy: $\frac{1}{2}\mathbf{V}^2 = \frac{1}{2}(100^2/1000) = 5\ kJ/kg$

a) Reversible and incompressible gives Bernoulli Eq.7.17:

$$\Delta P = \frac{1}{2}\mathbf{V}^2/v = 5/0.8323$$

$$= 6\ kPa$$

$$P_{st} = P_o + \Delta P = 106\ kPa$$



b) adiabatic compression

Energy Eq.4.13: $\frac{1}{2}\mathbf{V}^2 + h_o = h_{st}$

$$h_{st} - h_o = \frac{1}{2}\mathbf{V}^2 = C_p\Delta T$$

$$\Delta T = \frac{1}{2}\mathbf{V}^2/C_p = 5/1.004 = 5°C$$

$$\Rightarrow\ T_{st} = 290 + 5 = 295\ K$$

Entropy Eq.7.9 assume also reversible process:

$$s_o + s_{gen} + \int (1/T)\, dq = s_{st}$$

as $dq = 0$ and $s_{gen} = 0$ then it follows that $s = constant$

This relation gives Eq.6.23:

$$P_{st} = P_o\left(\frac{T_{st}}{T_o}\right)^{\frac{k}{k-1}} = 100 \times (295/290)^{3.5} = \mathbf{106\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.76

A flow of air at 100 kPa, 300 K enters a device and goes through a polytropic process with n = 1.3 before it exits at 800 K. Find the exit pressure, the specific work and heat transfer using constant specific heats.

Solution:

C.V. Steady state device, single inlet and single exit flow.

Energy Eq.4.13: $h_1 + q = h_2 + w$ Neglect kinetic, potential energies

Entropy Eq.7.9: $s_1 + \int dq/T + s_{gen} = s_2$

$T_e = 800$ K; $T_i = 300$ K; $P_i = 100$ kPa

Process Eq.6.28: $P_e = P_i (T_e/ T_i)^{\frac{n}{n-1}} = 100\ (800/300)^{\frac{1.3}{0.3}} =$ **7 012 kPa**

and the process leads to Eq.7.18 for the work term

$$w = -\frac{n}{n-1} R (T_e - T_i) = -(1.3/0.3) \times 0.287 \text{ kJ/kg-K} \times (800 - 300) \text{ K}$$

$$= \mathbf{-\ 621.8\ kJ/kg}$$

$$q = h_e - h_i + w = C_P (T_e - T_i) + w$$

$$= 1.004 \text{ kJ/kg-K } (800 - 300) \text{ K} - 621.8 \text{ kJ/kg}$$

$$= \mathbf{-119.8\ kJ/kg}$$

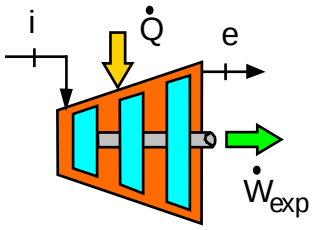
7.78

Helium gas enters a steady-flow expander at 800 kPa, 300°C, and exits at 120 kPa. The expansion process can be considered as a reversible polytropic process with exponent, n = 1.3. Calculate the mass flow rate for 150 kW power output from the expander.

Solution:



CV: expander, reversible polytropic process.
From Eq.6.28:

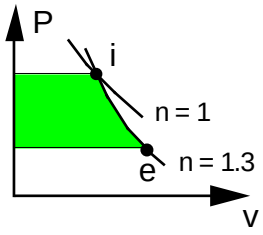
$$T_e = T_i \left(\frac{P_e}{P_i}\right)^{\frac{n-1}{n}} = 573.2 \left(\frac{120}{800}\right)^{\frac{0.3}{1.3}} = 370 \text{ K}$$

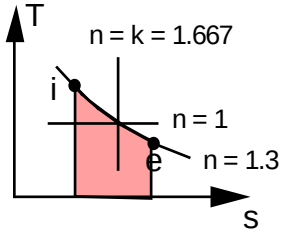
Work evaluated from Eq.7.18

$$w = -\int v dP = -\frac{nR}{n-1}(T_e - T_i) = \frac{-1.3 \times 2.07703}{0.3} \text{ kJ/kg-K } (370 - 573.2) \text{ K}$$

$$= 1828.9 \text{ kJ/kg}$$

$$\dot{m} = \dot{W}/w = 150 \text{ kW} / 1828.9 \text{ kJ/kg} = \mathbf{0.082\ kg/s}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.79

A flow of 4 kg/s ammonia goes through a device in a polytropic process with an inlet state of 150 kPa, -20°C and an exit state of 400 kPa, 60°C. Find the polytropic exponent n, the specific work and heat transfer.

Solution:

C.V. Steady state device, single inlet and single exit flow.

Energy Eq.4.13: $h_1 + q = h_2 + w$ Neglect kinetic, potential energies

Entropy Eq.7.9: $s_1 + \int dq/T + s_{gen} = s_2$

Process Eq.6.27: $P_1 v_1^n = P_2 v_2^n$:

State 1: Table B.2.2 $v_1 = 0.79774$, $s_1 = 5.7465$ kJ/kg K, $h_1 = 1422.9$ kJ/kg

State 2: Table B.2.2 $v_2 = 0.3955$, $s_2 = 5.8560$ kJ/kg K, $h_2 = 1590.4$ kJ/kg

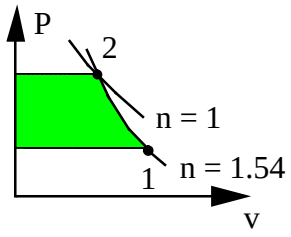
$$\ln (P_2/P_1) = n \ln (v_1/v_2) \quad => \quad 0.98083 = n \times 0.70163$$

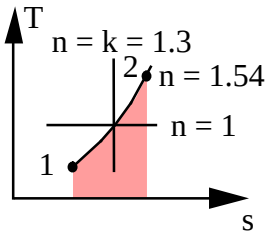
$$n = \ln (P_2/P_1) / \ln (v_1/v_2) = \mathbf{1.3979}$$

From the process and the integration of v dP gives Eq.7.18.

$$w_{shaft} = -\frac{n}{n-1}(P_2v_2 - P_1v_1) = -3.5132\,(158.2 - 119.66) = \mathbf{-135.4\ kJ/kg}$$

$$q = h_2 + w - h_1 = 1590.4 - 1422.9 - 135.4 = \mathbf{32.1\ kJ/kg}$$





Notice:
dP > 0
so dw <0

ds > 0
so dq > 0

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.80

Calculate the air temperature and pressure at the stagnation point right in front of a meteorite entering the atmosphere (-50 °C, 50 kPa) with a velocity of 2000 m/s. Do this assuming air is incompressible at the given state and repeat for air being a compressible substance going through an adiabatic compression.

Solution:

Kinetic energy: $\frac{1}{2}\mathbf{V}^2 = \frac{1}{2}(2000)^2/1000 = 2000$ kJ/kg

Ideal gas: $v_{atm} = RT/P = 0.287$ kJ/kg-K × 223 K/50 kPa = 1.28 m^3/kg

a) incompressible

Energy Eq.4.13: $\Delta h = \frac{1}{2}\mathbf{V}^2 = 2000$ kJ/kg

If A.5 $\Delta T = \Delta h/C_p = 1992$ K unreasonable, too high for that C_p

Use A.7: $h_{st} = h_o + \frac{1}{2}\mathbf{V}^2 = 223.22 + 2000 = 2223.3$ kJ/kg

$T_{st} = 1977$ K

Bernoulli (incompressible) Eq.7.17:

$\Delta P = P_{st} - P_o = \frac{1}{2}\mathbf{V}^2/v = 2000$ (m/s)^2/1.28 m^3/kg = 1562.5 kPa

$P_{st} = 1562.5 + 50 = 1612.5$ kPa

b) compressible

$T_{st} = 1977$ K the same energy equation.

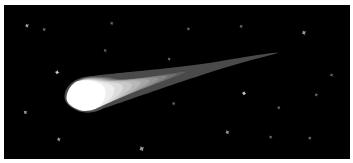
From A.7.1: $s^o_{T\,st} = 8.9517$ kJ/kg K; $s^o_{T\,o} = 6.5712$ kJ/kg K

Eq.6.19:

$$P_{st} = P_o \times e^{(s^o_{T\,st} - s^o_{T\,o})/R}$$

$$= 50 \times \exp\left[\frac{8.9517 - 6.5712}{0.287}\right]$$

$$= \mathbf{200\ 075\ kPa}$$



Notice that this is highly compressible, v is not constant.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.81

An expansion in a gas turbine can be approximated with a polytropic process with exponent n = 1.25. The inlet air is at 1200 K, 800 kPa and the exit pressure is 125 kPa with a mass flow rate of 0.75 kg/s. Find the turbine heat transfer and power output.

Solution:

C.V. Steady state device, single inlet and single exit flow.

Energy Eq.4.13: $h_i + q = h_e + w$ Neglect kinetic, potential energies

Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e$

Process Eq.6.28:

$$T_e = T_i (P_e/ P_i)^{\frac{n-1}{n}} = 1200\ (125/800)^{\frac{0.25}{1.25}} = 827.84\ \text{K}$$

so the exit enthalpy is from Table A.7.1

$$h_e = 822.2 + \frac{27.84}{50}(877.4 - 822.2) = 852.94\ \text{kJ/kg}$$

The process leads to Eq.7.18 for the work term

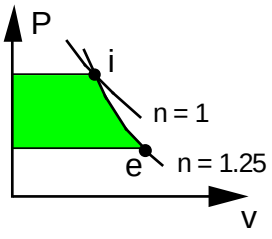
$$\dot{W} = \dot{m}w = -\dot{m}\frac{nR}{n-1}(T_e - T_i) = -0.75\ \frac{1.25 \times 0.287}{0.25} \times (827.84 - 1200)$$

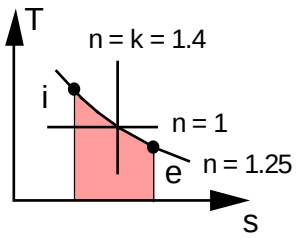
$$= \mathbf{400.5\ kW}$$

Energy equation gives

$$\dot{Q} = \dot{m}q = \dot{m}(h_e - h_i) + \dot{W} = 0.75(852.94 - 1277.81) + 400.5$$

$$= -318.65 + 400.5 = \mathbf{81.9\ kW}$$





Notice:
dP < 0
so dw > 0

ds > 0
so dq > 0

Notice this process has some heat transfer in during expansion which is unusual. The typical process would have n = 1.5 with a heat loss.

Steady state irreversible processes

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.82

Consider a steam turbine with inlet 2 MPa, 350^{o}C and an exhaust flow as saturated vapor 100 kPa. There is a heat loss of 6 kJ/kg to the ambient. Is the turbine possible?

Solution:

At the given states

Table B.1.3: $s_i = 6.9562$ kJ/kg K; $s_e = 7.3593$ kJ/kg K

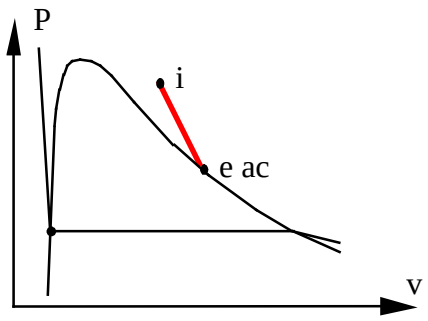
Do the second law for the turbine, Eq.7.8

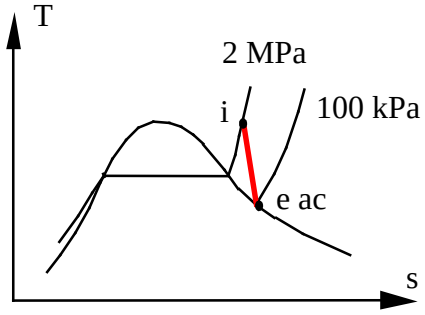
$$\dot{m}_e s_e = \dot{m}_i s_i + \int d\dot{Q}/T + \dot{S}_{gen}$$

$$s_e = s_i + \int dq/T + s_{gen}$$

$$s_{gen} = s_e - s_i - \int dq/T = 7.3593 - 6.9562 - 6/298 = 0.383 \text{ kJ/kgK} > 0$$

Entropy goes up even if q goes out. **This is an irreversible process**.





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.83

A large condenser in a steam power plant dumps 15 MW by condensing saturated water vapor at 45°C to saturated liquid. What is the water flow rate and the entropy generation rate with an ambient at 25°C?

Solution:

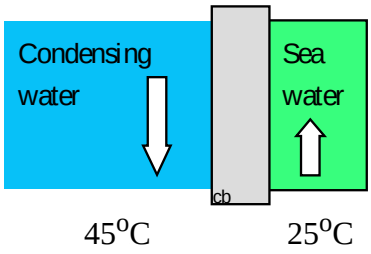
This process transfers heat over a finite temperature difference between the water inside the condenser and the outside ambient (cooling water from the sea, lake or river or atmospheric air)

C.V. The Condensing water flow

Energy Eq.: $0 = \dot{m}\,(h_g - h_f) - \dot{Q}_{out}$

$$\dot{m} = \dot{Q}_{out} / h_{fg} = \frac{15\ 000}{2394.77}\ \frac{kW}{kJ/kg} = \mathbf{6.264\ kg/s}$$

C.V. The wall that separates the inside 45°C water from the ambient at 25°C.



Entropy Eq. 7.1 for steady state operation:

$$\frac{dS}{dt} = 0 = \sum \frac{\dot{Q}}{T} + \dot{S}_{gen} = \frac{\dot{Q}}{T_{45}} - \frac{\dot{Q}}{T_{25}} + \dot{S}_{gen}$$

$$\dot{S}_{gen} = \frac{15}{25 + 273}\frac{MW}{K} - \frac{15}{45 + 273}\frac{MW}{K} = \mathbf{3.17}\ \frac{\mathbf{kW}}{\mathbf{K}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.84

R-410A at -5°C, 700 kPa is throttled so it becomes cold at –40°C. What is exit P and the specific entropy generation?

C.V. Throttle. Steady state,

Process with: $q = w = 0$; and $\mathbf{V}_i = \mathbf{V}_e$, $Z_i = Z_e$

Energy Eq.4.13: $h_i = h_e$,

Inlet state: Table B.4.1 $h_i = 50.22$ kJ/kg, $s_i = 0.1989$ kJ/kg-K

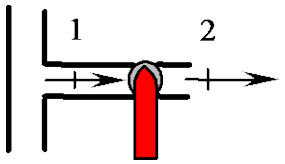
(slightly compressed liquid)

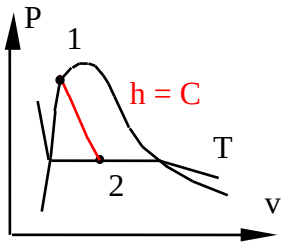
Exit state: Table B.4.1 since $h < h_g = 262.83$ kJ/kg it is two-phase

P = Psat = **175 kPa**

$$x_e = \frac{h_e - h_{f\,e}}{h_{fg\,e}} = \frac{50.22 - 0}{262.83} = 0.19107, \quad s_e = 0 + x_e\, 1.1273 = 0.2154 \text{ kJ/kg-K}$$

$s_{gen} = s_e - s_i = 0.2154 - 0.1989 =$ **0.0165 kJ/kg-K**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.85

Ammonia is throttled from 1.5 MPa, 35°C to a pressure of 291 kPa in a refrigerator system. Find the exit temperature and the specific entropy generation in this process.
The throttle process described in Example 6.5 is an irreversible process. Find the entropy generation per kg ammonia in the throttling process.

Solution:

The process is adiabatic and irreversible. The consideration with the energy given in the example resulted in a constant h and two-phase exit flow.

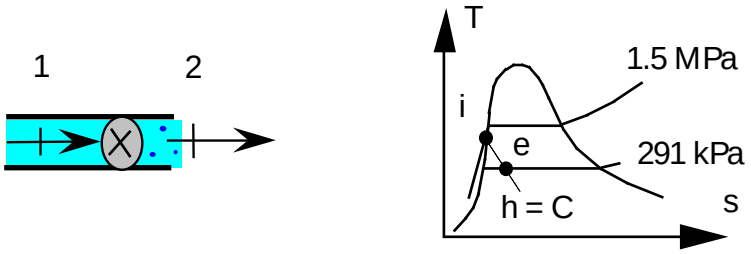
Table B.2.1: $s_i = 1.2792$ kJ/kg K, $h_i = 346.8$ kJ/kg

Table B.2.1: $x = (h_i - h_f)/h_{fg} = (346.8 - 134.41)/1296.4 = 0.1638$

$$s_e = s_f + x_e\, s_{fg} = 0.5408 + 0.1638 \times 4.9265 = 1.34776 \text{ kJ/kg K}$$

We assumed no heat transfer so the entropy equation Eq.7.9 gives

$$s_{gen} = s_e - s_i - \int dq/T = 1.34776 - 1.2792 - 0 = \mathbf{0.0686\ kJ/kg\ K}$$



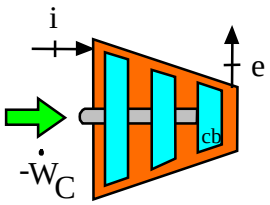
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.86

A compressor in a commercial refrigerator receives R-410A at -25°C and x = 1. The exit is at 1000 kPa and 20°C. Is this compressor possible?

Solution:

C.V. Compressor, steady state, single inlet and exit flow. For this device we also assume no heat transfer and $Z_i = Z_e$



From Table B.4.1 : $h_i = 269.77$ kJ/kg, $s_i = 1.0893$ kJ/kg-K

From Table B.4.2 : $h_e = 295.49$ kJ/kg, $s_e = 1.073$ kJ/kg-K

Entropy gives

$$s_{gen} = s_e - s_i - \int dq/T = 1.073 - 1.0893 - \int dq/T = \text{negative}$$

The result is negative unless dq is negative (it should go out, but T < T ambient) so this compressor is **impossible**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.87

R-134a at 30°C, 800 kPa is throttled in a steady flow to a lower pressure so it comes out at –10°C. What is the specific entropy generation?

Solution:

The process is adiabatic and irreversible. The consideration of the energy given in example 6.5 resulted in a constant h and two-phase exit flow.

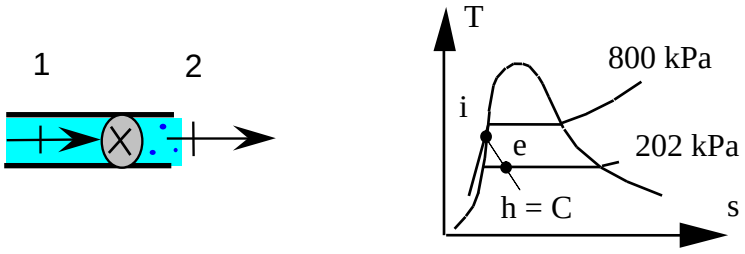
Table B.4.1: $h_i = 241.79$ kJ/kg, $s_i = 1.143$ kJ/kg-K (compressed liquid)

State 2: -10°C, $h_e = h_i < h_g$ so two-phase $x_e = (h_e - h_f)/h_{fg} = 0.267$

Table B.4.1: $s_e = s_f + x_e\, s_{fg} = 0.9507 + 0.267 \times 0.7812 = 1.16$ kJ/kg-K

We assumed no heat transfer so the entropy equation Eq.7.9 gives

$$s_{gen} = s_e - s_i - \int dq/T = 1.16 - 1.143 - 0 = \mathbf{0.017\ kJ/kg\ K}$$



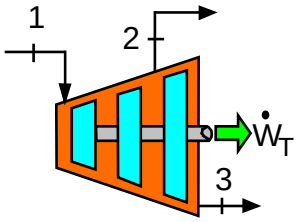
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.88

Analyze the steam turbine described in Problem 4.84. Is it possible?

Solution:

C.V. Turbine. Steady flow and adiabatic.



Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$;

Energy Eq.4.10: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3 + \dot{W}$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3$

States from Table B.1.3: $s_1 = 7.2337$, $s_2 = 7.3010$, $s_3 = 7.5066$ kJ/kg-K

$$\dot{S}_{gen} = 1 \times 7.301 + 4 \times 7.5066 - 5 \times 7.2337 = \mathbf{1.16\ kW/K} \quad > \mathbf{0}$$

Since it is positive => **possible.**

Notice the entropy is increasing through the turbine: $s_1 < s_2 < s_3$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.89

Two flowstreams of water, one at 0.6 MPa, saturated vapor, and the other at 0.6 MPa, 600°C, mix adiabatically in a steady flow process to produce a single flow out at 0.6 MPa, 400°C. Find the total entropy generation for this process.
Solution:

Continuity Eq.4.9: $\dot{m}_3 = \dot{m}_1 + \dot{m}_2$,

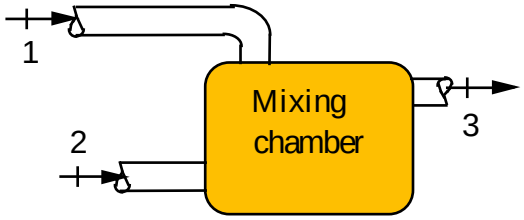
Energy Eq.4.10: $\dot{m}_3 h_3 = \dot{m}_1 h_1 + \dot{m}_2 h_2$

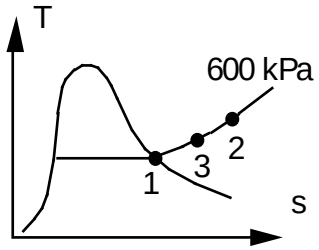
1: B.1.2 $h_1 = 2756.8$ kJ/kg, $s_1 = 6.760$ kJ/kg-K
2: B.1.3 $h_2 = 3700.9$ kJ/kg, $s_2 = 8.2674$ kJ/kg-K
3: B.1.3 $h_3 = 3270.3$ kJ/kg, $s_3 = 7.7078$ kJ/kg-K

$$\Rightarrow \quad \dot{m}_1/\dot{m}_3 = (h_3 - h_2) / (h_1 - h_2) = 0.456$$

Entropy Eq.7.7: $\dot{m}_3 s_3 = \dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen}$ =>

$$\dot{S}_{gen}/\dot{m}_3 = s_3 - (\dot{m}_1/\dot{m}_3)\, s_1 - (\dot{m}_2/\dot{m}_3)\, s_2$$
$$= 7.7078 - 0.456 \times 6.760 - 0.544 \times 8.2674 = \mathbf{0.128\ kJ/kg\ K}$$





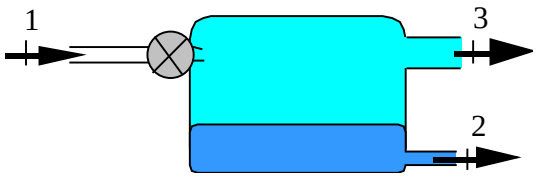
The mixing process generates entropy. The two inlet flows could have exchanged energy (they have different T) through some heat engines and produced work, the process failed to do that, thus irreversible.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.90

A geothermal supply of hot water at 500 kPa, 150°C is fed to an insulated flash evaporator at the rate of 1.5 kg/s. A stream of saturated liquid at 200 kPa is drained from the bottom of the chamber and a stream of saturated vapor at 200 kPa is drawn from the top and fed to a turbine. Find the rate of entropy generation in the flash evaporator.

Solution:



Two-phase out of the valve. The liquid drops to the bottom.

Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$

Energy Eq.4.10: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} + \int d\dot{Q}/T = \dot{m}_2 s_2 + \dot{m}_3 s_3$

Process: $\dot{Q} = 0$, irreversible (throttle)

B.1.1 $h_1 = 632.18$ kJ/kg, $s_1 = 1.8417$ kJ/kg-K

B.1.2 $h_3 = 2706.63$ kJ/kg, $s_3 = 7.1271$ kJ/kg-K,

$h_2 = 504.68$ kJ/kg, $s_2 = 1.53$ kJ/kg-K

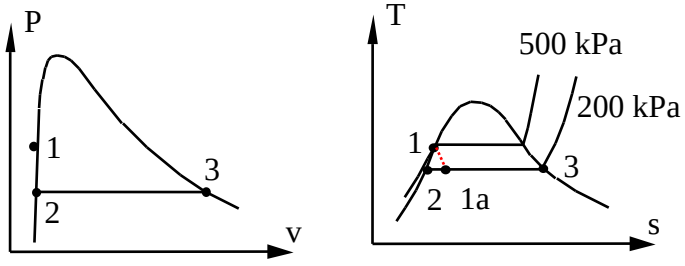
From the energy equation we solve for the flow rate

$$\dot{m}_3 = \dot{m}_1(h_1 - h_2)/(h_3 - h_2) = 1.5 \times 0.0579 = 0.08685 \text{ kg/s}$$

Continuity equation gives: $\dot{m}_2 = \dot{m}_1 - \dot{m}_2 = 1.41315$ kg/s

Entropy equation now leads to

$$\dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_1 s_1$$
$$= 1.41315 \times 1.53 + 0.08685 \times 7.127 - 1.5 \times 1.8417$$
$$= \mathbf{0.01855\ kW/K}$$



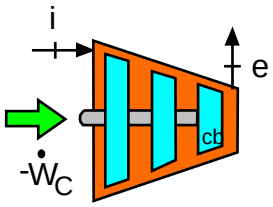
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.91

A compressor in a commercial refrigerator receives R-410A at -25°C and x = 1. The exit is at 2000 kPa and 80°C. Neglect kinetic energies and find the specific entropy generation.

Solution:

C.V. Compressor, steady state, single inlet and exit flow. For this device we also assume no heat transfer q = 0 and $Z_1 = Z_2$



Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e = s_i + 0 + s_{gen}$

From Table B.4.1 : $s_i = 1.0893$ kJ/kgK

From Table B.4.2 : $s_e = 1.1537$ kJ/kgK

Entropy generation becomes

$$s_{gen} = s_e - s_i = 1.1537 - 1.0893 = \mathbf{0.0644\ kJ/kgK}$$

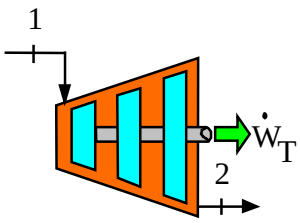
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.92

A steam turbine has an inlet of 2 kg/s water at 1000 kPa and 400°C with velocity of 15 m/s. The exit is at 100 kPa, 150°C and very low velocity. Find the power produced and the rate of entropy generation.

Solution:

C.V. Turbine. Steady flow and adiabatic.



Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2$;

Energy Eq.4.10: $\dot{m}_1(h_1 + \frac{1}{2}\mathbf{V}^2) = \dot{m}_2 h_2 + \dot{W}$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2$

States from Table B.1.3: $h_1 = 3263.88$ kJ/kg, $s_1 = 7.4650$ kJ/kgK,

$h_2 = 2776.38$ kJ/kg, $s_2 = 7.6133$ kJ/kgK

$$\dot{W} = \dot{m}_1(h_1 + \tfrac{1}{2}\mathbf{V}^2 - h_2) = 2 \text{ kg/s } (3263.88 + \tfrac{1}{2}\frac{15^2}{1000} - 2776.38) \text{ kJ/kg}$$

$$= \mathbf{975\ kW}$$

$$\dot{S}_{gen} = \dot{m}_1(s_2 - s_1) = 2 \text{ kg/s } (7.6133 - 7.4650) \text{ kJ/kgK} = \mathbf{0.3\ kW/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.93

A factory generates compressed air from ambient 100 kPa, 17^{o}C, by compression to 1000 kPa, 600 K after which it cools in a constant pressure cooler to 300 K by heat transfer to the ambient. Find the specific entropy generation in the compressor and in the cooler.

Solution
C.V. air compressor $q = 0$

Continuity Eq.: $\dot{m}_2 = \dot{m}_1$; Energy Eq.4.13: $0 = h_1 + w_{C\ in} - h_2$

Entropy Eq.: $0 = s_1 - s_2 + s_{gen\ comp}$

Table A.7 State 1: $h_1 = 290.19$ kJ/kg, $s^o_{T1} = 6.83521$ kJ/kg-K,

Table A.7 State 2: $h_2 = 607.32$ kJ/kg, $s^o_{T2} = 7.57638$ kJ/kg-K,

Table A.7 State 3: $h_3 = 300.47$ kJ/kg, $s^o_{T3} = 6.86926$ kJ/kg-K,

$$s_{gen\ comp} = s_2 - s_1 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1)$$

$$= 7.57638 - 6.83521 - 0.287 \ln(1000/100) = \mathbf{0.080\ kJ/kgK}$$

C.V. cooler $w = 0$

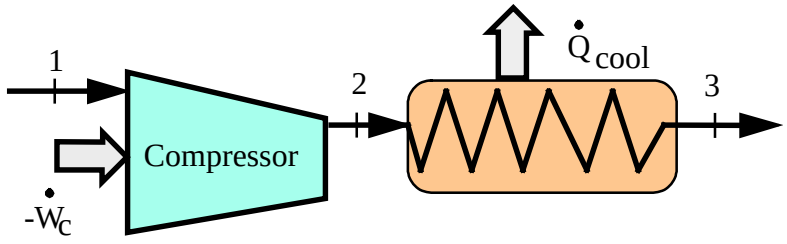
Continuity Eq.: $\dot{m}_3 = \dot{m}_1$; Energy Eq.4.13: $0 = h_2 - q_{out} - h_3$

Entropy Eq.: $0 = s_2 - s_3 - q_{out}/T_{amb} + s_{gen\ cool}$

$$q_{out} = h_2 - h_3 = 607.32 - 300.47 = 306.85\ \text{kJ/kg}$$

$$s_{gen\ cool} = s_3 - s_2 + q_{out}/T_{amb} = s^o_{T3} - s^o_{T2} + q_{out}/T_{amb}$$

$$= 6.86926 - 7.57638 + \frac{306.85}{290} = \mathbf{0.351\ kJ/kg}$$



Compressor section Cooler section

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.94

A mixing chamber receives 5 kg/min ammonia as saturated liquid at –20°C from one line and ammonia at 40°C, 250 kPa from another line through a valve. The chamber also receives 325 kJ/min energy as heat transferred from a 40°C reservoir. This should produce saturated ammonia vapor at –20°C in the exit line. What is the mass flow rate in the second line and what is the total entropy generation in the process?

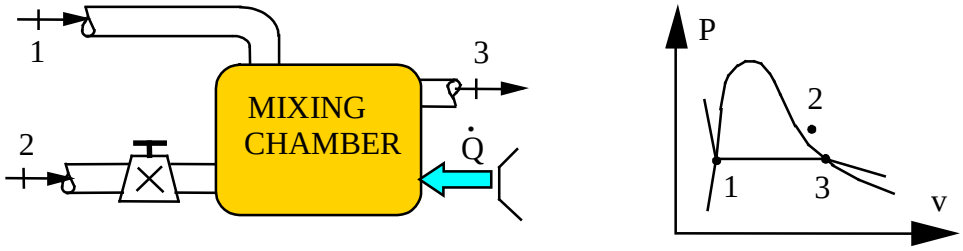
Solution:

CV: Mixing chamber out to reservoir

Continuity Eq.4.9: $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$

Energy Eq.4.10: $\dot{m}_1 h_1 + \dot{m}_2 h_2 + \dot{Q} = \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{Q}/T_{res} + \dot{S}_{gen} = \dot{m}_3 s_3$



From Table B.2.1: $h_1 = 89.05$ kJ/kg, $s_1 = 0.3657$ kJ/kg-K
From Table B.2.2: $h_2 = 1551.7$ kJ/kg, $s_2 = 5.9599$ kJ/kg-K
From Table B.2.1: $h_3 = 1418.05$ kJ/kg, $s_3 = 5.6158$ kJ/kg-K

From the energy equation:

$$\dot{m}_2 = [(\dot{m}_1(h_1 - h_3) + \dot{Q}]/(h_3 - h_2)$$

$$= [5 \times (89.05 - 1418.05) + 325] / (1418.05 - 1551.7)$$

$$= \mathbf{47.288\ kg/min} \Rightarrow \dot{m}_3 = 52.288 \text{ kg/min}$$

$$\dot{S}_{gen} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2 - \dot{Q}/T_{res}$$

$$= 52.288 \times 5.6158 - 5 \times 0.3657 - 47.288 \times 5.9599 - 325/313.15$$

$$= \mathbf{8.94\ kJ/K\ min}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.95

Carbon dioxide at 300 K, 200 kPa is brought through a steady device where it is heated to 600 K by a 700 K reservoir in a constant pressure process. Find the specific work, specific heat transfer and specific entropy generation.

Solution:

C.V. Heater and walls out to the source. Steady single inlet and exit flows.

Since the pressure is constant and there are no changes in kinetic or potential energy between the inlet and exit flows the work is zero. **w = 0**

Continuity Eq.4.11: $\dot{m}_i = \dot{m}_e = \dot{m}$

Energy Eq.4.13: $h_i + q = h_e$

Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e = s_i + q/T_{source} + s_{gen}$

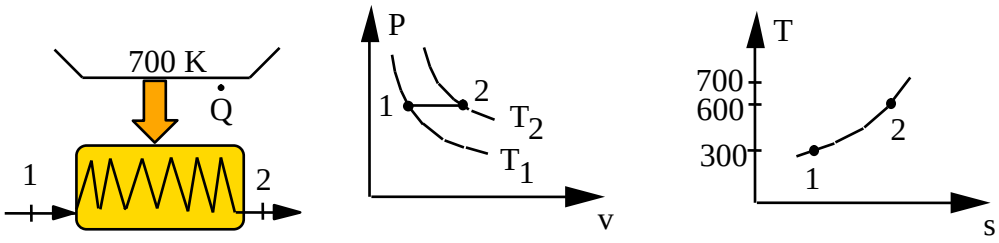
Properties are from Table A.8 so the energy equation gives

$q = h_e - h_i = 506.07 - 214.38 =$ **291.7 kJ/kg**

From the entropy equation

$s_{gen} = s_e - s_i - q/T_{source} = (5.5279 - 4.8631)$ kJ/kgK - 291.7 kJ/kg /700 K

$= 0.6648 - 0.4167 =$ **0.248 kJ/kg K**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.96

Methane at 1 MPa, 300 K is throttled through a valve to 100 kPa. Assume no change in the kinetic energy and ideal gas behavior. What is the specific entropy generation?

Continuity Eq.4.11: $\dot{m}_i = \dot{m}_e = \dot{m}$

Energy Eq.4.13: $h_i + 0 = h_e$

Entropy Eq.7.8, 7.9: $s_i + \int dq/T + s_{gen} = s_e = s_i + 0 + s_{gen}$

Properties are from Table B.7.2 so the energy equation gives

$h_e = h_i = 618.76$ kJ/kg => $T_e = 296$ K, $s_e = 11.5979$ kJ/kg-K

$s_{gen} = s_e - s_i = 11.5979 - 10.4138 =$ **1.184 kJ/kgK**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.97

A heat exchanger that follows a compressor receives 0.1 kg/s air at 1000 kPa, 500 K and cools it in a constant pressure process to 320 K. The heat is absorbed by ambient ait at 300 K. Find the total rate of entropy generation.

Solution:

C.V. Heat exchanger to ambient, steady constant pressure so no work.

Energy Eq.4.12: $\dot{m}h_i = \dot{m}h_e + \dot{Q}_{out}$

Entropy Eq.7.7: $\dot{m}s_i + \dot{S}_{gen} = \dot{m}s_e + \dot{Q}_{out}/T$

Using Table A.5 and Eq.8.25 for change in s

$$\dot{Q}_{out} = \dot{m}(h_i - h_e) = \dot{m}C_{Po}(T_i - T_e) = 0.1 \times 1.004(500 - 320) = 18.07 \text{ kW}$$

$$\dot{S}_{gen} = \dot{m}(s_e - s_i) + \dot{Q}_{out}/T = \dot{m}C_{Po} \ln(T_e/T_i) + \dot{Q}_{out}/T$$

$$= 0.1 \text{ kg/s} \times 1.004 \text{ kJ/kg-K} \ln(320/500) + 18.07 \text{ kW}/300 \text{ K}$$

$$= \mathbf{0.0154 \text{ kW/K}}$$

Using Table A.7.1 and Eq. 6.19 for change in entropy

$h_{500} = 503.36$ kJ/kg, $h_{320} = 320.58$ kJ/kg;

$s_{T_{500}} = 7.38692$ kJ/kg K, $s_{T_{320}} = 6.93413$ kJ/kg K

$$\dot{Q}_{out} = \dot{m}(h_i - h_e) = 0.1 \text{ kg/s } (503.36 - 320.58) \text{ kJ/kg} = 18.19 \text{ kW}$$

$$\dot{S}_{gen} = \dot{m}(s_e - s_i) + \dot{Q}_{out}/T$$

$$= 0.1 \text{ kg/s } (6.93413 - 7.38692) \text{ kJ/kg-K} + 18.19 \text{ kW}/300 \text{ K}$$

$$= \mathbf{0.0156 \text{ kW/K}}$$

7.98

A dual fluid heat exchanger has 5 kg/s water enter at 40°C, 150 kPa and leaving at 10°C, 150 kPa. The other fluid is glycol coming in at -10°C, 160 kPa and leaves at 10°C, 160 kPa. Find the mass flow rate of glycol and the rate of entropy generation.

Continuity Eqs.: Each line has a constant flow rate through it.

Energy Eq.4.10: $\dot{m}_{H_2O}\, h_1 + \dot{m}_{glycol}\, h_3 = \dot{m}_{H_2O}\, h_2 + \dot{m}_{glycol}\, h_4$

Entropy Eq.7.7: $0 = \dot{m}_{H_2O}\, s_1 + \dot{m}_{glycol}\, s_3 - \dot{m}_{H_2O}\, s_2 - \dot{m}_{glycol}\, s_4 + \dot{S}_{gen}$

Process: Each line has a constant pressure.

Table B.1: $h_1 = 167.54$ kJ/kg, $h_2 = 41.99$ kJ/kg, $s_1 = 0.5724$, $s_2 = 0.151$ kJ/kg-K

We could have used specific heat for the changes.

Table A.4: $C_{P\,gly} = 2.42$ kJ/kg-K so

$$h_4 - h_3 = C_{P\,gly}(T_4 - T_3) = 2.42\,[10 - (-10)] = 48.4 \text{ kJ/kg}$$

$$s_4 - s_3 = C_{P\,gly} \ln (T_4/T_3) = 2.42 \ln(283.15/263.15) = 0.1773 \text{ kJ/kgK}$$

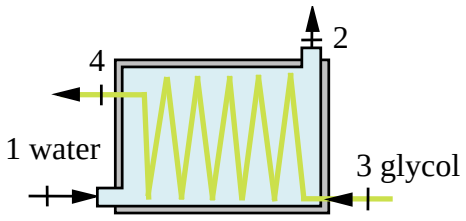
$$\dot{m}_{glycol} = \dot{m}_{H_2O} \frac{h_1 - h_2}{h_4 - h_3} = 5 \frac{167.54 - 41.99}{48.4} = \mathbf{12.97\ kg/s}$$

$$\dot{S}_{gen} = \dot{m}_{H_2O}(s_2 - s_1) + \dot{m}_{glycol}(s_4 - s_3)$$

$$= 5 \text{ kg/s } (0.151 - 0.5724) \text{ kJ/kgK} + 12.97 \text{ kg/s} \times 0.1773 \text{ kJ/kgK}$$

$$= \mathbf{0.193\ kW/K}$$

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for glycol and water each. The two flows exchange energy with no heat transfer to/from the outside.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

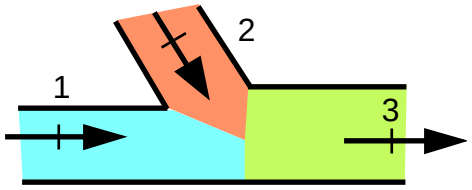
7.99

Two flows of air both at 200 kPa; one has 2 kg/s at 400 K and the other has 1 kg/s at 290 K. The two flows are mixed together in an insulated box to produce a single exit flow at 200 kPa. Find the exit temperature and the total rate of entropy generation.

Solution:

Continuity Eq.4.9:

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3 = 2 + 1 = 3 \text{ kg/s}$$



Energy Eq.4.10:

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen} = \dot{m}_3 s_3$

Using constant specific heats from A.5 and Eq.6.16 for s change.

Divide the energy equation with $\dot{m}_3 C_{Po}$

$$T_3 = (\dot{m}_1/\dot{m}_3)T_1 + (\dot{m}_2/\dot{m}_3)T_2 = \frac{2}{3} \times 400 + \frac{1}{3} \times 290 = \mathbf{363.33\ K}$$

$$\dot{S}_{gen} = \dot{m}_1(s_3 - s_1) + \dot{m}_2(s_3 - s_2)$$

$$= [1 \times 1.004 \ln (\frac{363.33}{400}) + 2 \times 1.004 \ln (\frac{363.33}{290})] \text{ kg/s} \times \text{kJ/kg-K}$$

$$= \mathbf{0.356\ kW/K}$$

Using A.7.1 and Eq.6.19 for change in s.

$$h_3 = (\dot{m}_1/\dot{m}_3)h_1 + (\dot{m}_2/\dot{m}_3)h_2 = \frac{2}{3} \times 401.3 + \frac{1}{3} \times 290.43 = 364.34 \text{ kJ/kg}$$

From A.7.1: $T_3 = \mathbf{364.44\ K}$ $\quad s_{T_3} = 7.06216$ kJ/kg K

$$\dot{S}_{gen} = [2\ (7.06216 - 7.15926) + 1\ (7.06216 - 6.83521)] \text{ kg/s} \times \text{kJ/kgK}$$

$$= \mathbf{0.03275\ kW/K}$$

The pressure correction part of the entropy terms cancel out as all three states have the same pressure.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.100

A condenser in a power plant receives 5 kg/s steam at 15 kPa, quality 90% and rejects the heat to cooling water with an average temperature of 17°C. Find the power given to the cooling water in this constant pressure process and the total rate of enropy generation when condenser exit is saturated liquid.

Solution:

C.V. Condenser. Steady state with no shaft work term.

Energy Eq.4.12: $\dot{m}\, h_i + \dot{Q} = \dot{m} h_e$

Entropy Eq.7.8: $\dot{m}\, s_i + \dot{Q}/T + \dot{S}_{gen} = \dot{m}\, s_e$

Properties are from Table B.1.2

$h_i = 225.91 + 0.9 \times 2373.14 = 2361.74$ kJ/kg , $h_e = 225.91$ kJ/kg

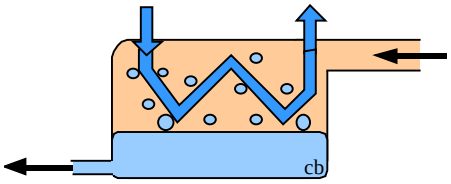
$s_i = 0.7548 + 0.9 \times 7.2536 = 7.283$ kJ/kg K, $s_e = 0.7548$ kJ/kg-K

$\dot{Q}_{out} = -\dot{Q} = \dot{m}\,(h_i - h_e) = 5(2361.74 - 225.91) =$ **10679 kW**

$\dot{S}_{gen} = \dot{m}\,(s_e - s_i) + \dot{Q}_{out}/T$

$= 5(0.7548 - 7.283) + 10679/(273 + 17)$

$= -32.641 + 36.824 =$ **4.183 kW/K**



Often the cooling media flows inside a long pipe carrying the energy away.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.101

A large supply line has a steady flow of R-410A at 1000 kPa, 60°C. It is used in three different adiabatic devices shown in Fig. P7.101, a throttle flow, an ideal nozzle and an ideal turbine. All the exit flows are at 300 kPa. Find the exit temperature and specific entropy generation for each device and the exit velocity of the nozzle.

Inlet state: B.4.2: $h_i = 335.75$ kJ/kg , $s_i = 1.2019$ kJ/kg-K

C.V. Throttle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e$ ($Z_i = Z_e$ and **V**'s are small)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + s_{gen}$

Exit state: $h_e = h_i = 335.75$ kJ/kg, $T_e =$ **47.9°C,** $s_e = 1.332$ kJ/kg-K

$s_{gen} = s_e - s_i = 1.332 - 1.2019 =$ **0.2 kJ/kg K**

C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2$ ($Z_i = Z_e$)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

The isentropic process ($s_e = s_i$) gives from B.4.2

$$\mathbf{T_e = 4.6^oC}, \quad \mathbf{s_{gen} = 0}, \quad h_e = 296.775 \text{ kJ/kg}$$

The energy equation becomes

$$\mathbf{V}_e^2/2 = h_i - h_e = 335.75 - 296.775 = 38.975 \text{ kJ/kg}$$

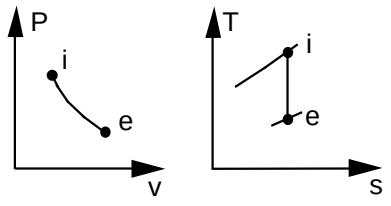
$$\mathbf{V}_e = \sqrt{2 \times 38.975 \times 1000} = \mathbf{279.2 \text{ m/s}}$$

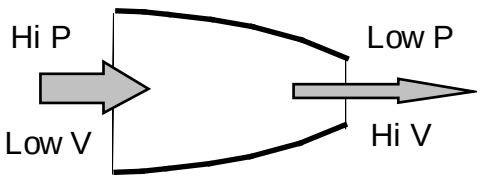
Turbine:

Process: Reversible and adiabatic => same as for nozzle except w, $\mathbf{V}_e = 0$

Energy Eq.4.13: $h_i = h_e + w$ ($Z_i = Z_e$)

$$\mathbf{T_e = 4.6^oC}, \quad \mathbf{s_{gen} = 0}, \quad h_e = 296.775 \text{ kJ/kg}$$



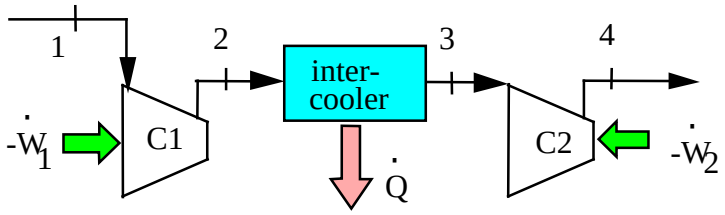


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.102

A two-stage compressor takes nitrogen in at 20°C, 150 kPa compresses it to 600 kPa, 450 K then it flows through an intercooler where it cools to 320 K and the second stage compresses it to 3000 kPa, 530 K. Find the specific entropy generation in each of the two compressor stages.

The setup is like this:



C.V.: Stage 1 nitrogen, Steady flow

Process: adibatic: $q = 0$, $s_{gen} = 0$

Energy Eq. 4.13: $-w_{C1} = h_2 - h_1$, Entropy Eq. 7.10: $0 = s_1 - s_2 + s_{gen\ C1}$

Assume constant $C_{P0} = 1.042$ from A.5 and Eq.6.16 for change in entropy

$$s_{gen\ C1} = s_2 - s_1 = C_{P0} \ln(T_2/T_1) - R \ln (P_2/P_1)$$
$$= 1.042 \ln(450/293.15) - 0.2968 \ln(600/150)$$
$$= \mathbf{0.0351\ kJ/kgK}$$

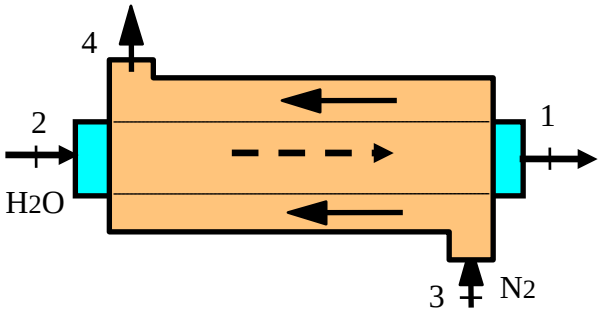
$$s_{gen\ C2} = s_4 - s_3 = C_{P0} \ln(T_4/T_3) - R \ln (P_4/P_3)$$
$$= 1.042 \ln(530/320) - 0.2968 \ln(3000/600)$$
$$= \mathbf{0.0481\ kJ/kgK}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.103

The intercooler in the previous problem uses cold liquid water to cool the nitrogen. The nitrogen flow is 0.1 kg/s and the liquid water inlet is 20°C and setup to flow in the opposite direction as the nitrogen so the water leaves at 35°C. Find the flow rate of the water and the entropy generation in this intercooler.

Solution:



A hydraulic motor driven compressor with intercooler in small pipe between the two stages.

C.V. Heat exchanger, steady 2 flows in and two flows out.

Continuity eq.: $\dot{m}_1 = \dot{m}_2 = \dot{m}_{H2O}$; $\dot{m}_3 = \dot{m}_4 = \dot{m}_{N2}$

Energy eq.: $0 = \dot{m}_{N2}\,(h_3 - h_4) + \dot{m}_{H2O}\,(h_2 - h_1)$

Entropy Eq.7.7: $0 = \dot{m}_{N2}\,(s_3 - s_4) + \dot{m}_{H_2O}\,(s_2 - s_1) + \dot{S}_{gen}$

Due to the lower range of temperature we will use constant specific heats from A.5 and A.4 so the energy equation is approximated as

$$0 = \dot{m}_{H2O} C_{pH2O}\,(T_2 - T_1) + \dot{m}_{N2} C_p\,(T_3 - T_4)$$

Now solve for the water flow rate

$$\dot{m}_{H2O} = \dot{m}_{N2}\, C_{pN2}\,(T_3 - T_4) / [C_{pH2O}\,(T_1 - T_2)]$$

$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \times (450 - 320) \text{ K} / [4.18 \times (35 - 20) \text{ kJ/kg}]$$

$$= \mathbf{0.216 \text{ kg/s}}$$

$$\dot{S}_{gen} = \dot{m}_{N2}\,(s_4 - s_3) + \dot{m}_{H_2O}\,(s_1 - s_2)$$

$$= \dot{m}_{N2} C_P \ln (T_4/T_3) + \dot{m}_{H_2O} C_P \ln (T_1/T_2)$$

$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \ln \frac{320}{450} + 0.216 \text{ kg/s} \times 4.18 \text{ kJ/kgK} \ln \frac{308}{293}$$

$$= -0.03552 + 0.04508 = \mathbf{0.00956 \text{ kW/K}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.104

Air at 327°C, 400 kPa with a volume flow 1 m^3/s runs through an adiabatic turbine with exhaust pressure of 100 kPa. Neglect kinetic energies and use constant specific heats. Find the lowest and highest possible exit temperature. For each case find also the rate of work and the rate of entropy generation.

Solution:

C.V Turbine. Steady single inlet and exit flows, q = 0.

Inlet state: (T, P) $v_i = RT_i / P_i = 0.287 \times 600/400 = 0.4305$ m^3/kg

$\dot{m} = \dot{V}/v_i = 1/0.4305 = 2.323$ kg/s

The lowest exit T is for maximum work out i.e. reversible case

Process: Reversible and adiabatic => constant s from Eq.7.9

Eq.8.23: $T_e = T_i(P_e/P_i)^{\frac{k-1}{k}} = 600 \times (100/400)^{0.2857} =$ **403.8 K**

$\Rightarrow \quad w = h_i - h_e = C_{Po}(T_i - T_e) = 1.004 \times (600 - 403.8) = 197$ kJ/kg

$\dot{W}_T = \dot{m}w = 2.323 \times 197 =$ **457.6 kW** and $\dot{S}_{gen} =$ **0**

Highest exit T occurs when there is no work out, throttling

q = ∅; **w = ∅** $\Rightarrow \quad h_i - h_e = 0 \quad \Rightarrow \quad T_e = T_i =$ **600 K**

$$\dot{S}_{gen} = \dot{m}(s_e - s_i) = -\dot{m}R \ln \frac{P_e}{P_i} = -2.323 \times 0.287 \ln \frac{100}{400} =$$ **0.924 kW/K**

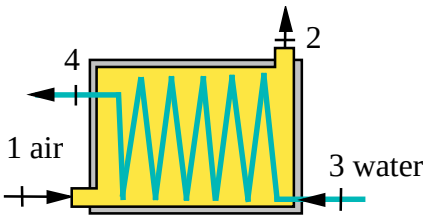
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.105

A counter flowing heat exchanger has one line with 2 kg/s at 125 kPa, 1000 K entering and the air is leaving at 100 kPa, 400 K. The other line has 0.5 kg/s water coming in at 200 kPa, 20°C and leaving at 200 kPa. What is the exit temperature of the water and the total rate of entropy generation?

Solution:

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for air and water each. The two flows exchange energy with no heat transfer to/from the outside.



Energy Eq.4.10: $\dot{m}_{AIR}\Delta h_{AIR} = \dot{m}_{H2O}\Delta h_{H2O}$

From A.7: $h_1 - h_2 = 1046.22 - 401.3 = 644.92$ kJ/kg

From B.1.2 $h_3 = 83.94$ kJ/kg; $s_3 = 0.2966$ kJ/kg K

$h_4 - h_3 = (\dot{m}_{AIR}/\dot{m}_{H2O})(h_1 - h_2) = (2/0.5)644.92 = 2579.68$ kJ/kg

$h_4 = h_3 + 2579.68 = 2663.62$ kJ/kg $< h_g$ at 200 kPa

$T_4 = T_{sat} = 120.23$°C,

$x_4 = (2663.62 - 504.68)/2201.96 = 0.9805$,

$s_4 = 1.53 + x_4\, 5.597 = 7.01786$ kJ/kg K

From entropy Eq.7.7

$$\dot{S}_{gen} = \dot{m}_{H2O}\,(s_4 - s_3) + \dot{m}_{AIR}(s_2 - s_1)$$

$$= 0.5(7.01786 - 0.2966) + 2(7.1593 - 8.1349 - 0.287 \ln (100/125))$$

$$= 3.3606 - 1.823 = \mathbf{1.54\ kW/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.106

A large supply line has a steady air flow at 500 K, 200 kPa. It is used in three different adiabatic devices shown in Fig. P9.85, a throttle flow, an ideal nozzle and an ideal turbine. All the exit flows are at 100 kPa. Find the exit temperature and specific entropy generation for each device and the exit velocity of the nozzle.

C.V. Throttle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e$ ($Z_i = Z_e$ and **V**'s are small)

Entropy Eq.7.8: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + s_{gen}$

Since it is air we have h = h(T) so same h means same $T_e = T_i =$ **500 K**

$$s_{gen} = s_e - s_i = s^o_{Te} - s^o_{Ti} - R \ln(P_e / P_i) = 0 - 0.287 \ln(1/2) = \mathbf{0.2\ kJ/kg\ K}$$

C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2$ ($Z_i = Z_e$)

Entropy Eq.7.8: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

Use constant specific heat from Table A.5, $C_{Po} = 1.004 \frac{kJ}{kg\ K}$, k = 1.4

The isentropic process ($s_e = s_i$) gives Eq.8.23

$$\Rightarrow \quad T_e = T_i(P_e/P_i)^{\frac{k-1}{k}} = 500\ (100/200)^{0.2857} = \mathbf{410\ K}$$

The energy equation becomes: $\mathbf{V}_e^2/2 = h_i - h_e \cong C_P(T_i - T_e)$

$$\mathbf{V}_e = \sqrt{2\ C_P(T_i - T_e)} = \sqrt{2 \times 1.004\ kJ/kgK\ (500\text{-}410)\ K \times 1000\ J/kJ} = \mathbf{424\ m/s}$$

Turbine:

Process: Reversible and adiabatic => constant s from Eq.7.8

Eq.6.23: $T_e = T_i(P_e/P_i)^{\frac{k-1}{k}} = 500 \times (100/200)^{0.2857} =$ **410 K**

$$\Rightarrow \quad w = h_i - h_e = C_{Po}(T_i - T_e) = 1.004 \times (500 - 410) = 90\ kJ/kg$$

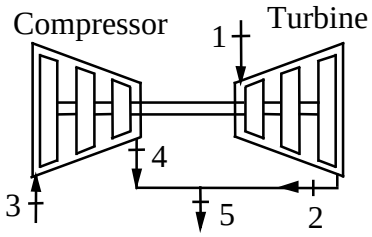
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.107

In a heat-driven refrigerator with ammonia as the working fluid, a turbine with inlet conditions of 2.0 MPa, 70°C is used to drive a compressor with inlet saturated vapor at –20°C. The exhausts, both at 1.2 MPa, are then mixed together. The ratio of the mass flow rate to the turbine to the total exit flow was measured to be 0.62. Can this be true?

Solution:

Assume the compressor and the turbine are both adiabatic.



C.V. Total:

Continuity Eq.4.11: $\dot{m}_5 = \dot{m}_1 + \dot{m}_3$

Energy Eq.4.10: $\dot{m}_5 h_5 = \dot{m}_1 h_1 + \dot{m}_3 h_3$

Entropy: $\dot{m}_5 s_5 = \dot{m}_1 s_1 + \dot{m}_3 s_3 + \dot{S}_{C.V.,gen}$

$$s_5 = y s_1 + (1\text{-}y) s_3 + \dot{S}_{C.V.,gen}/\dot{m}_5$$

Assume $y = \dot{m}_1/\dot{m}_5 = 0.62$

State 1: Table B.2.2 $h_1 = 1542.7$ kJ/kg, $s_1 = 4.982$ kJ/kg K,

State 3: Table B.2.1 $h_3 = 1418.1$ kJ/kg, $s_3 = 5.616$ kJ/kg K

Solve for exit state 5 in the energy equation

$$h_5 = y h_1 + (1\text{-}y) h_3 = 0.62 \times 1542.7 + (1 - 0.62) 1418.1 = 1495.4 \text{ kJ/kg}$$

State 5: $h_5 = 1495.4$ kJ/kg, $P_5 = 1200$ kPa $\Rightarrow$ $s_5 = 5.056$ kJ/kg K

Now check the 2nd law, entropy generation

$$\Rightarrow \dot{S}_{C.V.,gen}/\dot{m}_5 = s_5 - y s_1 - (1\text{-}y) s_3 = \mathbf{-0.1669\ Impossible}$$

The problem could also have been solved assuming a reversible process and then find the needed flow rate ratio y. Then y would have been found larger than 0.62 so the stated process can not be true.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.108

Repeat problem 7.106 for the throttle and the nozzle when the inlet air temperature is 2500 K and use the air tables.

C.V. Throttle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e$ ($Z_i = Z_e$ and **V**'s are small)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + s_{gen}$

Since it is air we have h = h(T) so same h means same $T_e = T_i =$ **2500 K**

$$s_{gen} = s_e - s_i = s^o_{Te} - s^o_{Ti} - R \ln(P_e / P_i) = 0 - 0.287 \ln(1/2) = \mathbf{0.2\ kJ/kg\ K}$$

C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2$ ($Z_i = Z_e$)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

The isentropic process ($s_e = s_i$) gives Eq.6.19

$$0 = s_e - s_i = s^o_{Te} - s^o_{Ti} - R \ln(P_e / P_i)$$

=> $s^o_{Te} = s^o_{Ti} + R \ln(P_e / P_i) = 9.24781 + 0.287 \ln (100/200) = 9.04888$

T = **2136.6 K,** $h_e = 2422.86$ kJ/kg

The energy equation becomes

$$\mathbf{V}_e^2/2 = h_i - h_e = 2883.06 - 2422.86 = 460.2 \text{ kJ/kg}$$

$$\mathbf{V}_e = \sqrt{2 \times 1000 \times 460.2} = \mathbf{959\ m/s}$$

7.109

Carbon dioxide used as a natural refrigerant flows through a cooler at 10 MPa, which is supercritical so no condensation occurs. The inlet is at 200^{o}C and the exit is at 40^{o}C. Assume the heat transfer is to the ambient at 20^{o}C and find the specific entropy generation.

C.V. Heat exchanger to ambient, steady constant pressure so no work.

Energy Eq.4.12: $h_i = h_e + q_{out}$

Entropy Eq.7.9: $s_i + s_{gen} = s_e + q_{out}/T$

Using Table B.3

$$q_{out} = (h_i - h_e) = 519.49 - 200.14 = 319.35 \text{ kJ/kg}$$

$$s_{gen} = s_e - s_i + q_{out}/T$$

$$= (0.6906 - 1.5705) \text{ kJ/kgK} + \frac{319.35 \text{ kJ/kg}}{293.15 \text{ K}} = \mathbf{0.2095 \text{ kJ/kgK}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.110

Saturated liquid nitrogen at 600 kPa enters a boiler at a rate of 0.005 kg/s and exits as saturated vapor. It then flows into a super heater also at 600 kPa where it exits at 600 kPa, 280 K. Assume the heat transfer comes from a 300 K source and find the rates of entropy generation in the boiler and the super heater.

Solution:

C.V.: boiler steady single inlet and exit flow, neglect KE, PE energies in flow

Continuity Eq.: $\dot{m}_1 = \dot{m}_2 = \dot{m}_3$

Table B.6.1: $h_1 = -81.53$ kJ/kg, $s_1 = 3.294$ kJ/kgK,

$h_2 = 86.85$ kJ/kg, $s_2 = 5.041$ kJ/kgK

Table B.6.2: $h_3 = 289.05$ kJ/kg, $s_3 = 6.238$ kJ/kgK

Energy Eq.4.13: $q_{boiler} = h_2 - h_1 = 86.85 - (-81.53) = 168.38$ kJ/kg

$$\dot{Q}_{boiler} = \dot{m}_1 q_{boiler} = 0.005 \times 168.38 = 0.842 \text{ kW}$$

Entropy Eq.: $\dot{S}_{gen} = \dot{m}_1(s_2 - s_1) - \dot{Q}_{boiler}/T_{source}$

$= 0.005(5.041-3.294) - 0.842/300 =$ **0.0059 kW/K**

C.V. Superheater (same approximations as for boiler)

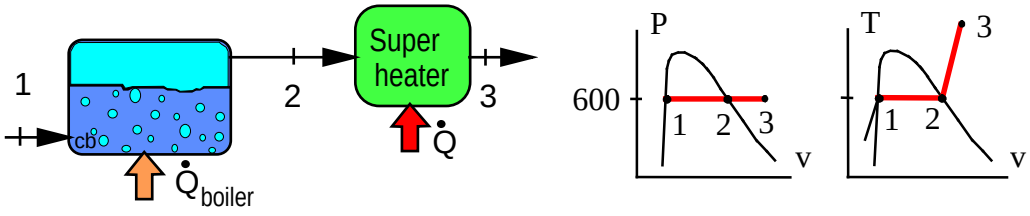
Energy Eq.4.13: $q_{sup\ heater} = h_3 - h_2 = 289.05 - 86.85 = 202.2$ kJ/kg

$$\dot{Q}_{sup\ heater} = \dot{m}_2 q_{sup\ heater} = 0.005 \text{ kg/s} \times 202.2 \text{ kJ/kg} = 1.01 \text{ kW}$$

Entropy Eq.: $\dot{S}_{gen} = \dot{m}_1(s_3 - s_2) - \dot{Q}_{sup\ heater}/T_{source}$

$= 0.005$ kg/s $(6.238-5.041)$kJ/kgK $- 1.01$ kW/300 K

$=$ **0.00262 kW/K**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.111

A steam turbine in a power plant receives steam at 3000 kPa, 500^{o}C. The turbine has two exit flows, one is 20% of the flow at 1000 kPa, 350^{o}C to a feedwater heater and the remainder flows out at 200 kPa, 200^{o}C. Find the specific turbine work and the specific entropy generation both per kg flow in.

C.V. Steam turbine (x = 0.2 = extraction fraction)

Energy Eq.4.13: $w = h_1 - xh_2 - (1 - x)h_3$

Entropy Eq.7.8: $s_2 = s_1 + s_{gen\ HP}$ (full flow rate)

Entropy Eq.7.9: $s_3 = s_2 + s_{gen\ LP}$ [flow rate is fraction (1-x)]

Overall entropy gen: $s_{gen\ HP} = s_{gen\ HP} + (1 - x)\, s_{gen\ LP}$

Inlet state: Table B.1.3 $h_1 = 3456.48$ kJ/kg; $s_1 = 7.2337$ kJ/kg K

Extraction state: $h_2 = 3157.65$ kJ/kg, $s_2 = 7.3010$ kJ/kg K

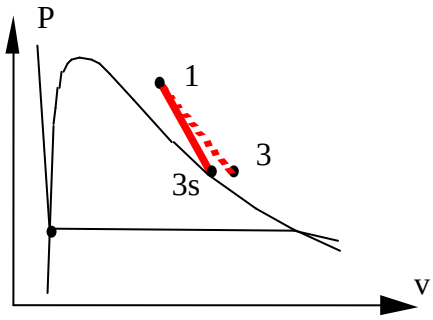
Exit (actual) state: Table B.1.3 $h_3 = 2870.46$; $s_3 = 7.5066$ kJ/kg K

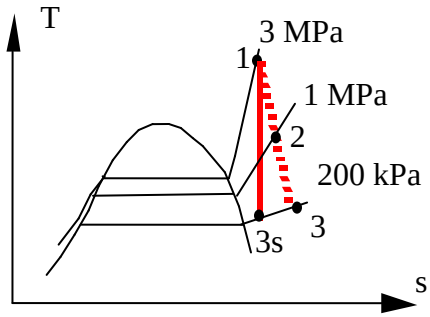
Actual turbine energy equation

$$w = 3456.48 - 0.2 \times 3157.65 - 0.8 \times 2870.46 = \mathbf{528.58\ kJ/kg}$$

$$s_{gen\ tot} = 7.301 - 7.2337 + 0.8\,(7.5066 - 7.301)$$

$$= \mathbf{0.232\ kJ/kgK}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.112

One type of feedwater heater for preheating the water before entering a boiler operates on the principle of mixing the water with steam that has been bled from the turbine. For the states as shown in Fig. P7.112, calculate the rate of net entropy increase for the process, assuming the process to be steady flow and adiabatic.

Solution:

CV: Feedwater heater, Steady flow, no external heat transfer.

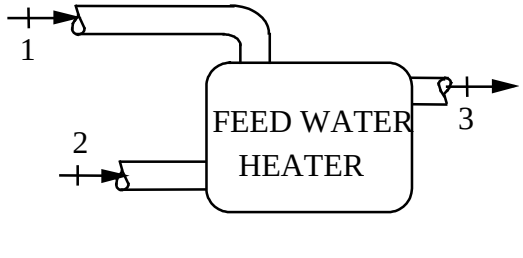
Continuity Eq.4.9: $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$

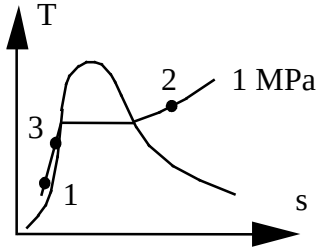
Energy Eq.4.10: $\dot{m}_1 h_1 + (\dot{m}_3 - \dot{m}_1) h_2 = \dot{m}_3 h_3$

Properties: All states are given by (P,T) table B.1.1 and B.1.3

$h_1 = 168.42$, $h_2 = 2828$, $h_3 = 675.8$ all kJ/kg

$s_1 = 0.572$, $s_2 = 6.694$, $s_3 = 1.9422$ all kJ/kg K





Solve for the flow rate from the energy equation

$$\dot{m}_1 = \frac{\dot{m}_3(h_3 - h_2)}{(h_1 - h_2)} = \frac{4(675.8 - 2828)}{(168.42 - 2828)} = 3.237 \text{ kg/s}$$

$$\Rightarrow \quad \dot{m}_2 = 4 - 3.237 = 0.763 \text{ kg/s}$$

The second law for steady flow, $\dot{S}_{CV} = 0$, and no heat transfer, Eq.7.7:

$$\dot{S}_{C.V.,gen} = \dot{S}_{SURR} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2$$

$$= 4(1.9422) - 3.237(0.572) - 0.763(6.694) = \mathbf{0.8097\ kJ/K\ s}$$

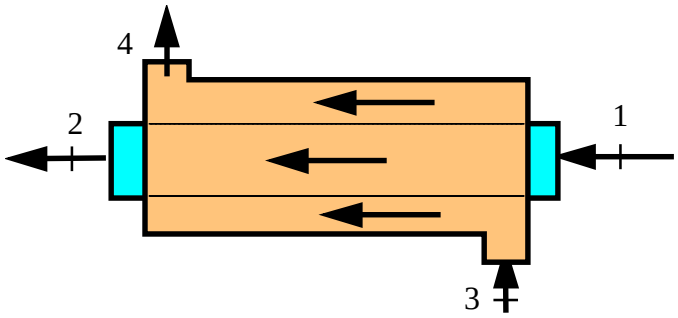
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.113

A coflowing (same direction) heat exchanger has one line with 0.5 kg/s oxygen at 17°C, 200 kPa entering and the other line has 0.6 kg/s nitrogen at 150 kPa, 500 K entering. The heat exchanger is very long so the two flows exit at the same temperature. Use constant heat capacities and find the exit temperature and the total rate of entropy generation.

Solution:

C.V. Heat exchanger, steady 2 flows in and two flows out.



Energy Eq.4.10: $\dot{m}_{O2}h_1 + \dot{m}_{N2}h_3 = \dot{m}_{O2}h_2 + \dot{m}_{N2}h_4$

Same exit temperature so $T_4 = T_2$ with values from Table A.5

$$\dot{m}_{O2}C_{P\,O2}T_1 + \dot{m}_{N2}C_{P\,N2}T_3 = (\dot{m}_{O2}C_{P\,O2} + \dot{m}_{N2}C_{P\,N2})T_2$$

$$T_2 = \frac{0.5 \times 0.922 \times 290 + 0.6 \times 1.042 \times 500}{0.5 \times 0.922 + 0.6 \times 1.042} = \frac{446.29}{1.0862}$$

$$= \mathbf{410.9\ K}$$

Entropy Eq.7.7 gives for the generation

$$\dot{S}_{gen} = \dot{m}_{O2}(s_2 - s_1) + \dot{m}_{N2}(s_4 - s_3)$$

$$= \dot{m}_{O2}C_P \ln (T_2/T_1) + \dot{m}_{N2}C_P \ln (T_4/T_3)$$

$$= 0.5 \times 0.922 \ln (410.9/290) + 0.6 \times 1.042 \ln (410.9/500)$$

$$= 0.16064 - 0.1227 = \mathbf{0.0379\ kW/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.114

A supply of 5 kg/s ammonia at 500 kPa, 20°C is needed. Two sources are available one is saturated liquid at 20°C and the other is at 500 kPa and 140°C. Flows from the two sources are fed through valves to an insulated mixing chamber, which then produces the desired output state. Find the two source mass flow rates and the total rate of entropy generation by this setup.

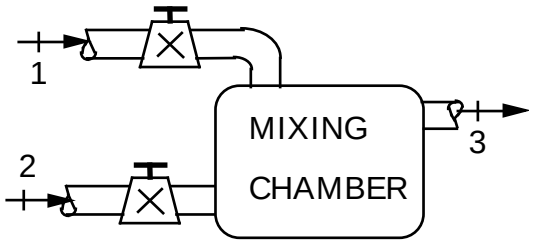
Solution:

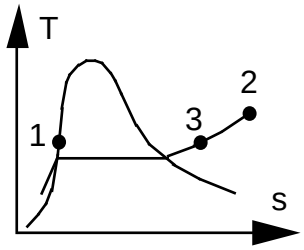
C.V. mixing chamber + valve. Steady, no heat transfer, no work.

Continuity Eq.4.9: $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$;

Energy Eq.4.10: $\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen} = \dot{m}_3 s_3$





State 1: Table B.2.1 $h_1 = 273.4$ kJ/kg, $s_1 = 1.0408$ kJ/kg K

State 2: Table B.2.2 $h_2 = 1773.8$ kJ/kg, $s_2 = 6.2422$ kJ/kg K

State 3: Table B.2.2 $h_3 = 1488.3$ kJ/kg, $s_3 = 5.4244$ kJ/kg K

As all states are known the energy equation establishes the ratio of mass flow rates and the entropy equation provides the entropy generation.

$$\dot{m}_1 h_1 + (\dot{m}_3 - \dot{m}_2) h_2 = \dot{m}_3 h_3 \quad \Rightarrow \quad \dot{m}_1 = \dot{m}_3 \frac{h_3 - h_2}{h_1 - h_2} = 0.952 \text{ kg/s}$$

$$\dot{m}_2 = \dot{m}_3 - \dot{m}_1 = 4.05 \text{ kg/s}$$

$$\dot{S}_{gen} = (5 \times 5.4244 - 0.95 \times 1.0408 - 4.05 \times 6.2422) \text{ (kg/s)} \times \text{(kJ/kgK)}$$

$$= \mathbf{0.852\ kW/K}$$

7.115

Calculate the specific entropy generated in the filling process given in Example 4.10.

Solution:

C.V. Cannister filling process where: ${}_1Q_2 = 0$; ${}_1W_2 = 0$; $m_1 = 0$

Continuity Eq.4.15: $m_2 - 0 = m_{in}$;

Energy Eq.4.16: $m_2u_2 - 0 = m_{in}h_{line} + 0 + 0 \quad \Rightarrow \quad u_2 = h_{line}$

Entropy Eq.7.12: $m_2s_2 - 0 = m_{in}s_{line} + 0 + {}_1S_{2\ gen}$

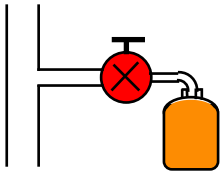
Inlet state : 1.4 MPa, 300°C, $h_i = 3040.4$ kJ/kg, $s_i = 6.9533$ kJ/kg K

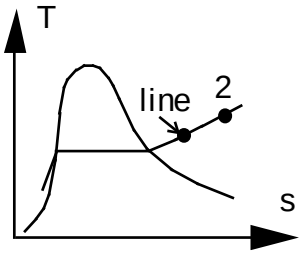
final state: 1.4 MPa, $u_2 = h_i = 3040.4$ kJ/kg

$\Rightarrow$ $T_2 = 452$°C, $s_2 = 7.45896$ kJ/kg K

${}_1S_{2\ gen} = m_2(s_2 - s_i)$

${}_1s_{2\ gen} = s_2 - s_i = 7.45896 - 6.9533 =$ **0.506 kJ/kg K**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.116

A 1-m^3 rigid tank contains 100 kg R-410A at a temperature of 15°C. A valve on top of the tank is opened, and saturated vapor is throttled to ambient pressure, 100 kPa, and flows to a collector system. During the process the temperature inside the tank remains at 15°C by heat transfer from the 20°C ambient. The valve is closed when no more liquid remains inside. Calculate the heat transfer to the tank and total entropy generation in the process.

Solution:

C.V. Tank out to surroundings. Rigid tank so no work term.

Continuity Eq.4.15: $m_2 - m_1 = - m_e$;

Energy Eq.4.16: $m_2u_2 - m_1u_1 = Q_{CV} - m_eh_e$

Entropy Eq.7.12: $m_2s_2 - m_1s_1 = Q_{CV}/T_{SUR} - m_es_e + S_{gen}$

State 1: Table B.4.1, $v_1 = V_1/m_1 = 1/100 = 0.000904 + x_1\ 0.01955$

$x_1 = 0.46527$, $u_1 = 80.02 + 0.46527 \times 177.1 = 162.42$ kJ/kg

$s_1 = 0.3083 + 0.46527 \times 0.6998 = 0.6339$; $h_e = h_g = 282.79$ kJ/kg

State 2: $v_2 = v_g = 0.02045$, $u_2 = u_g = 257.12$, $s_2 = 1.0081$ kJ/kg K

Exit state: $h_e = 282.79$, $P_e = 100$ kPa $\rightarrow T_e = -18.65$°C, $s_e = 1.2917$ kJ/kgK

$m_2 = 1/0.02045 = 48.9$ kg; $m_e = 100 - 48.9 = 51.1$ kg

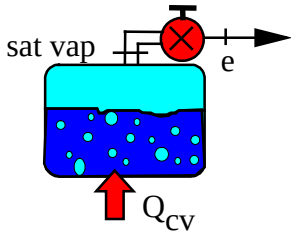
$Q_{CV} = m_2u_2 - m_1u_1 + m_eh_e$

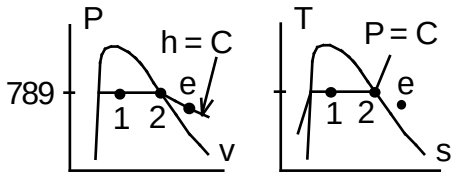
$= 48.9 \times 257.12 - 100 \times 162.42 + 51.1 \times 282.79 =$ **10 782 kJ**

$S_{gen} = m_2s_2 - m_1s_1 + m_es_e - Q_{CV}/T_{SUR}$

$= 48.9 \times 1.0081 - 100 \times 0.6339 + 51.1 \times 1.2917 - 10\ 782 / 293.15$

$=$ **15.14 kJ/K**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.117

A 0.2 m^3 initially empty container is filled with water from a line at 500 kPa, 200 °C until there is no more flow. Assume the process is adiabatic and find the final mass, final temperature and the total entropy generation.

Solution:

C.V. The container volume and any valve out to line.

Continuity Eq.4.15: $m_2 - m_1 = m_2 = m_i$

Energy Eq.4.16: $m_2u_2 - m_1u_1 = m_2u_2 = {}_1Q_2 - {}_1W_2 + m_ih_i = m_ih_i$

Entropy Eq.7.12: $m_2s_2 - m_1s_1 = m_2s_2 = \int dQ/T + {}_1S_{2\ gen} + m_is_i$

Process: Adiabatic ${}_1Q_2 = 0$, Rigid ${}_1W_2 = 0$ Flow stops $P_2 = P_{line}$

State i: $h_i = 2855.37$ kJ/kg; $s_i = 7.0592$ kJ/kg K

State 2: 500 kPa, $u_2 = h_i = 2855.37$ kJ/kg => Table B.1.3

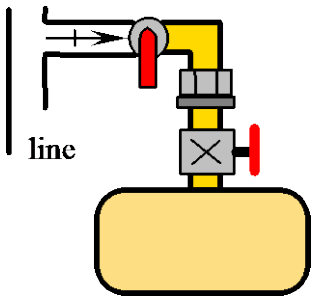
$T_2 \cong$ **332.9°C** , $s_2 = 7.5737$ kJ/kg, $v_2 = 0.55387$ m^3/kg

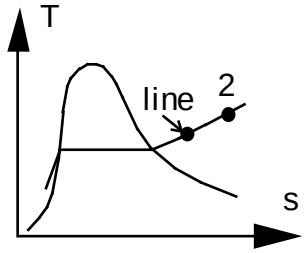
$m_2 = V/v_2 = 0.2/0.55387 =$ **0.361 kg**

From the entropy equation

${}_1S_{2\ gen} = m_2s_2 - m_2s_i$

$= 0.361(7.5737 – 7.0592) =$ **0.186 kJ/K**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.118

An initially empty 0.1 m^3 cannister is filled with R-410A from a line flowing saturated liquid at –5°C. This is done quickly such that the process is adiabatic. Find the final mass, liquid and vapor volumes, if any, in the cannister. Is the process reversible?

Solution:

C.V. Cannister filling process where: $_1Q_2 = 0$; $_1W_2 = 0$; $m_1 = 0$

Continuity Eq.4.15: $m_2 - 0 = m_{in}$;

Energy Eq.4.16: $m_2u_2 - 0 = m_{in}h_{line} + 0 + 0 \Rightarrow u_2 = h_{line}$

1: Table B.4.1 $u_f = 49.65$, $u_{fg} = 201.75$, $h_f = 50.22$ all kJ/kg

2: $P_2 = P_{line}$; $u_2 = h_{line} \Rightarrow$ 2 phase $u_2 > u_f$; $u_2 = u_f + x_2u_{fg}$

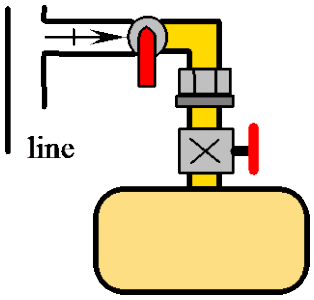
$x_2 = (50.22 - 49.65)/201.75 = 0.002825$

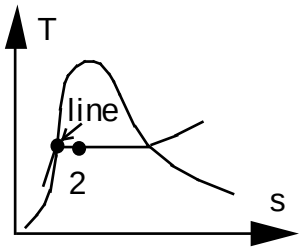
$\Rightarrow v_2 = v_f + x_2v_{fg} = 0.000841 + 0.002825 \times 0.03764 = 0.0009473$ m^3/kg

$\Rightarrow m_2 = V/v_2 =$ **105.56 kg** ; $m_f = 106.262$ kg; $m_g = 0.298$ kg

$V_f = m_f v_f =$ **0.089** m^3; $V_g = m_g v_g =$ **0.0115** $\mathbf{m^3}$

Process is irreversible (throttling) $s_2 > s_f$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.119

A 1 L can of R-134a is at room temperature 20°C with a quality of 50%. A leak in the top valve allows vapor to escape and heat transfer from the room takes place so we reach final state of 5°C with a quality of 100%. Find the mass that escaped, the heat transfer and the entropy generation not including that made in the valve.

CV The can of R-134a not including the nozzle/valve out to ambient 20°C

Continuity Eq.: $m_2 - m_1 = - m_e$

Energy Eq.: $m_2u_2 - m_1u_1 = - m_eh_e + {}_1Q_2 - {}_1W_2$

Entropy Eq.7.12: $m_2s_2 - m_1s_1 = - m_es_e + \int dQ/T + {}_1S_{2\ gen}$

Process Eq.: V = constant => ${}_1W_2 = \int PdV = 0$

State 1: (T,x) $v_1 = v_f + x_1v_{fg} = 0.000817 + 0.5\ 0.03524 = 0.018437\ m^3/kg$

$u_1 = u_f + x_1u_{fg} = 227.03 + 0.5\ 162.16 = 308.11\ kJ/kg$

$s_1 = s_f + x_1s_{fg} = 1.0963 + 0.5\ 0.622 = 1.4073\ kJ/kg$

$m_1 = V / v_1 = 0.001 / 0.018437 = 0.05424\ kg$

State 2: (T,x)

$v_2 = v_g = 0.05833\ m^3/kg$, $u_2 = u_g = 380.85\ kJ/kg$, $s_2 = s_g = 1.7239\ kJ/kg\ K$

$m_2 = V/v_2 = 0.001 / 0.05833 = 0.017144\ kg$

Exit state e: Saturated vapor starting at 20°C ending at 5°C so we take an average

$h_e = 0.5(h_{e1} + h_{e2}) = 0.5\ (409.84 + 401.32) = 405.58\ kJ/kg$

$s_e = 0.5(s_{e1} + s_{e2}) = 0.5\ (1.7183 + 1.7239) = 1.7211\ kJ/kg\ K$

$m_e = m_1 - m_2 =$ **0.0371 kg**

The heat transfer from the energy equation becomes

${}_1Q_2 = m_2u_2 - m_1u_1 + m_eh_e = 6.5293 - 16.7119 + 15.047 =$ **4.864 kJ**

${}_1S_{2\ gen} = m_2s_2 - m_1s_1 + m_es_e - {}_1Q_2/T_{amb}$

$= 0.029555 - 0.076332 + 0.063853 - 0.016592 =$ **0.000484 kJ/K**

7.121

A cook filled a pressure cooker with 3 kg water at 20°C and a small amount of air and forgot about it. The pressure cooker has a vent valve so if P > 200 kPa steam escapes to maintain a pressure of 200 kPa. How much entropy was generated in the throttling of the steam through the vent to 100 kPa when half the original mass has escaped?

Solution:

The pressure cooker goes through a transient process as it heats water up to the boiling temperature at 200 kPa then heats more as saturated vapor at 200 kPa escapes. The throttling process is steady state as it flows from saturated vapor at 200 kPa to 100 kPa which we assume is a constant h process.

C.V. Pressure cooker, no work.

Continuity Eq.6.15: $m_2 - m_1 = -m_e$

Energy Eq.6.16: $m_2 u_2 - m_1 u_1 = -m_e h_e + {}_1Q_2$

Entropy Eq.7.12: $m_2 s_2 - m_1 s_1 = -m_e s_e + \int dQ/T + {}_1S_{2\,gen}$

State 1: $v_1 = v_f = 0.001002\ m^3/kg$ $\quad V = m_1 v_1 = 0.003006\ m^3$

State 2: $m_2 = m_1/2 = 1.5$ kg, $v_2 = V/m_2 = 2v_1$, $P_2 = 200$ kPa

Exit: $h_e = h_g = 2706.63$ kJ/kg, $s_e = s_g = 7.1271$ kJ/kg K

So we can find the needed heat transfer and entropy generation if we know the C.V. surface temperature T. If we assume T for water then ${}_1S_{2\,gen} = 0$, which is an internally reversible externally irreversible process, there is a ΔT between the water and the source.

C.V. Valve, steady flow from state e (200 kPa) to state 3 (at 100 kPa).

Energy Eq.: $h_3 = h_e$

Entropy Eq.: $s_3 = s_e + {}_es_{3\,gen}$ generation in valve (throttle)

State 3: 100 kPa, $h_3 = 2706.63$ kJ/kg Table B.1.3 $\Rightarrow$

$$T_3 = 99.62 + (150\text{-}99.62)\,\frac{2706.63 - 2675.46}{2776.38 - 2675.46} = 115.2°C$$

$$s_3 = 7.3593 + (7.6133 - 7.3593)\ 0.30886 = 7.4378\ kJ/kg\ K$$

$${}_eS_{3\,gen} = m_e(s_3 - s_e) = 1.5\ (7.4378 - 7.1271) = \mathbf{0.466\ kJ/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.122

A 10 m tall 0.1 m diameter pipe is filled with liquid water at 20°C. It is open at the top to the atmosphere, 100 kPa, and a small nozzle is mounted in the bottom. The water is now let out through the nozzle splashing out to the ground until the pipe is empty. Find the water initial exit velocity, the average kinetic energy in the exit flow and the total entropy generation for the process.

Total mass: $m = \rho AH = \rho \frac{\pi}{4} D^2 H = 998 \frac{\pi}{4} 0.1^2 \times 10 = 78.383$ kg

Bernoulli: $\frac{1}{2}\mathbf{V}^2 = gH \quad \Rightarrow \quad \mathbf{V}_1 = \sqrt{2gH_1} = \sqrt{2 \times 9.807 \times 10} =$ **14 m/s**

$$\frac{1}{2}\mathbf{V}_{avg}^2 = gH_{avg} = g\frac{1}{2}H_1 = 9.807 \times 5 = \mathbf{49\ m^2/s^2} \quad \text{(J/kg)}$$

All the energy (average kinetic energy) is dispersed in the ambient at 20°C so

$$S_{gen} = \frac{Q}{T} = \frac{m}{2T}\mathbf{V}_{avg}^2 = \frac{78.383 \text{ kg} \times 49 \text{ J/kg}}{293.15 \text{ K}} = \mathbf{13.1\ J/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.123

A 200 L insulated tank contains nitrogen gas at 200 kPa, 300 K. A line with nitrogen at 500 K, 500 kPa adds 40% more mass to the tank with a flow through a valve. Use constant specific heats to find the final temperature and the entropy generation.

C.V. Tank, no work and no heat transfer.

Continuity Eq.6.15: $m_2 - m_1 = m_i$

Energy Eq.6.16: $m_2 u_2 - m_1 u_1 = m_i h_i + {}_1Q_2$

Entropy Eq.7.12: $m_2 s_2 - m_1 s_1 = m_i s_i + \int dQ/T + {}_1S_{2\,gen}$

Process Eq.: ${}_1Q_2 = 0, \quad m_2 = 1.4\, m_1; \quad m_i = 0.4\, m_1$

Write $h_i = u_i + RT_i$ then the energy equation contains only u's so we can substitute the u differences with $C_{v0}\,\Delta T$ and divide by $m_2\, C_{v0}$ to get

$$T_2 = \frac{m_1}{m_2} T_1 + \frac{m_i}{m_2} T_i + \frac{m_i}{m_2} \frac{R}{C_{v0}} T_i$$

$$= \frac{1}{1.4} 300 + \frac{0.4}{1.4} 500 + \frac{0.4}{1.4} \frac{0.2968}{0.745} 500 = \mathbf{414.0\ K}$$

We need the pressure for the entropy

$$P_2 = m_2 R T_2 / V = 1.4\, P_1 \times T_2/T_1 = 1.4 \times 200 \times 414/300 = 386.4\ \text{kPa}$$

$$m_1 = \frac{P_1 V_1}{RT_1} = \frac{200 \times 0.2}{0.2968 \times 300} = 0.4492\ \text{kg}; \quad m_2 = 1.4\, m_1 = 0.6289\ \text{kg}$$

The entropy generation, with entropy difference from Eq.6.16, becomes

$${}_1S_{2\,gen} = m_2 s_2 - m_1 s_1 - m_i s_i = m_2(s_2 - s_i) - m_1(s_1 - s_i)$$

$$= m_2 \left[C_{P0} \ln\left(\frac{T_2}{T_i}\right) - R \ln\left(\frac{P_2}{P_i}\right)\right] - m_1 \left[C_{P0} \ln\left(\frac{T_1}{T_i}\right) - R \ln\left(\frac{P_1}{P_i}\right)\right]$$

$$= 0.6289\left[1.042 \ln\left(\frac{414}{500}\right) - 0.2968 \ln\left(\frac{386.4}{500}\right)\right]$$

$$- 0.4492 \left[1.042 \ln\left(\frac{300}{500}\right) - 0.2968 \ln\left(\frac{200}{500}\right)\right]$$

$$= \mathbf{0.0414\ kJ/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.124

A 200 L insulated tank contains nitrogen gas at 200 kPa, 300 K. A line with nitrogen at 1500 K, 1000 kPa adds 40% more mass to the tank with a flow through a valve. Use table A.8 to find the final temperature and the entropy generation.

C.V. Tank, no work and no heat transfer.

Continuity Eq.6.15: $m_2 - m_1 = m_i$

Energy Eq.6.16: $m_2 u_2 - m_1 u_1 = m_i h_i + {}_1Q_2$

Entropy Eq.7.12: $m_2 s_2 - m_1 s_1 = m_i s_i + \int dQ/T + {}_1S_{2\,gen}$

Process Eq.: ${}_1Q_2 = 0, \quad m_2 = 1.4\, m_1; \quad m_i = 0.4\, m_1$

The energy equation can be solved for u_2 to get

$$u_2 = \frac{m_1}{m_2} u_1 + \frac{m_i}{m_2} h_i = \frac{1}{1.4} 222.63 + \frac{0.4}{1.4} 1235.5 = 512.02 \text{ kJ/kg}$$

A.8: $T_2 = 679.8$ K, $s^o_{T2} = 7.7088$ kJ/kgK, $s^o_{T1} = 6.8463$, $s^o_{Ti} = 8.6345$ kJ/kgK

We need the pressure for the entropy

$$P_2 = m_2 R T_2/V = 1.4\, P_1 \times T_2/T_1 = 1.4 \times 200 \times 679.8/300 = 634.5 \text{ kPa}$$

$$m_1 = \frac{P_1 V_1}{R T_1} = \frac{200 \times 0.2}{0.2968 \times 300} = 0.4492 \text{ kg}; \quad m_2 = 1.4\, m_1 = 0.6289 \text{ kg}$$

The entropy generation, with entropy difference from Eq.6.19, becomes

$${}_1S_{2\,gen} = m_2 s_2 - m_1 s_1 - m_i s_i = m_2(s_2 - s_i) - m_1(s_1 - s_i)$$

$$= m_2 [s^o_{T2} - s^o_{Ti} - R \ln(\frac{P_2}{P_i})] - m_1 [s^o_{T1} - s^o_{Ti} - R \ln(\frac{P_1}{P_i})]$$

$$= 0.6289[\, 7.7088 - 8.6345 - 0.2968 \ln(\frac{634.5}{1000})]$$

$$- 0.4492\, [6.8463 - 8.6345 - 0.2968 \ln(\frac{200}{1000})]$$

$$= \mathbf{0.0914 \text{ kJ/K}}$$

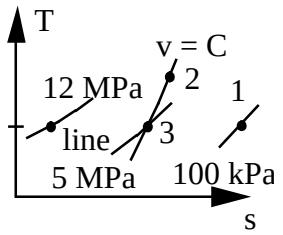
7.125

Air from a line at 12 MPa, 15°C, flows into a 500-L rigid tank that initially contained air at ambient conditions, 100 kPa, 15°C. The process occurs rapidly and is essentially adiabatic. The valve is closed when the pressure inside reaches some value, P_2. The tank eventually cools to room temperature, at which time the pressure inside is 5 MPa. What is the pressure P_2? What is the net entropy change for the overall process?

Solution:

CV: Tank. Mass flows in, so this is transient. Find the mass first

$$m_1 = P_1V/RT_1 = \frac{100 \times 0.5}{0.287 \times 288.2} = 0.604 \text{ kg}$$



Fill to P_2, then cool to $T_3 = 15°C$, $P_3 = 5$ MPa

$$m_3 = m_2 = P_3V/RT_3$$

$$= \frac{5000 \times 0.5}{0.287 \times 288.2} = 30.225 \text{ kg}$$

Mass: $m_i = m_2 - m_1 = 30.225 - 0.604 = 29.621$ kg

In the process 1-2 heat transfer = 0

Energy Eq.4.16: $m_ih_i = m_2u_2 - m_1u_1$; $m_iC_{P0}T_i = m_2C_{v0}T_2 - m_1C_{v0}T_1$

$$T_2 = \frac{(29.621 \times 1.004 + 0.604 \times 0.717) \times 288.2}{30.225 \times 0.717} = 401.2 \text{ K}$$

$P_2 = m_2RT_2/V = (30.225 \times 0.287 \times 401.2)/0.5 =$ **6.960 MPa**

Consider now the total process from the start to the finish at state 3.

Energy Eq.4.16: $Q_{CV} + m_ih_i = m_2u_3 - m_1u_1 = m_2h_3 - m_1h_1 - (P_3 - P_1)V$

But, since $T_i = T_3 = T_1$, $m_ih_i = m_2h_3 - m_1h_1$

$\Rightarrow Q_{CV} = -(P_3 - P_1)V = -(5000 - 100)0.5 = -2450$ kJ

From Eq.7.13 also Eqs.7.24-7.26

$$S_{gen} = m_3s_3 - m_1s_1 - m_is_i - Q_{CV}/T_0 = m_3(s_3 - s_i) - m_1(s_1 - s_i) - Q_{CV}/T_0$$

$$= 30.225\left[0\text{-}0.287 \ln \frac{5}{12}\right] - 0.604\left[0\text{-}0.287 \ln \frac{0.1}{12}\right] + (2450 / 288.2)$$

= **15.265 kJ/K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.126

An insulated piston/cylinder contains 0.1 m^3 air at 250 kPa, 300 K and it maintains constant pressure. More air flows in through a valve from a line at 300 kPa, 400 K so the volume increases 60%. Use constant specific heats to solve for the final temperature and the total entropy generation.

C.V. Piston/cylinder volume, no heat transfer.

Continuity Eq.6.15: $m_2 - m_1 = m_i$

Energy Eq.6.16: $m_2 u_2 - m_1 u_1 = m_i h_i - {}_1W_2$

Entropy Eq.7.12: $m_2 s_2 - m_1 s_1 = m_i s_i + \int dQ/T + {}_1S_{2\,gen}$

Process Eq.: ${}_1Q_2 = 0,\ V_2 = 1.6\ V_1;\ P = C,$

$${}_1W_2 = P(V_2 - V_1) = P_1(1.6 - 1)V_1 = 0.6\ P_1V_1 = 0.6\ m_1RT_1$$

$$m_1 = P_1V_1/RT_1 = \frac{250 \times 0.1}{0.287 \times 300} = 0.2904\ \text{kg};$$

Write $h_i = u_i + RT_i$ then the energy equation contains only u's so we can substitute the u differences with $C_{v0}\,\Delta T$ and get

$$m_2C_{v0}T_2 - m_1C_{v0}T_1 = m_iC_{v0}T_i + m_iRT_i - 0.6\ m_1RT_1$$

$$m_2T_2 = m_1T_1 + m_iT_i\,[1 + (R/C_{v0})] - 0.6\ m_1T_1R/C_{v0}$$

In this equation m_2, T_2 and m_i are unknows however we also have

$$m_2T_2 = P_2V_2/R = 1.6\ P_1V_1/R = 1.6\ m_1T_1$$

so we can solve for the mass m_i.

$$m_iT_i\,[1 + (R/C_{v0})] = 1.6\ m_1T_1 - m_1T_1 + 0.6\ m_1T_1R/C_{v0}$$

$$m_iT_i\,[1 + (R/C_{v0})] = 0.6\,[1 + R/C_{v0}]\ m_1T_1$$

$$m_i = 0.6\ m_1\,(T_1/T_i) = 0.6 \times 0.2904\ (300/400) = 0.13068\ \text{kg}$$

$$m_2 = m_i + m_1 = 0.42108\ \text{kg};\quad T_2 = 1.6\,(m_1/m_2)\,T_1 = \mathbf{331\ K}$$

The entropy generation, with entropy difference from Eq.6.16, becomes

$${}_1S_{2\,gen} = m_2s_2 - m_1s_1 - m_i s_i = m_2(s_2 - s_i) - m_1(s_1 - s_i)$$

$$= m_2\,[C_{P0}\ln(\frac{T_2}{T_i}) - R\,\ln(\frac{P_2}{P_i})] - m_1\,[C_{P0}\,\ln(\frac{T_1}{T_i}) - R\,\ln(\frac{P_1}{P_i})]$$

$$= 0.42108[\ 1.004\,\ln(\frac{331}{400}) - 0.287\,\ln(\frac{250}{300})]$$

$$- 0.2904\,[1.004\,\ln(\frac{300}{400}) - 0.287\,\ln(\frac{250}{300})]$$

$$= \mathbf{0.0107\ kJ/K}$$

Device efficiency

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

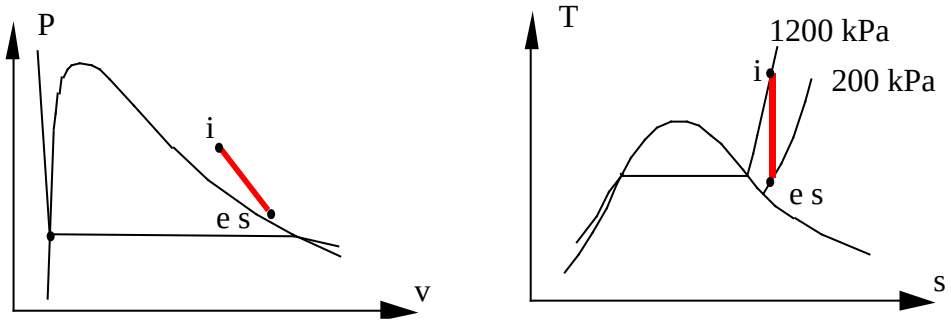
7.128

A steam turbine inlet is at 1200 kPa, 400^{o}C. The exit is at 200 kPa. What is the lowest possible exit temperature? Which efficiency does that correspond to?

We would expect the lowest possible exit temperature when the maximum amount of work is taken out. This happens in a reversible process so if we assume it is adiabatic this becomes an isentropic process.

Exit: 200 kPa, $s = s_{in} = 7.3773$ kJ/kg K $\Rightarrow$ **T = 171.5^{o}C**

The efficiency from Eq.7.27 measures the turbine relative to an isentropic turbine, so the **efficiency** will be **100%**.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

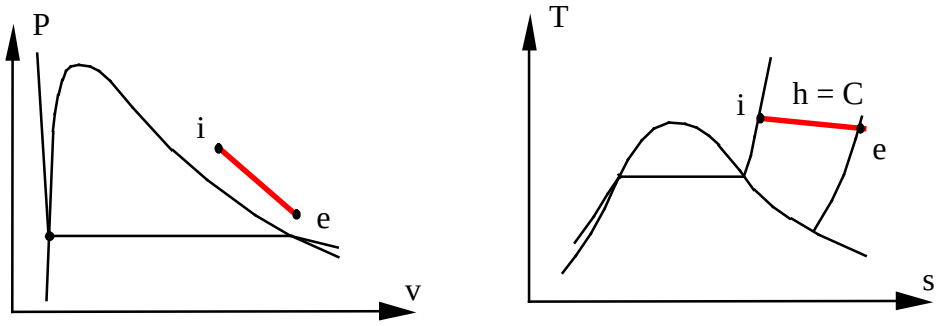
7.129

A steam turbine inlet is at 1200 kPa, 400°C. The exit is at 200 kPa. What is the highest possible exit temperature? Which efficiency does that correspond to?

The highest possible exit temperature would be if we did not get any work out, i.e. the turbine broke down. Now we have a throttle process with constant h assuming we do not have a significant exit velocity.

Exit: 200 kPa, $h = h_{in} = 3260.66$ kJ/kg $\Rightarrow$ **T = 392°C**

Efficiency: $\eta = \frac{w}{w_s} = \mathbf{0}$



Remark: Since process is irreversible there is no area under curve in T-s diagram that correspond to a q, nor is there any area in the P-v diagram corresponding to a shaft work.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

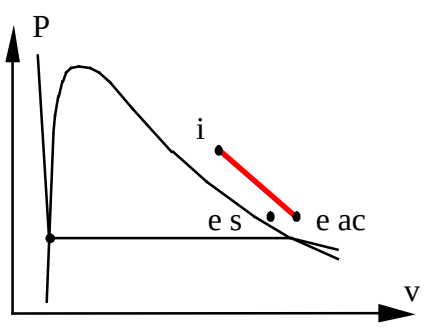
7.130

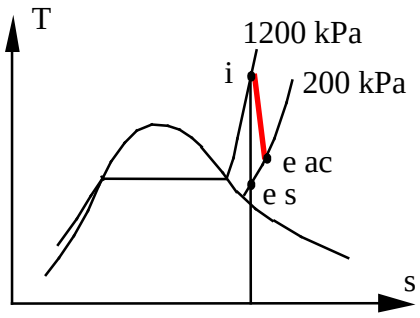
A steam turbine inlet is at 1200 kPa, 400°C. The exit is at 200 kPa, 200°C. What is the isentropic efficiency?

Inlet: h_{in} = 3260.66 kJ/kg, s_{in} = 7.3773 kJ/kg K
Exit: h_{ex} = 2870.46 kJ/kg, s_{ex} = 7.5066 kJ/kg K
Ideal Exit: 200 kPa, s = s_{in} = 7.3773 kJ/kg K $\Rightarrow$ h_s = 2812.6 kJ/kg

$w_{ac} = h_{in} - h_{ex} = 3260.66 - 2870.46 = 390.2$ kJ/kg
$w_s = h_{in} - h_s = 3260.66 - 2812.6 = 448.1$ kJ/kg

$$\eta = \frac{w_{ac}}{w_s} = \frac{390.2}{448.1} = \mathbf{0.871}$$





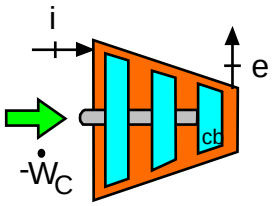
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.131

A compressor in a commercial refrigerator receives R-410A at -25°C and x = 1. The exit is at 2000 kPa and 80°C. Neglect kinetic energies and find the isentropic compressor efficiency.

Solution:

C.V. Compressor, steady state, single inlet and exit flow. For this device we also assume no heat transfer q = 0 and $Z_1 = Z_2$



Energy Eq.4.13: $h_i + 0 = w_C + h_e$;

Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e = s_i + 0 + s_{gen}$

From Table B.4.1 : $h_i = 269.77$ kJ/kg, $s_i = 1.0893$ kJ/kgK

From Table B.4.2 : $h_e = 343.22$ kJ/kg, $s_e = 1.1537$ kJ/kgK

Energy equation gives

$$w_{C\,ac} = h_i - h_e = 269.77 - 343.22 = -73.45 \text{ kJ/kgK}$$

The ideal compressor has an exit state e,s: 2000 kPa, 1.0893 kJ/kgK

Table B.4.2 $\Rightarrow$ $T_{e\,s} \cong 60.45°C$, $h_{e\,s} = 321.13$ kJ/kg

$$w_{C\,s} = 269.77 - 321.13 = -51.36 \text{ kJ/kg}$$

The isentropic efficiency measures the actual compressor to the ideal one

$$\eta = w_{C\,s} / w_{C\,ac} = -51.36 / (-73.45) = \mathbf{0.70}$$

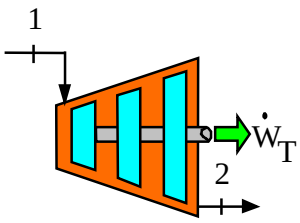
7.132

A steam turbine has an inlet of 2 kg/s water at 1000 kPa and 400°C with velocity of 15 m/s. The exit is at 100 kPa, 150°C and very low velocity. Find the power produced and the rate of entropy generation.

Solution:

C.V. Turbine. Steady flow and adiabatic.



Continuity Eq.6.9: $\dot{m}_1 = \dot{m}_2$;

Energy Eq.6.10: $\dot{m}_1(h_1 + \frac{1}{2}\mathbf{V}^2) = \dot{m}_2 h_2 + \dot{W}$

Entropy Eq.9.7: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2$

States from Table B.1.3: $h_1 = 3263.88$ kJ/kg, $s_1 = 7.4650$ kJ/kgK,

$h_2 = 2776.38$ kJ/kg, $s_2 = 7.6133$ kJ/kgK

$$\dot{W} = \dot{m}_1 (h_1 + \tfrac{1}{2}\mathbf{V}^2 - h_2) = 2 \text{ kg/s } (3263.88 + \tfrac{1}{2}\frac{15^2}{1000} - 2776.38) \text{ kJ/kg}$$

$$= \mathbf{975\ kW}$$

$$\dot{S}_{gen} = \dot{m}_1(s_2 - s_1) = 2 \text{ kg/s } (7.6133 - 7.465) \text{ kJ/kgK} = \mathbf{0.297\ kW/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.133

The exit velocity of a nozzle is 500 m/s. If $\eta_{nozzle} = 0.88$ what is the ideal exit velocity?

The nozzle efficiency is given by Eq. 7.29 and since we have the actual exit velocity we get

$$\mathbf{V}_{e\,s}^2 = \mathbf{V}_{ac}^2/\eta_{nozzle} \quad \Rightarrow$$
$$\mathbf{V}_{e\,s} = \mathbf{V}_{ac}/\sqrt{\eta_{nozzle}} = 500 / \sqrt{0.88} = \mathbf{533\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.134

An emergency drain pump should be able to pump 0.1 m^3/s liquid water at 15°C, 10 m vertically up delivering it with a velocity of 20 m/s. It is estimated that the pump, pipe and nozzle have a combined isentropic efficiency expressed for the pump as 60%. How much power is needed to drive the pump?

Solution:

C.V. Pump, pipe and nozzle together. Steady flow, no heat transfer.

Consider the ideal case first (it is the reference for the efficiency).

Energy Eq.4.12: $\dot{m}_i(h_i + \mathbf{V}^2_i/2 + gZ_i) + \dot{W}_{in} = \dot{m}_e(h_e + \mathbf{V}^2_e/2 + gZ_e)$

Solve for work and use reversible process Eq.7.15

$$\dot{W}_{ins} = \dot{m}\,[h_e - h_i + (\mathbf{V}^2_e - \mathbf{V}^2_i)/2 + g(Z_e - Z_i)]$$

$$= \dot{m}[(P_e - P_i)v + \mathbf{V}^2_e/2 + g\Delta Z]$$

$$\dot{m} = \dot{V}/v = 0.1/0.001001 = 99.9 \text{ kg/s}$$

$$\dot{W}_{ins} = 99.9[0 + (20^2/2) \times (1/1000) + 9.807 \times (10/1000)]$$

$$= 99.9(0.2 + 0.09807) = 29.8 \text{ kW}$$

With the estimated efficiency the actual work, Eq.7.28 is

$$\dot{W}_{in\ actual} = \dot{W}_{in\ s}/\eta = 29.8/0.6 = 49.7 \text{ kW} = \mathbf{50\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.135

Find the isentropic efficiency of the R-134a compressor in Example 4.8

Solution:

State 1: Table B.5.2 $h_1 = 387.2$ kJ/kg; $s_1 = 1.7665$ kJ/kg K

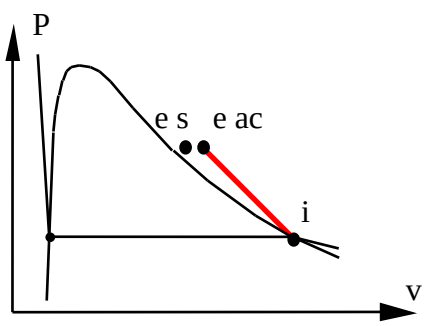
State 2ac: $h_2 = 435.1$ kJ/kg

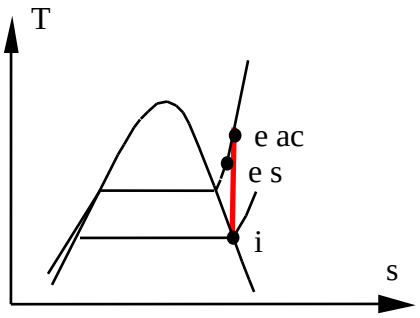
State 2s: s = 1.7665 kJ/kg K, 800 kPa => h = 431.8 kJ/kg; T = 46.8°C

$-w_{c\,s} = h_{2s} - h_1 = 431.8 - 387.2 = 44.6$ kJ/kg

$-w_{ac} = 5/0.1 = 50$ kJ/kg

$\eta = w_{c\,s}/ w_{ac} = 44.6/50 =$ **0.89**



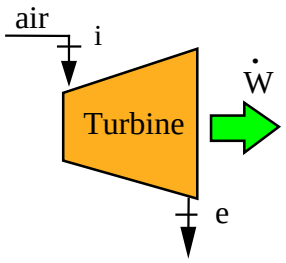


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.136

A gas turbine with air flowing in at 1200 kPa, 1200 K has an exit pressure of 200 kPa and an isentropic efficiency of 87%. Find the exit temperature.

Solution:



C.V. Ideal air turbine.

Adiabatic: $q = 0$, reversible: $s_{gen} = 0$

Energy Eq.4.13: $w_T = h_i - h_e$,

Entropy Eq.7.9: $s_e = s_i$

Table A.7: $h_i = 1277.8$ kJ/kg, $s^o_{Ti} = 8.34596$ kJ/kg K

The constant s process is written from Eq.6.19 as

$$\Rightarrow s^o_{Te} = s^o_{Ti} + R \ln(\frac{P_e}{P_i}) = 8.34596 + 0.287 \ln\left(\frac{200}{1200}\right) = 7.83173 \text{ kJ/kg K}$$

Interpolate in A.7.1 $\Rightarrow$ $T_{e\,s} = 761.9$ K, $h_{e\,s} = 780.52$ kJ/kg

$$w_{T\,s} = h_i - h_{e\,s} = 1277.81 - 780.52 = 497.3 \text{ kJ/kg}$$

The actual turbine then has

$$w_{T\,ac} = \eta_T w_{T\,s} = 0.87 \times 497.3 = 432.65 \text{ kJ/kg} = h_i - h_{e\,ac}$$

$$h_{e\,ac} = h_i - w_{T\,ac} = 1277.81 - 432.65 = 845.16 \text{ kJ/kg}$$

Interpolate in A.7.1 $\Rightarrow$ $T_{e\,ac} =$ **820.8 K**

If constant specific heats are used we get

Table A.5: $C_{Po} = 1.004$ kJ/kg K, $R = 0.287$ kJ/kg K, $k = 1.4$, then from Eq.6.23

$$T_{e\,s} = T_i (P_e/P_i)^{\frac{k-1}{k}} = 1200 \left(\frac{200}{1200}\right)^{0.286} = 719.2 \text{ K}$$

$$w_{T\,s} = C_{Po}(T_i - T_{e\,s}) = 1.004(1200 - 719.2) = 482.72 \text{ kJ/kg}$$

The actual turbine then has

$$w_{T\,ac} = \eta_T w_{T\,s} = 0.87 \times 482.72 = 419.97 \text{ kJ/kg} = C_{Po}(T_i - T_{e\,ac})$$

$$T_{e\,ac} = T_i - w_{T\,ac}/ C_{Po} = 1200 - 419.97/1.004 = \mathbf{781.7\ K}$$

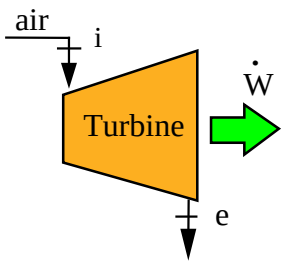
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.137

A gas turbine with air flowing in at 1200 kPa, 1200 K has an exit pressure of 200 kPa. Find the lowest possible exit temperature. Which efficiency does that correspond to?

Solution:

Look at the T-s diagram for the possible processes. We notice that the lowest exit T is for the isentropic process (the ideal turbine)



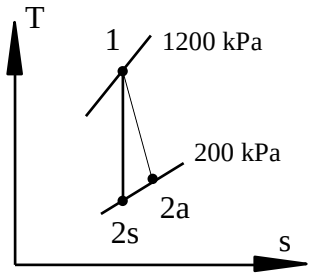


Table A.7: $h_i = 1277.8$ kJ/kg, $s^o_{Ti} = 8.34596$ kJ/kg K

The constant s process is written from Eq.6.19 as

$$\Rightarrow s^o_{Te} = s^o_{Ti} + R \ln\left(\frac{P_e}{P_i}\right) = 8.34596 + 0.287 \ln\left(\frac{200}{1200}\right) = 7.83173 \text{ kJ/kg K}$$

Interpolate in A.7.1 $\Rightarrow$ $T_{e\,s}$ = **761.9 K**

This is an efficiency of **100%**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

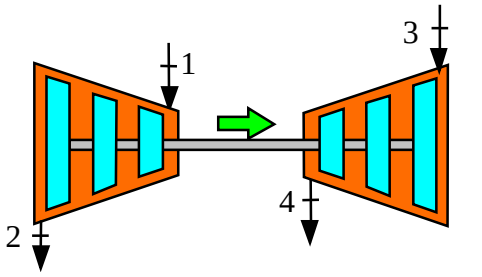
7.138

Repeat Problem 7.46 assuming the steam turbine and the air compressor each have an isentropic efficiency of 80%.

A certain industrial process requires a steady supply of saturated vapor steam at 200 kPa, at a rate of 0.5 kg/s. Also required is a steady supply of compressed air at 500 kPa, at a rate of 0.1 kg/s. Both are to be supplied by the process shown in Fig. P9.41. Steam is expanded in a turbine to supply the power needed to drive the air compressor, and the exhaust steam exits the turbine at the desired state. Air into the compressor is at the ambient conditions, 100 kPa, 20°C. Give the required steam inlet pressure and temperature, assuming that both the turbine and the compressor are reversible and adiabatic.

Solution:

C.V. Each device. Steady flow. Both adiabatic (q = 0) and actual devices ($s_{gen} > 0$) given by η_{sT} and η_{sc}.



Air Eq.6.23, $T_{4s} = T_3(P_4/P_3)^{\frac{k-1}{k}} = 293.2\left(\frac{500}{100}\right)^{0.286} = 464.6$ K

$$\dot{W}_{Cs} = \dot{m}_3(h_3 - h_{4s}) = 0.1 \text{ kg/s} \times 1.004 \text{ kJ/kgK } (293.2 - 464.6) \text{ K}$$
$$= -17.21 \text{ kW}$$

$$\dot{W}_{Cs} = \dot{m}_3(h_3 - h_4) = \dot{W}_{Cs}/\eta_{sc} = -17.2/0.80 = -21.5 \text{ kW}$$

Now the actual turbine must supply the actual compressor work. The actual state 2 is given so we must work backwards to state 1.

$$\dot{W}_T = +21.5 \text{ kW} = \dot{m}_1(h_1 - h_2) = 0.5(h_1 - 2706.6)$$
$$\Rightarrow \quad h_1 = 2749.6 \text{ kJ/kg}$$

Also, $\eta_{sT} = 0.80 = (h_1 - h_2)/(h_1 - h_{2s}) = 43/(2749.6 - h_{2s})$

$$\Rightarrow h_{2s} = 2695.8 \text{ kJ/kg}$$

$2695.8 = 504.7 + x_{2s}(2706.6 - 504.7) \quad \Rightarrow \quad x_{2s} = 0.9951$

$s_{2s} = 1.5301 + 0.9951(7.1271 - 1.5301) = 7.0996$ kJ/kg K

$(s_1 = s_{2s}, h_1) \rightarrow P_1 = \mathbf{269\ kPa}, \quad T_1 = \mathbf{143.5°C}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.139

Liquid water enters a pump at 15°C, 100 kPa, and exits at a pressure of 5 MPa. If the isentropic efficiency of the pump is 75%, determine the enthalpy (steam table reference) of the water at the pump exit.

Solution:

CV: pump $\dot{Q}_{CV} \approx 0$, $\Delta KE \approx 0$, $\Delta PE \approx 0$

2nd law, reversible (ideal) process: $s_{es} = s_i \Rightarrow$

Eq.7.15 for work term.

$$w_s = -\int_i^{es} vdP \approx -v_i(P_e - P_i) = -0.001001 \text{ m}^3/\text{kg } (5000 - 100) \text{ kPa}$$

$$= -4.905 \text{ kJ/kg}$$

Real process Eq.7.28: $w = w_s/\eta_s = -4.905/0.75 = -6.54$ kJ/kg

Energy Eq.4.13: $h_e = h_i - w = 62.99 + 6.54 =$ **69.53 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.140

Ammonia is brought from saturated vapor at 300 kPa to 1400 kPa, 140^{o}C in a steady flow adiabatic compressor. Find the compressor specific work, entropy generation and its isentropic efficiency.

C.V. Actual Compressor, assume adiabatic and neglect kinetic energies.

Energy Eq.4.13: $w_C = h_i - h_e$

Entropy Eq.7.9: $s_e = s_i + s_{gen}$

States: 1: B.2.2 $h_i = 1431.7$ kJ/kg, $s_i = 5.4565$ kJ/kg-K

2: B.2.2 $h_e = 1752.8$ kJ/kg, $s_e = 5.7023$ kJ/kg-K

$$-w_C = h_e - h_i = 1752.8 - 1431.7 = 321.1 \text{ kJ/kg}$$

Ideal compressor. We find the exit state from (P,s).

State 2s: P_e, $s_{e\,s} = s_i = 5.4565$ kJ/kg-K ⇨ $h_{e\,s} = 1656.08$ kJ/kg

$$-w_{C\,s} = h_{2s} - h_i = 1656.08 - 1431.7 = 224.38 \text{ kJ/kg}$$

$$\eta_C = -w_{C\,s} / -w_C = \frac{224.38}{321.1} = \mathbf{0.699}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.141

Find the isentropic efficiency of the nozzle in example 4.4.

Solution:

C.V. adiabatic nozzle with known inlet state and velocity.

Inlet state: B.1.3 $h_i = 2850.1$ kJ/kg; $s_i = 6.9665$ kJ/kg K

Process ideal: adiabatic and reversible Eq.7.9 gives constant s

ideal exit, (150 kPa, s) ; $x_{es} = (6.9665 - 1.4335)/5.7897 = 0.9557$

$h_{es} = h_f + x_{es}\, h_{fg} = 2594.9$ kJ/kg

$\mathbf{V}_{es}^2/2 = h_i - h_{es} + \mathbf{V}_i^2/2 = 2850.1 - 2594.9 + (50^2)/2000 = 256.45$ kJ/kg

$\mathbf{V}_{es} = 716.2$ m/s

From Eq.7.30,

$$\eta_{noz.} = (\mathbf{V}_e^2/2)/(\mathbf{V}_{es}^2/2) = 180/256.45 = \mathbf{0.70}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.142

A centrifugal compressor takes in ambient air at 100 kPa, 17°C, and discharges it at 450 kPa. The compressor has an isentropic efficiency of 80%. What is your best estimate for the discharge temperature?

Solution:

C.V. Compressor. Assume adiabatic, no kinetic energy is important.

Energy Eq.4.13: $w = h_1 - h_2$

Entropy Eq.7.9: $s_2 = s_1 + s_{gen}$

We have two different cases, the ideal and the actual compressor.

We will solve using constant specific heat.

State 2 for the ideal, $s_{gen} = 0$ so $s_2 = s_1$ and it becomes:

Eq.8.23: $T_{2s} = T_1 \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 290\ (450 / 100)^{0.2857} = 445.7$ K

$w_s = h_1 - h_{2s} = C_p\ (T_1 - T_{2s}) = 1.004\ (290 - 445.7) = -156.3$ kJ/kg

The actual work from definition Eq.7.28 and then energy equation:

$w_{ac} = w_s/\eta = -156.3 / 0.8 = -195.4$ kJ/kg $= h_1 - h_2 = C_p(T_1 - T_2)$

$\Rightarrow \quad T_2 = T_1 - w_{ac} / C_p$

$= 290 + 195.4/1.004 =$ **484.6 K**

Solving using Table A.7.1 instead will give

State 1: Table A.7.1: $s^o_{T1} = 6.83521$ kJ/kg K

Now constant s for the ideal is done with Eq.6.19

$s^o_{T2s} = s^o_{T1} + R \ln(\frac{P_2}{P_1}) = 6.83521 + 0.287 \ln(\frac{450}{100}) = 7.26688$ kJ/kg K

From A.7.1: $T_{2s} = 442.1$ K and $h_{2s} = 446.795$ kJ/kg

$w_s = h_1 - h_{2s} = 290.43 - 446.795 = -156.4$ kJ/kg

The actual work from definition Eq.7.28 and then energy equation:

$w_{ac} = w_s/\eta = -156.4 / 0.8 = -195.5$ kJ/kg

$\Rightarrow \quad h_2 = 195.5 + 290.43 = 485.93$, Table A.7.1: $T_2 =$ **483 K**

The answer is very close to the previous one due to the modest T's.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.143

A refrigerator uses carbon dioxide that is brought from 1 MPa, -20°C to 6 MPa using 2 kW power input to the compressor with a flow rate of 0.02 kg/s. Find the compressor exit temperature and its isentropic efficiency.

C.V. Actual Compressor, assume adiabatic and neglect kinetic energies.

Energy Eq.4.13: $$-w_C = h_2 - h_1 = \frac{\dot{W}}{\dot{m}} = \frac{2\ \text{kW}}{0.02\ \text{kg/s}} = 100\ \text{kJ/kg}$$

Entropy Eq.7.9: $$s_2 = s_1 + s_{gen}$$

States: 1: B.3.2 $h_1 = 342.31$ kJ/kg, $s_1 = 1.4655$ kJ/kg-K

2: B.3.2 $h_2 = h_1 - w_C = 442.31$ kJ/kg ⇨ $T_2 = \mathbf{117.7^oC}$

Ideal compressor. We find the exit state from (P,s).

State 2s: P_2, $s_{2s} = s_1 = 1.4655$ kJ/kg-K ⇨ $h_{2s} = 437.55$ kJ/kg

$$-w_{C\,s} = h_{2s} - h_1 = 437.55 - 342.31 = 95.24\ \text{kJ/kg}$$

$$\eta_C = -w_{C\,s} / -w_C = \frac{95.24}{100} = \mathbf{0.952}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.144

The small turbine in Problem 7.33 was ideal. Assume instead the isentropic turbine efficiency is 88%. Find the actual specific turbine work and the entropy generated in the turbine.

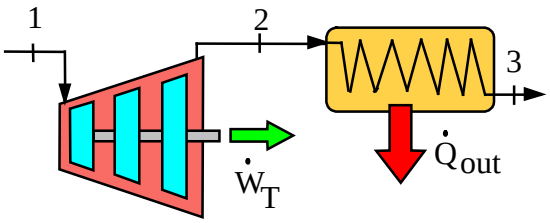
Solution:

Continuity Eq.4.11: (Steady)

$$\dot{m}_1 = \dot{m}_2 = \dot{m}_3 = \dot{m}$$

Turbine: Energy Eq.4.13:

$$w_T = h_1 - h_2$$



Entropy Eq.7.9: $s_2 = s_1 + s_{T\,gen}$

Inlet state: Table B.1.3 $h_1 = 3917.45$ kJ/kg, $s_1 = 7.9487$ kJ/kg K

Ideal turbine $s_{T\,gen} = 0$, $s_2 = s_1 = 7.9487 = s_{f2} + x\, s_{fg2}$

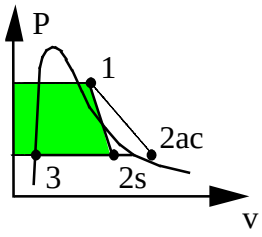
State 2: P = 10 kPa, $s_2 < s_g$ => saturated 2-phase in Table B.1.2

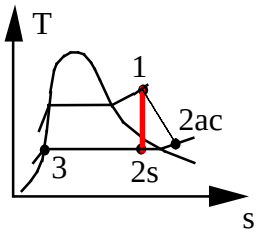
$\Rightarrow x_{2,s} = (s_1 - s_{f2})/s_{fg2} = (7.9487 - 0.6492)/7.501 = 0.9731$

$\Rightarrow h_{2,s} = h_{f2} + x \times h_{fg2} = 191.8 + 0.9731 \times 2392.8 = 2520.35$ kJ/kg

$w_{T,s} = h_1 - h_{2,s} = 1397.05$ kJ/kg

Explanation for the reversible work term is in sect. 7.3 Eq.7.14





$w_{T,AC} = \eta \times w_{T,s} =$ **1229.9 kJ/kg**

$= h_1 - h_{2,AC} \Rightarrow h_{2,AC} = h_1 - w_{T,AC} = 2687.5$ kJ/kg

$\Rightarrow T_{2,AC} = 100°C$, $s_{2,AC} = 8.4479$ kJ/kg-K

$s_{T\,gen} = s_{2,AC} - s_1 =$ **0.4992 kJ/kg K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.145

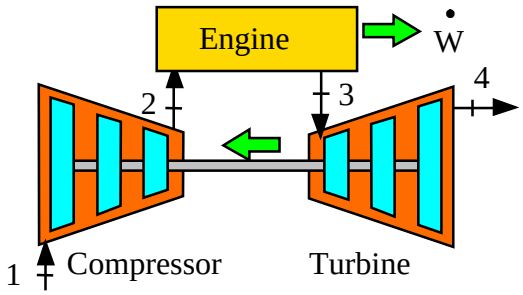
Redo Problem 7.41 assuming the compressor and turbine in the turbocharger both have isentropic efficiency of 85%.

CV: Turbine, Steady single inlet and exit flows,

Process: adiabatic: q = 0,
reversible: $s_{gen} = 0$

EnergyEq.4.13: $w_T = h_3 - h_4$,

Entropy Eq.7.8: $s_4 = s_3$



The property relation for ideal gas gives Eq.6.23, k from Table A.5

$$s_4 = s_3 \rightarrow T_4 = T_3(P_4/P_3)^{\frac{k-1}{k}} = 923.2\ \text{K}\left(\frac{100}{170}\right)^{0.286} = \mathbf{793.2\ K}$$

The energy equation is evaluated with specific heat from Table A.5

$$w_{T\,s} = h_3 - h_4 = C_{P0}(T_3 - T_4) = 1.004(923.2 - 793.2) = 130.5\ \text{kJ/kg}$$

The actual turbine : $w_{T\,ac} = \eta_T\, w_{T\,s} = 130.5 \times 0.85 = 110.9$ kJ/kg

$$\dot{W}_T = \dot{m} w_T = 110.9\ \text{kJ/kg} \times 0.1\ \text{kg/s} = \mathbf{11.09\ kW}$$

C.V. Compressor, steady 1 inlet and 1 exit, same flow rate as turbine.

Energy Eq.4.13: $-w_C = h_2 - h_1$,

Entropy Eq.7.9: $s_2 = s_1$

Express the energy equation for the shaft and actual compressor having the actual turbine power as input with the same mass flow rate so we get

$$-w_{C\,ac} = -w_{C\,s}/\eta_C = C_{P0}(T_{2\,s} - T_1)/\eta_C = w_{T\,ac} = 110.9\ \text{kJ/kg}$$

$$= 1.004(T_{2\,ac} - 303.2) = 1.004(T_{2\,s} - 303.2)/0.85$$

$$T_{2\,ac} = \mathbf{413.66\ K}, \quad T_{2\,s} = 397.09\ \text{K}$$

The property relation for $s_2 = s_1$ (only for ideal) is Eq.6.23 and inverted as

$$P_2 = P_1(T_{2\,s}/T_1)^{\frac{k}{k-1}} = 100\ \text{kPa}\left(\frac{397.09}{303.2}\right)^{3.5} = \mathbf{257\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.146

A pump receives water at 100 kPa, 15°C and a power input of 1.5 kW. The pump has an isentropic efficiency of 75% and it should flow 1.2 kg/s delivered at 30 m/s exit velocity. How high an exit pressure can the pump produce?

Solution:

CV Pump. We will assume the ideal and actual pumps have same exit pressure, then we can analyse the ideal pump.

Specific work: $w_{ac} = 1.5/1.2 = 1.25$ kJ/kg

Ideal work Eq.7.28: $w_s = \eta\, w_{ac} = 0.75 \times 1.25 = 0.9375$ kJ/kg

As the water is incompressible (liquid) we get

Energy Eq.7.14:

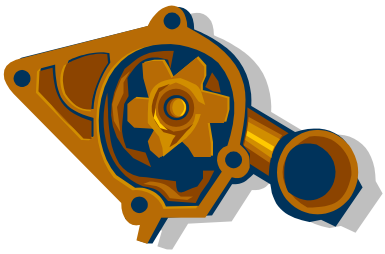
$$w_s = (P_e - P_i)v + \mathbf{V}^2_e/2 = (P_e - P_i)0.001001 + (30^2/2)/1000$$

$$= (P_e - P_i)0.001001 + 0.45$$

Solve for the pressure difference

$$P_e - P_i = (w_s - 0.45)/0.001001 = 487 \text{ kPa}$$

$$\mathbf{P_e = 587 \text{ kPa}}$$



Water pump from a car

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.147

A turbine receives air at 1500 K, 1000 kPa and expands it to 100 kPa. The turbine has an isentropic efficiency of 85%. Find the actual turbine exit air temperature and the specific entropy increase in the actual turbine using Table A.7.

Solution:

C.V. Turbine. steady single inlet and exit flow.

To analyze the actual turbine we must first do the ideal one (the reference).

Energy Eq.4.13: $w_T = h_1 - h_2$;

Entropy Eq.7.9: $s_2 = s_1 + s_{gen} = s_1$

Entropy change in Eq.6.19 and Table A.7.1:

$$s^o_{T2} = s^o_{T1} + R \ln(P_2/P_1) = 8.61208 + 0.287 \ln(100/1000) = 7.95124$$

Interpolate in A.7 => $T_{2s} = 849.2$, $h_{2s} = 876.56$ =>

$$w_T = 1635.8 - 876.56 = 759.24 \text{ kJ/kg}$$

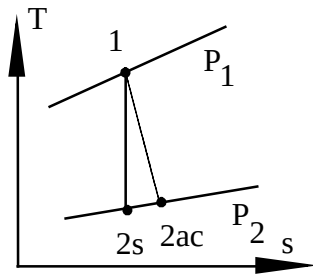
Now we can consider the actual turbine from Eq.7.27 and Eq.4.13:

$$w^T_{ac} = \eta_T w_T = 0.85 \times 759.24 = 645.35 = h_1 - h_{2ac}$$

$$\Rightarrow \quad h_{2ac} = h_1 - w^T_{ac} = 990.45 \quad \Rightarrow \quad \mathbf{T_{2ac} = 951\ K}$$

The entropy balance equation is solved for the generation term

$$s_{gen} = s_{2ac} - s_1 = 8.078 - 8.6121 - 0.287 \ln(100/1000) = \mathbf{0.1268\ kJ/kg\ K}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.148

Air enters an insulated turbine at 50°C, and exits the turbine at - 30°C, 100 kPa. The isentropic turbine efficiency is 70% and the inlet volumetric flow rate is 20 L/s. What is the turbine inlet pressure and the turbine power output?

Solution:

C.V.: Turbine, $\eta_S = 0.7$, Insulated

Air table A.5: $C_p = 1.004$ kJ/kg K, $R = 0.287$ kJ/kg K, $k = 1.4$

Inlet: $T_i = 50^oC$, $\dot{V}_i = 20$ L/s = 0.02 m^3/s ;

Exit (actual): $T_e = -30^oC$, $P_e = 100$ kPa

1st Law Steady state Eq.4.13: $q_T + h_i = h_e + w_T$; $q_T = 0$

Assume Constant Specific Heat

$w_T = h_i - h_e = C_p(T_i - T_e) = 80.3$ kJ/kg

$w_{Ts} = w/\eta = 114.7$ kJ/kg, $w_{Ts} = C_p(T_i - T_{es})$

Solve for $T_{es} = 208.9$ K

Isentropic Process Eq.6.23: $P_e = P_i (T_e / T_i)^{\frac{k}{k-1}}$ => $\mathbf{P_i = 461\ kPa}$

$\dot{m} = P_i\dot{V}/RT_i = (461\ \text{kPa} \times 0.02\ m^3/s) /(0.287\ \text{kJ/kg-K} \times 323.15\ \text{K})$

$= 0.099$ kg/s

$\dot{W}_T = \dot{m}w_T = 0.099\ \text{kg/s} \times 80.3\ \text{kJ/kg} = \mathbf{7.98\ kW}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.149

Carbon dioxide, CO_2, enters an adiabatic compressor at 100 kPa, 300 K, and exits at 1000 kPa, 520 K. Find the compressor efficiency and the entropy generation for the process.

Solution:

C.V. Ideal compressor. We will assume constant heat capacity.

Energy Eq.4.13: $w_c = h_1 - h_2$,

Entropy Eq.7.9: $s_2 = s_1 : \; T_{2s} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300\left(\frac{1000}{100}\right)^{0.2242} = 502.7$ K

$w_{cs} = C_p(T_1 - T_{2s}) = 0.842(300\text{-}502.7) = -170.67$ kJ/kg

C.V. Actual compressor

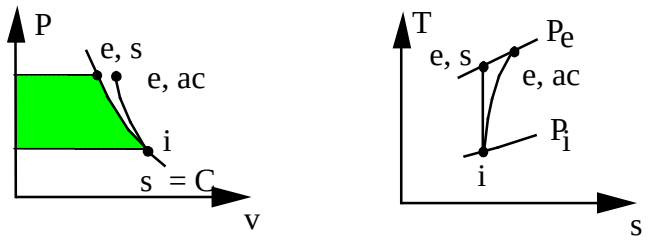
$w_{cac} = C_p(T_1 - T_{2ac}) = 0.842(300 - 520) = -185.2$ kJ/kg

$\eta_c = w_{cs}/w_{cac} = -170.67/(-185.2) =$ **0.92**

Use Eq.6.16 for the change in entropy

$s_{gen} = s_{2ac} - s_1 = C_p \ln (T_{2ac}/T_1) - R \ln (P_2/P_1)$

$= 0.842 \ln(520 / 300) - 0.1889 \ln(1000 / 100) =$ **0.028 kJ/kg K**



Constant heat capacity is not the best approximation. It would be more accurate to use Table A.8. Entropy change in Eq.6.19 and Table A.8:

$s^o_{T2} = s^o_{T1} + R \ln(P_2/P_1) = 4.8631 + 0.1889 \ln(1000/100) = 5.29806$

Interpolate in A.8 => $T_{2s} = 481$ K, $h_{2s} = 382.807$ kJ/kg =>

$-w_{cs} = 382.807 - 214.38 = 168.43$ kJ/kg; $-w_{cac} = 422.12 - 214.38 = 207.74$ kJ/kg

$\eta_c = w_{cs}/w_{cac} = -168.43/(-207.74) =$ **0.81**

$s_{gen} = s_{2ac} - s_1 = 5.3767 - 4.8631 - 0.1889 \ln(10) = 0.0786$ kJ/kgK

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.150

A small air turbine with an isentropic efficiency of 80% should produce 270 kJ/kg of work. The inlet temperature is 1000 K and it exhausts to the atmosphere. Find the required inlet pressure and the exhaust temperature.

Solution:

C.V. Turbine actual energy Eq.4.13:

$$w = h_i - h_{e,ac} = 270 \ \text{kJ/kg}$$

Table A.7: $h_i = 1046.22 \Rightarrow h_{e,ac} = 776.22$ kJ/kg, $\mathbf{T_e = 757.9\ K}$

C.V. Ideal turbine, Eq.7.27 and energy Eq.4.13:

$$w_s = w/\eta_s = 270/0.8 = 337.5 = h_i - h_{e,s} \Rightarrow h_{e,s} = 708.72 \ \text{kJ/kg}$$

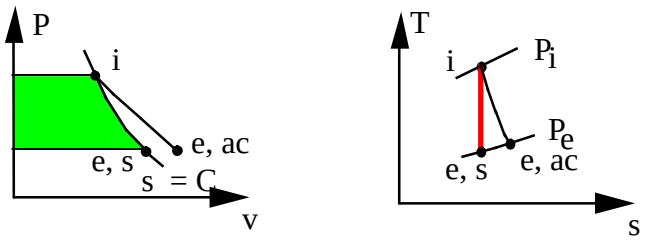
From Table A.7: $T_{e,s} = 695.5$ K

Entropy Eq.7.9: $s_i = s_{e,s}$ adiabatic and reversible

To relate the entropy to the pressure use Eq.6.19 inverted and standard entropy from Table A.7.1:

$$P_e/P_i = \exp[\ (s^o_{Te} - s^o_{Ti}\ ) / R\ ] = \exp[(7.733 - 8.13493)/0.287] = 0.2465$$

$$P_i = P_e / 0.2465 = 101.3/0.2465 = \mathbf{411\ kPa}$$



If constant heat capacity were used

$$T_e = T_i - w/C_p = 1000 - 270/1.004 = 731 \ \text{K}$$

C.V. Ideal turbine, Eq.7.27 and energy Eq.4.13:

$$w_s = w/\eta_s = 270/0.8 = 337.5 \ \text{kJ/kg} = h_i - h_{e,s} = C_p(T_i - T_{e,s})$$

$$T_{e,s} = T_i - w_s/C_p = 1000 - 337.5/1.004 = 663.8 \ \text{K}$$

Eq.7.9 (adibatic and reversible) gives constant s and relation is Eq.6.23

$$P_e/P_i = (T_e/T_i)^{k/(k-1)} \Rightarrow P_i = 101.3\ (1000/663.8)^{3.5} = 425 \ \text{kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.151

A compressor in an industrial air-conditioner compresses ammonia from a state of saturated vapor at 200 kPa to a pressure 800 kPa. At the exit, the temperature is measured to be 100°C and the mass flow rate is 0.5 kg/s. What is the required motor size for this compressor and what is its isentropic efficiency?

C.V. Compressor. Assume adiabatic and neglect kinetic energies.

Energy Eq.4.13: $w = h_1 - h_2$

Entropy Eq.7.9: $s_2 = s_1 + s_{gen}$

We have two different cases, the ideal and the actual compressor.

States: 1: B.2.2: $h_1 = 1419.6$ kJ/kg, $v_1 = 0.5946$ m^3/kg, $s_1 = 5.5979$ kJ/kg K

2ac: B.2.3 $h_{2,AC} = 1670.6$ kJ/kg, $v_{2,AC} = 0.21949$ m^3/kg

2s: B.2.3 (P, $s = s_1$) $h_{2,s} = 1613.7$ kJ/kg, $T_{2,s} = 76.6$°C

ACTUAL:

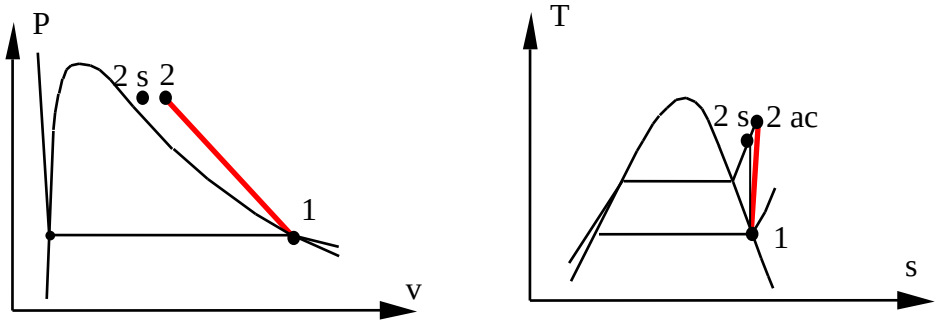
$$-w_{C,AC} = h_{2,AC} - h_1 = 1670.6 - 1419.6 = 251 \text{ kJ/kg}$$

$$\dot{W}_{in} = \dot{m}\,(-w_{C,AC}) = 0.5 \text{ kg/s} \times 251 \text{ kJ/kg} = \mathbf{125.5\ kW}$$

IDEAL:

$$-w_{c,s} = h_{2,s} - h_1 = 1613.7 - 1419.6 = 194.1 \text{ kJ/kg}$$

Definition Eq.7.28: $\eta_c = w_{c,s}/w_{c,AC} = \mathbf{0.77}$

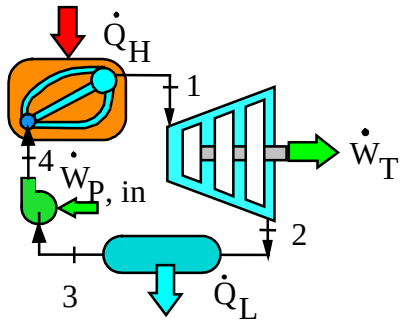


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.152

Repeat Problem 7.48 assuming the turbine and the pump each have an isentropic efficiency of 85%.

Solution:



$P_1 = P_4 = 20$ MPa
$T_1 = 700$ °C
$P_2 = P_3 = 20$ kPa
$T_3 = 40$ °C
$\eta_P = \eta_T = 85\%$

a) State 1: (P, T) Table B.1.3 $h_1 = 3809.1$ kJ/kg, $s_1 = 6.7993$ kJ/kg K

C.V. Turbine. First we do the ideal, then the actual.

Entropy Eq.7.9: $s_2 = s_1 = 6.7993$ kJ/kg K

Table B.1.2 $s_2 = 0.8319 + x_2 \times 7.0766$ => $x_2 = 0.8433$

$h_{2\,s} = 251.4 + 0.8433 \times 2358.33 = 2240.1$ kJ/kg

Energy Eq.4.13: $w_{T\,s} = h_1 - h_{2\,s} = 1569$ kJ/kg

$w_{T\,AC} = \eta_T w_{T\,s} = \mathbf{1333.65} = h_1 - h_{2\,AC}$

$h_{2\,AC} = h_1 - w_{T\,AC} = 2475.45$ kJ/kg;

$\mathbf{x_{2,AC}} = (2475.45 - 251.4)/2358.3 = \mathbf{0.943}$, $\mathbf{T_{2,AC} = 60.06°C}$

b)

State 3: (P, T) Compressed liquid, take sat. liq. Table B.1.1

$h_3 = 167.54$ kJ/kg, $v_3 = 0.001008$ m^3/kg

$w_{P\,s} = -v_3(P_4 - P_3) = -0.001008(20000 - 20) = -20.1$ kJ/kg

$-w_{P,AC} = -w_{P,s}/\eta_P = 20.1/0.85 = \mathbf{23.7} = h_{4,AC} - h_3$

$h_{4,AC} = \mathbf{191.2}$ $T_{4,AC} \cong 45.7°C$

c) The heat transfer in the boiler is from energy Eq.4.13

$q_{boiler} = h_1 - h_4 = 3809.1 - 191.2 = 3617.9$ kJ/kg

$w_{net} = 1333.65 - 23.7 = \mathbf{1310\ kJ/kg}$

$$\eta_{TH} = w_{net}/q_{boiler} = \frac{1310}{3617.9} = \mathbf{0.362}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.153

Assume an actual compressor has the same exit pressure and specific heat transfer as the ideal isothermal compressor in Problem 7.27 with an isothermal efficiency of 80%. Find the specific work and exit temperature for the actual compressor.

Solution:

C.V. Compressor. Steady, single inlet and single exit flows.

Energy Eq.4.13: $h_i + q = w + h_e$;

Entropy Eq.7.9: $s_i + q/T = s_e$

Inlet state: Table B.5.2, $h_i = 403.4$ kJ/kg, $s_i = 1.8281$ kJ/kg K

Exit state: Table B.5.1, $h_e = 398.36$ kJ/kg, $s_e = 1.7262$ kJ/kg K

$q = T(s_e - s_i) = 273.15(1.7262 - 1.8281) = -27.83$ kJ/kg

$w = 403.4 + (-27.83) - 398.36 = -22.8$ kJ/kg

From Eq.7.29 for a cooled compressor

$$w_{ac} = w_T/\eta = -22.8/0.8 = \mathbf{28.5\ kJ/kg}$$

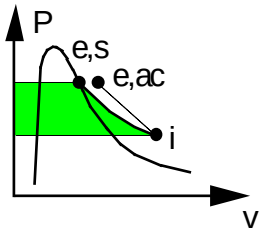
Now the energy equation gives

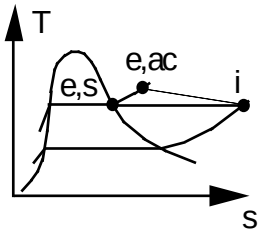
$$h_e = h_i + q - w_{ac} = 403.4 + (-27.83) + 28.5 = 404.07$$

$T_{e\,ac} \approx \mathbf{6°C}$ $\qquad$ $P_e = 294$ kPa

Explanation for the reversible work term is in Sect. 7.3

Eqs. 7.13 and 7.14





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.154

A nozzle in a high pressure liquid water sprayer has an area of 0.5 cm^2. It receives water at 350 kPa, 20°C and the exit pressure is 100 kPa. Neglect the inlet kinetic energy and assume a nozzle isentropic efficiency of 85%. Find the ideal nozzle exit velocity and the actual nozzle mass flow rate.

Solution:

C.V. Nozzle. Liquid water is incompressible v ≈ constant, no work, no heat transfer => Bernoulli Eq.7.17

$$\frac{1}{2}\mathbf{V}_{ex}^2 - 0 = v(P_i - P_e) = 0.001002\ (\ 350 - 100) = 0.2505\ \text{kJ/kg}$$

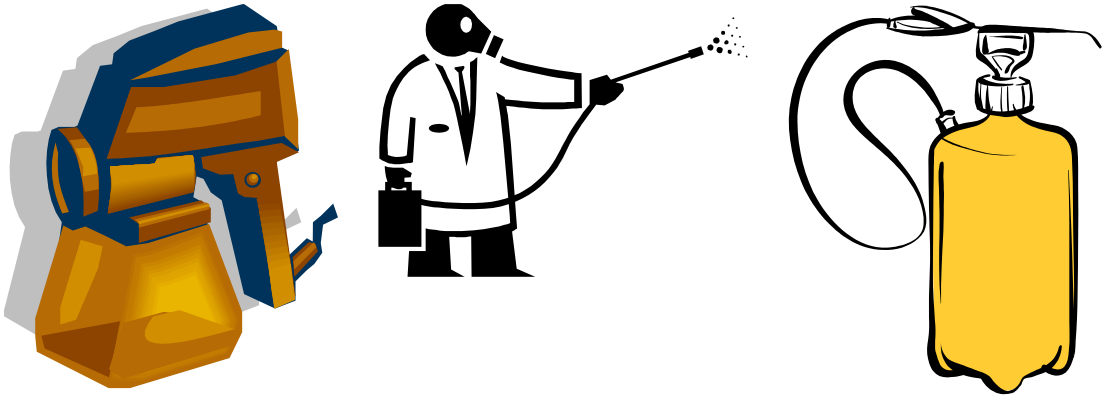
$$\mathbf{V}_{ex} = \sqrt{2 \times 0.2505 \times 1000\ \text{J/kg}} = \mathbf{22.38\ m\ s^{-1}}$$

This was the ideal nozzle now we can do the actual nozzle, Eq. 7.30

$$\frac{1}{2}\mathbf{V}_{ex\ ac}^2 = \eta \frac{1}{2}\mathbf{V}_{ex}^2 = 0.85 \times 0.2505 = 0.2129\ \text{kJ/kg}$$

$$\mathbf{V}_{ex\ ac} = \sqrt{2 \times 0.2129 \times 1000\ \text{J/kg}} = 20.63\ \text{m s}^{-1}$$

$$\dot{m} = \rho A \mathbf{V}_{ex\ ac} = A\mathbf{V}_{ex\ ac}/v = 0.5 \times 10^{-4} \times 20.63 / 0.001002 = \mathbf{1.03\ kg/s}$$



These are examples of relatively low pressure spray systems.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.155

Air flows into an insulated nozzle at 1 MPa, 1200 K with 15 m/s and mass flow rate of 2 kg/s. It expands to 650 kPa and exit temperature is 1100 K. Find the exit velocity, and the nozzle efficiency.

Solution:

C.V. Nozzle. Steady 1 inlet and 1 exit flows, no heat transfer, no work.

Energy Eq.4.13: $h_i + (1/2)\mathbf{V}_i^2 = h_e + (1/2)\mathbf{V}_e^2$

Entropy Eq.7.9: $s_i + s_{gen} = s_e$

Ideal nozzle $s_{gen} = 0$ and assume same exit pressure as actual nozzle. Instead of using the standard entropy from Table A.7 and Eq.6.19 let us use a constant heat capacity at the average T and Eq.6.23. First from A.7.1

$$C_{p\ 1150} = \frac{1277.81 - 1161.18}{1200 - 1100} = 1.166 \text{ kJ/kg K};$$

$$C_v = C_{p\ 1150} - R = 1.166 - 0.287 = 0.8793, \quad k = C_{p\ 1150}/C_v = 1.326$$

Notice how they differ from Table A.5 values.

$$T_{e\,s} = T_i\,(P_e/P_i)^{\frac{k-1}{k}} = 1200\left(\frac{650}{1000}\right)^{0.24585} = 1079.4 \text{ K}$$

$$\tfrac{1}{2}\mathbf{V}_{e\,s}^2 = \tfrac{1}{2}\mathbf{V}_i^2 + C(T_i - T_{e\,s}) = \tfrac{1}{2}\times 15^2 + 1.166(1200 - 1079.4)\times 1000$$

$$= 112.5 + 140619.6 = 140732 \text{ J/kg} \quad \Rightarrow \quad \mathbf{V}_{e\,s} = 530.5 \text{ m/s}$$

Actual nozzle with given exit temperature

$$\tfrac{1}{2}\mathbf{V}_{e\,ac}^2 = \tfrac{1}{2}\mathbf{V}_i^2 + h_i - h_{e\,ac} = 112.5 + 1.166(1200 - 1100)\times 1000$$

$$= 116712.5 \text{ J/kg}$$

$$\Rightarrow \quad \mathbf{V}_{e\,ac} = \mathbf{483 \text{ m/s}}$$

$$\eta_{noz} = (\tfrac{1}{2}\mathbf{V}_{e\,ac}^2 - \tfrac{1}{2}\mathbf{V}_i^2)/(\tfrac{1}{2}\mathbf{V}_{e\,s}^2 - \tfrac{1}{2}\mathbf{V}_i^2) =$$

$$= (h_i - h_{e,\,AC})/(h_i - h_{e,\,s}) = \frac{116600}{140619.6} = \mathbf{0.829}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.156

A nozzle is required to produce a flow of air at 200 m/s at 20°C, 100 kPa. It is estimated that the nozzle has an isentropic efficiency of 92%. What nozzle inlet pressure and temperature is required assuming the inlet kinetic energy is negligible?

Solution:

C.V. Air nozzle: P_e, T_e(real), V_e(real), η_s(real)

For the real process: $h_i = h_e + \mathbf{V}_e^2/2$ or

$T_i = T_e + \mathbf{V}_e^2/2C_{P0} = 293.2 + 200^2/2 \times 1000 \times 1.004 =$ **313.1 K**

For the ideal process, from Eq.7.30:

$\mathbf{V}_{es}^2/2 = \mathbf{V}_e^2/2\eta_s = 200^2/2 \times 1000 \times 0.92 = 21.74$ kJ/kg

and $h_i = h_{es} + (\mathbf{V}_{es}^2/2)$

$T_{es} = T_i - \mathbf{V}_{es}^2/(2C_{P0}) = 313.1 - 21.74/1.004 = 291.4$ K

The constant s relation in Eq.6.23 gives

$$\Rightarrow \quad P_i = P_e\,(T_i/T_{es})^{\frac{k}{k-1}} = 100\left(\frac{313.1}{291.4}\right)^{3.50} = \mathbf{128.6\ kPa}$$

7.157

A water-cooled air compressor takes air in at 20°C, 90 kPa and compresses it to 500 kPa. The isothermal efficiency is 88% and the actual compressor has the same heat transfer as the ideal one. Find the specific compressor work and the exit temperature.

Solution:

Ideal isothermal compressor exit 500 kPa, 20°C

Reversible process: $dq = T\,ds \quad \Rightarrow \quad q = T(s_e - s_i)$

$$q = T(s_e - s_i) = T[s^o_{Te} - s^o_{T1} - R \ln(P_e / P_i)]$$

$$= - RT \ln (P_e / P_i) = - 0.287 \times 293.15 \ln (500/90) = - 144.3 \text{ kJ/kg}$$

As same temperature for the ideal compressor $h_e = h_i \Rightarrow$

$$w = q = -144.3 \text{ kJ/kg} \quad \Rightarrow \quad w_{ac} = w/\eta = \mathbf{- 163.98\ kJ/kg}, \quad q_{ac} = q$$

Now for the actual compressor energy equation becomes

$$q_{ac} + h_i = h_{e\,ac} + w_{ac} \Rightarrow$$

$$h_{e\,ac} - h_i = q_{ac} - w_{ac} = - 144.3 - (-163.98) = 19.7 \text{ kJ/kg} \approx C_p (T_{e\,ac} - T_i)$$

$$T_{e\,ac} = T_i + 19.7/1.004 = \mathbf{39.6°C}$$

7.158

A flow of saturated liquid R-410A at 200 kPa in an evaporator is brought to a state of superheated vapor at 200 kPa, 20^{o}C. Assume the process is reversible find the specific heat transfer and specific work.

C.V. Evaporator. From the device we know that potential and kinetic energies are not important (see chapter 6).

Since the pressure is constant and the process is reversible from Eq.7.14

$$w = -\int v dP + 0 + 0 - 0 = \mathbf{0}$$

From energy equation

$$h_i + q = w + h_e = h_e; \qquad q = h_e - h_i$$

State i: $h_i = 4.18$ kJ/kg, State e: $h_e = 311.78$ kJ/kg

$$q = h_e - h_i = 311.78 - 4.18 = \mathbf{307.6\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.159

A flow of R-410A at 2000 kPa, 40^{o}C in an isothermal expander is brought to a state of 1000 kPa in a reversible process. Find the specific heat transfer and work.

C.V. Expander. Steady reversible, single inlet and exit flow. Some q and w

Energy Eq.4.13: $h_i + q = w + h_e$;

Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e$

Process: T = constant so $\int dq/T = q/T$ and reversible $s_{gen} = 0$

State i: h_i = 295.49 kJ/kg, s_i = 1.0099 kJ/kg-K

State e: h_e = 316.05 kJ/kg, s_e = 1.1409 kJ/kg-K

From entropy equation

$$q = T (s_e - s_i) = 313.15 \text{ K } (1.1409 - 1.0099) \text{ kJ/kg-K} = \mathbf{41.023 \text{ kJ/kg}}$$

From the energy equation

$$w = h_i - h_e + q = 295.49 - 316.05 + 41.023 = \mathbf{330.46 \text{ kJ/kg}}$$

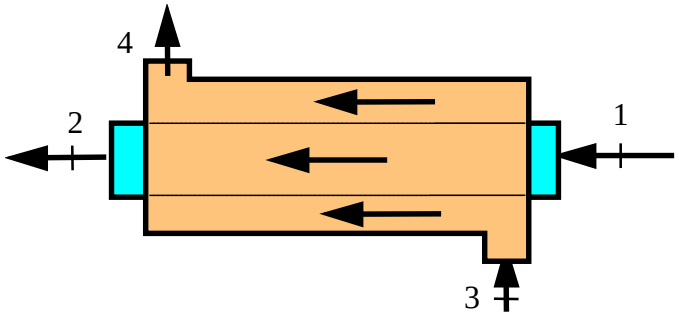
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.160

A coflowing heat exchanger has one line with 2 kg/s saturated water vapor at 100 kPa entering. The other line is 1 kg/s air at 200 kPa, 1200 K. The heat exchanger is very long so the two flows exit at the same temperature. Find the exit temperature by trial and error. Calculate the rate of entropy generation.

Solution:

C.V. Heat exchanger, steady 2 flows in and two flows out.
No W, no external Q



Flows: $\dot{m}_1 = \dot{m}_2 = \dot{m}_{H_2O}$; $\dot{m}_3 = \dot{m}_4 = \dot{m}_{air}$

Energy: $\dot{m}_{H_2O}\,(h_2 - h_1) = \dot{m}_{air}\,(h_3 - h_4)$

State 1: Table B.1.2 $h_1 = 2675.5$ kJ/kg State 2: 100 kPa, T_2

State 3: Table A.7 $h_3 = 1277.8$ kJ/kg, State 4: 200 kPa, T_2

Only one unknown T_2 and one equation the energy equation:

$2(h_2 - 2675.5) = 1(1277.8 - h_4)$ => $1\ \text{kg/s} \times (2h_2 + h_4) = 6628.8$ kW

At 500 K: $h_2 = 2902.0$, $h_4 = 503.36$ => LHS = 6307 too small

At 700 K: $h_2 = 3334.8$, $h_4 = 713.56$ => LHS = 7383 too large

Linear interpolation $T_2 = 560$ K, $h_2 = 3048.3$, $h_4 = 565.47$ => LHS = 6662

Final states are with **$T_2 = 554.4$ K = 281 °C**

H2O: Table B.1.3, $h_2 = 3036.8$ kJ/kg, $s_2 = 8.1473$, $s_1 = 7.3593$ kJ/kg K

AIR: Table A.7, $h_4 = 559.65$ kJ/kg, $s_{T4} = 7.4936$, $s_{T3} = 8.3460$ kJ/kg K

The entropy balance equation, Eq.7.7, is solved for the generation term:

$$\dot{S}_{gen} = \dot{m}_{H_2O}\,(s_2 - s_1) + \dot{m}_{air}\,(s_4 - s_3)$$

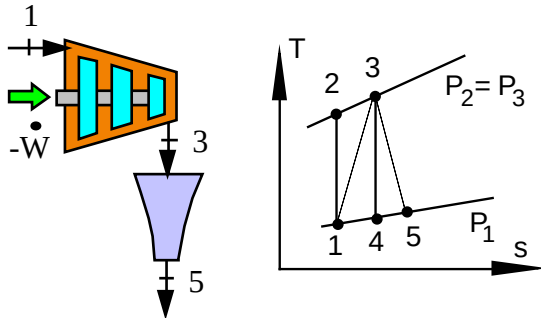
$$= 2(8.1473 - 7.3593) + 1\,(7.4936 - 8.3460) = \mathbf{0.724\ kW/K}$$

No pressure correction is needed as the air pressure for 4 and 3 is the same.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.161

Air at 100 kPa, 17°C is compressed to 400 kPa after which it is expanded through a nozzle back to the atmosphere. The compressor and the nozzle both have an isentropic efficiency of 90% and are adiabatic. The kinetic energy into and out of the compressor can be neglected. Find the compressor work and its exit temperature and find the nozzle exit velocity.



C.V. Ideal compressor, inlet: 1 exit: 2

Adiabatic : q = 0.
Reversible: $s_{gen} = 0$

Energy Eq.4.13: $h_1 + 0 = w_C + h_2$;

Entropy Eq.7.8: $s_1 + 0/T + 0 = s_2$

$$- w_{Cs} = h_2 - h_1 , \quad s_2 = s_1$$

Properties use air Table A.5: $C_{Po} = 1.004 \frac{kJ}{kg\ K}$, $R = 0.287 \frac{kJ}{kg\ K}$, $k = 1.4$,

Process gives constant s (isentropic) which with constant C_{Po} gives Eq.6.23

$$\Rightarrow \quad T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 290\ (400/100)^{0.2857} = \mathbf{430.9\ K}$$

$$\Rightarrow \quad -w_{Cs} = C_{Po}(T_2 - T_1) = 1.004\ (430.9 - 290) = \mathbf{141.46\ kJ/kg}$$

The ideal nozzle then expands back down to state 1 (constant s). The actual compressor discharges at state 3 however, so we have:

$$w_C = w_{Cs}/\eta_C = \mathbf{-157.18} \quad \Rightarrow \quad T_3 = T_1 - w_C/C_p = \mathbf{446.6\ K}$$

Nozzle receives air at 3 and exhausts at 5. We must do the ideal (exit at 4) first.

$$s_4 = s_3 \ \Rightarrow \text{ Eq.6.23:} \quad T_4 = T_3\ (P_4/P_3)^{\frac{k-1}{k}} = 300.5\ K$$

$$\tfrac{1}{2}\mathbf{V}_s^2 = C_p(T_3 - T_4) = 146.68 \ \Rightarrow \ \tfrac{1}{2}\mathbf{V}_{ac}^2 = 132\ kJ/kg \ \Rightarrow V_{ac} = \mathbf{513.8\ m/s}$$

If we need it, the actual nozzle exit (5) can be found:

$$T_5 = T_3 - \mathbf{V}_{ac}^2/2C_p = 315\ K$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.162

A vortex tube has an air inlet flow at 20°C, 200 kPa and two exit flows of 100 kPa, one at 0°C and the other at 40°C. The tube has no external heat transfer and no work and all the flows are steady and have negligible kinetic energy. Find the fraction of the inlet flow that comes out at 0°C. Is this setup possible?

Solution:

C.V. The vortex tube. Steady, single inlet and two exit flows. No q or w.

Continuity Eq.: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$; Energy: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3$

Entropy: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3$

States all given by temperature and pressure. Use constant heat capacity to evaluate changes in h and s. Solve for $x = \dot{m}_2/\dot{m}_1$ from the energy equation

$\dot{m}_3/\dot{m}_1 = 1 - x$; $h_1 = x\, h_2 + (1-x)\, h_3$

$\Rightarrow$ $x = (h_1 - h_3)/(h_2 - h_3) = (T_1 - T_3)/(T_2 - T_3) = (20-40)/(0-40) = 0.5$

Evaluate the entropy generation (assuming constant specific heat)

$$\dot{S}_{gen}/\dot{m}_1 = x\, s_2 + (1-x)s_3 - s_1 = 0.5(s_2 - s_1) + 0.5(s_3 - s_1)$$

$$= 0.5\,[C_p \ln(T_2 / T_1) - R \ln(P_2 / P_1)] + 0.5[C_p \ln(T_3 / T_1) - R \ln(P_3 / P_1)]$$

$$= 0.5\left[1.004 \ln\left(\frac{273.15}{293.15}\right) - 0.287 \ln\left(\frac{100}{200}\right)\right]$$

$$+ 0.5\left[1.004 \ln\left(\frac{313.15}{293.15}\right) - 0.287 \ln\left(\frac{100}{200}\right)\right]$$

= **0.1966 kJ/kg K > 0** **So this is possible**.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.163

Air enters an insulated turbine at 50°C, and exits the turbine at - 30°C, 100 kPa. The isentropic turbine efficiency is 70% and the inlet volumetric flow rate is 20 L/s. What is the turbine inlet pressure and the turbine power output?

C.V.: Turbine, $\eta_S = 0.7$, Insulated

Air: $C_p = 1.004$ kJ/kg-K, $R = 0.287$ kJ/kg-K, $k = 1.4$

Inlet: $T_i = 50^oC$, $\dot{V}_i = 20$ L/s = 0.02 m^3/s

Exit: $T_e = -30^oC$, $P_e = 100$ kPa

a) Energy Eq., steady flow: $q + h_i = h_e + w_T$; $q = 0$

Assume Constant Specific Heat

$w_T = h_i - h_e = C_p(T_i - T_e) = 80.3$ kJ/kg

$w_{Ts} = w/\eta = 114.7$ kJ/kg, $w_{Ts} = C_p(T_i - T_{es})$

Solve for $T_{es} = 208.9$ K

Isentropic Process: $P_e = P_i (T_e / T_i)^{\frac{k}{k-1}}$ => **P_i = 461 kPa**

b) $\dot{W}_T = \dot{m} w_T$; $\dot{m} = P\dot{V}/RT = 0.099$ kg/s => $\dot{W}_T$ = **7.98 kW**

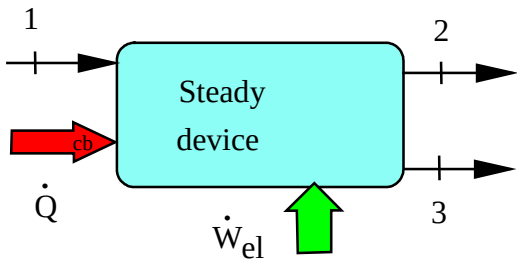
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.164

A stream of ammonia enters a steady flow device at 100 kPa, 50°C, at the rate of 1 kg/s. Two streams exit the device at equal mass flow rates; one is at 200 kPa, 50°C, and the other as saturated liquid at 10°C. It is claimed that the device operates in a room at 25°C on an electrical power input of 250 kW. Is this possible?

Solution:

Control volume: Steady device out to ambient 25°C.



Energy Eq.4.10: $\dot{m}_1 h_1 + \dot{Q} + \dot{W}_{el} = \dot{m}_2 h_2 + \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{Q}/T_{room} + \dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3$

State 1: Table B.2.2, $h_1 = 1581.2$ kJ/kg, $s_1 = 6.4943$ kJ/kg K

State 2: Table B.2.2 $h_2 = 1576.6$ kJ/kg, $s_2 = 6.1453$ kJ/kg K

State 3: Table B.2.1 $h_3 = 226.97$ kJ/kg, $s_3 = 0.8779$ kJ/kg K

From the energy equation

$$\dot{Q} = 0.5 \times 1576.6 + 0.5 \times 226.97 - 1 \times 1581.2 - 250 = -929.4 \text{ kW}$$

From the entropy equation

$$\dot{S}_{gen} = 0.5 \times 6.1453 + 0.5 \times 0.8779 - 1 \times 6.4943 - (-929.4)/298.15$$
$$= 0.1345 \text{ kW/K} > 0$$

since $\dot{S}_{gen} > 0$ this is possible

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.165

In a heat-powered refrigerator, a turbine is used to drive the compressor using the same working fluid. Consider the combination shown in Fig. P9.157 where the turbine produces just enough power to drive the compressor and the two exit flows are mixed together. List any assumptions made and find the ratio of mass flow rates $\dot{m}_3/\dot{m}_1$ and T_5 (x_5 if in two-phase region) if the turbine and the compressor are reversible and adiabatic

Solution:

CV: compressor

$s_{2S} = s_1 = 1.0779$ kJ/kg K $\rightarrow$ $h_{2S} = 317.43$ kJ/kg

$w_{SC} = h_1 - h_{2S} = 271.89 - 317.43 = -45.54$ kJ/kg

CV: turbine

$s_{4S} = s_3 = 1.0850$ kJ/kgK and P_{4S} $\Rightarrow$ $h_{4S} = 319.72$ kJ/kg

$w_{ST} = h_3 - h_{4S} = 341.29 - 319.72 = 21.57$ kJ/kg

As $\dot{w}_{TURB} = -\dot{w}_{COMP}$, $\dot{m}_3/\dot{m}_1 = -\dfrac{w_{SC}}{w_{ST}} = \dfrac{45.54}{21.57} = \mathbf{2.111}$

CV: mixing portion

$\dot{m}_1 h_{2S} + \dot{m}_3 h_{4S} = (\dot{m}_1 + \dot{m}_3) h_5$

$1 \times 317.43 + 2.111 \times 319.72 = 3.111\ h_5$

$\Rightarrow h_5 = 318.984$ kJ/kg => $T_5 = \mathbf{58.7°C}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.166

A certain industrial process requires a steady 0.5 kg/s supply of compressed air at 500 kPa, at a maximum temperature of 30°C. This air is to be supplied by installing a compressor and aftercooler, see Fig. P9.46. Local ambient conditions are 100 kPa, 20°C. Using an isentropic compressor efficiency of 80%, determine the power required to drive the compressor and the rate of heat rejection in the aftercooler.

Air table A.5: R = 0.287 kJ/kg-K, C_p = 1.004 kJ/kg-K, k = 1.4

State 1: $T_1 = T_o = 20^oC$, $P_1 = P_o$ = 100 kPa, $\dot{m}$ = 0.5 kg/s

State 2: $P_2 = P_3$ = 500 kPa

State 3: $T_3 = 30^oC$, P_3 = 500 kPa

We have η_s = 80 % = $w_{Cs}/w_{C\,ac}$

Compressor: First do the ideal (Isentropic)

$$T_{2s} = T_1 (P_2/P_1)^{\frac{k-1}{k}} = 293.15 \ (500/100)^{0.2857} = 464.6 \text{ K}$$

Energy Eq.: $q_C + h_1 = h_2 + w_C$; $q_C = 0$, assume constant specific heat

$$w_{cs} = C_p(T_1 - T_{2s}) = 1.004\ (293.15 - 464.6) = -172.0 \text{ kJ/kg}$$

$\eta_s = w_{Cs}/w_{C\,ac}$, $w_{C\,ac} = w_{Cs}/\eta_s = -215$, $\dot{W}_C = \dot{m}w_C =$ **-107.5 kW**

$w_{C\,ac} = C_p (T_1 - T_2)$, solve for T_2 = 507.5 K

Aftercooler:

Energy Eq.: $q + h_2 = h_3 + w$; $w = 0$, assume constant specific heat

$$q = C_p (T_3 - T_2) = 1.004(303.15 - 507.5) = -205 \text{ kJ/kg},$$

$\dot{Q} = \dot{m}q =$ **-102.5 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.167

Carbon dioxide flows through a device entering at 300 K, 200 kPa and leaving at 500 K. The process is steady state polytropic with n = 3.8 and heat transfer comes from a 600 K source. Find the specific work, specific heat transfer and the specific entropy generation due to this process.

Solution:

C.V. Steady state device, single inlet and single exit flow.

Energy Eq.4.13: $h_i + q = h_e + w$ Neglect kinetic, potential energies

Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e$

Process Eq.6.28:

$$P_e = P_i (T_e/ T_i)^{\frac{n}{n-1}} = 200(500/300)^{\frac{3.8}{2.8}} = 400 \text{ kPa}$$

and the process leads to Eq.7.18 for the work term

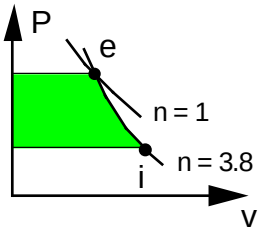
$$w = -\frac{n}{n-1} R (T_e - T_i) = -\frac{3.8}{2.8} \times 0.1889 \times (500 - 300) = \mathbf{-51.3\ kJ/kg}$$

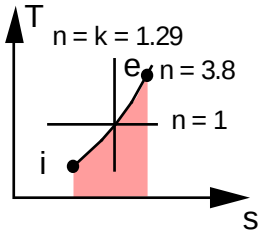
Energy equation gives

$$q = h_e - h_i + w = 401.52 - 214.38 - 51.3 = \mathbf{135.8\ kJ/kg}$$

Entropy equation gives (CV out to source)

$$s_{gen} = s_e - s_i - q/T_{source} = s^o_{Te} - s^o_{Ti} - R \ln(P_e / P_i) - q/T_{source}$$
$$= 5.3375 - 4.8631 - 0.1889 \ln (400/200) - (135.8/600)$$
$$= \mathbf{0.117\ kJ/kg\ K}$$





Notice:
dP > 0
so dw <0

ds > 0
so dq > 0

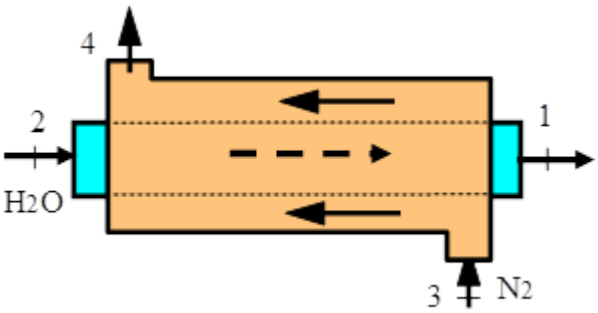
Notice process is externally irreversible, ΔT between source and CO_2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.168

A flow of nitrogen, 0.1 kg/s, comes out of a compressor stage at 500 kPa, 500 K and is now cooled to 310 K in a counterflowing intercooler by liquid water at 125 kPa, 15°C which leaves at 22°C. Find the flowrate of water and the total rate of entropy generation.

Solution:



A hydraulic motor driven compressor with intercooler in small pipe between the two stages.

Continuity eq.: $\dot{m}_1 = \dot{m}_2 = \dot{m}_{H2O}$; $\dot{m}_3 = \dot{m}_4 = \dot{m}_{N2}$

Energy eq.: $0 = \dot{m}_{N2}\,(h_3 - h_4) + \dot{m}_{H2O}\,(h_2 - h_1)$

Entropy Eq.7.7: $0 = \dot{m}_{N2}\,(s_3 - s_4) + \dot{m}_{H_2O}\,(s_2 - s_1) + \dot{S}_{gen}$

Due to the lower range of temperature we will use constant specific heats from A.5 and A.4 so the energy equation is approximated as

$$0 = \dot{m}_{H2O} C_{pH2O}\,(T_2 - T_1) + \dot{m}_{N2} C_p\,(T_3 - T_4)$$

Now solve for the water flow rate

$$\dot{m}_{H2O} = \dot{m}_{N2}\, C_{pN2}\,(T_3 - T_4) / [C_{pH2O}\,(T_1 - T_2)]$$

$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \times (500 - 310) \text{ K} / [4.18 \times (22 - 15) \text{ kJ/kg}]$$

$$= \mathbf{0.677 \text{ kg/s}}$$

$$\dot{S}_{gen} = \dot{m}_{N2}\,(s_4 - s_3) + \dot{m}_{H_2O}\,(s_1 - s_2)$$

$$= \dot{m}_{N2} C_P \ln (T_4/T_3) + \dot{m}_{H_2O} C_P \ln (T_1/T_2)$$

$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \ln \frac{310}{500} + 0.677 \text{ kg/s} \times 4.18 \text{ kJ/kgK} \ln \frac{295}{288}$$

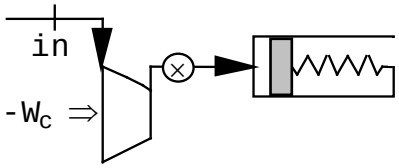
$$= -0.04981 + 0.06796 = \mathbf{0.0182 \text{ kW/K}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.169

An initially empty spring-loaded piston/cylinder requires 100 kPa to float the piston. A compressor with a line and valve now charges the cylinder with water to a final pressure of 1.4 MPa at which point the volume is 0.6 m^3, state 2. The inlet condition to the reversible adiabatic compressor is saturated vapor at 100 kPa. After charging the valve is closed and the water eventually cools to room temperature, 20°C, state 3. Find the final mass of water, the piston work from 1 to 2, the required compressor work, and the final pressure, P_3.

Solution:



Process 1→2: transient, adiabatic.
for C.V. compressor + cylinder
Assume process is reversible

Continuity: $m_2 - 0 = m_{in}$, Energy: $m_2u_2 - \emptyset = (m_{in}h_{in}) - W_c - {}_1W_2$

Entropy Eq.: $m_2s_2 - \emptyset = m_{in}s_{in} + 0 \quad \Rightarrow \quad s_2 = s_{in}$

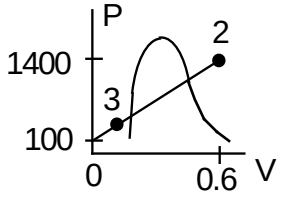
Inlet state: Table B.1.2, $h_{in} = 2675.5$ kJ/kg, $s_{in} = 7.3594$ kJ/kg K

$${}_1W_2 = \int PdV = \frac{1}{2}(P_{float} + P_2)(V_2 - \emptyset) = \frac{1}{2}(100+1400)0.6 = \mathbf{450\ kJ}$$

State 2: P_2 , $s_2 = s_{in}$ Table B.1.3 $\Rightarrow$ $v_2 = 0.2243$, $u_2 = 2984.4$ kJ/kg

$m_2 = V_2/v_2 = 0.6/0.2243 =$ **2.675 kg**

$W_c = m_{in}h_{in} - m_2u_2 - {}_1W_2 = 2.675 \times (2675.5 - 2984.4) - 450 =$ **-1276.3 kJ**



State 3 must be on line & 20°C
Assume 2-phase $\Rightarrow$ $P_3 = P_{sat}(20°C) = 2.339$ kPa
less than P_{float} so compressed liquid

Table B.1.1: $v_3 \cong v_f(20°C) = 0.001002 \quad \Rightarrow \quad V_3 = m_3v_3 = 0.00268\ m^3$

On line: $P_3 = 100 + (1400 - 100) \times 0.00268/0.6 =$ **105.8 kPa**

7.170

Consider the scheme shown in Fig. P7.170 for producing fresh water from salt water. The conditions are as shown in the figure. Assume that the properties of salt water are the same as for pure water, and that the pump is reversible and adiabatic.

a. Determine the ratio ($\dot{m}_7/\dot{m}_1$), the fraction of salt water purified.
b. Determine the input quantities, w_P and q_H.
c. Make a second law analysis of the overall system.

C.V. Flash evaporator: Steady flow, no external q, no work.

Energy Eq.: $\dot{m}_1 h_4 = (\dot{m}_1 - \dot{m}_7)h_5 + \dot{m}_7 h_6$

Table B.1.1 or $632.4 = \left(1 - (\dot{m}_7/\dot{m}_1)\right) 417.46 + (\dot{m}_7/\dot{m}_1)\, 2675.5$

$\Rightarrow \dot{m}_7/\dot{m}_1 = \mathbf{0.0952}$

C.V. Pump steady flow, incompressible liq.:

$w_P = -\int v dP \approx -v_1(P_2 - P_1) = -\,0.001001(700 - 100) = \mathbf{-0.6\ kJ/kg}$

$h_2 = h_1 - w_P = 62.99 + 0.6 = 63.6$ kJ/kg

C.V. Heat exchanger: $h_2 + (\dot{m}_7/\dot{m}_1)h_6 = h_3 + (\dot{m}_7/\dot{m}_1)h_7$

$63.6 + 0.0952 \times 2675.5 = h_3 + 0.0952 \times 146.68 \Rightarrow h_3 = 304.3$ kJ/kg

C.V. Heater: $q_H = h_4 - h_3 = 632.4 - 304.3 = \mathbf{328.1\ kJ/kg}$

CV: entire unit, entropy equation per unit mass flow rate at state 1

$S_{C.V.,gen} = -\,q_H/T_H + \left(1 - (\dot{m}_7/\dot{m}_1)\right)s_5 + (\dot{m}_7/\dot{m}_1)s_7 - s_1$

$= (-328.1/473.15) + 0.9048 \times 1.3026 + 0.0952 \times 0.5053 - 0.2245$

$= 0.3088$ kJ/K-kg-m_1

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.171

A rigid 1.0 m^3 tank contains water initially at 120°C, with 50 % liquid and 50% vapor, by volume. A pressure-relief valve on the top of the tank is set to 1.0 MPa (the tank pressure cannot exceed 1.0 MPa - water will be discharged instead). Heat is now transferred to the tank from a 200°C heat source until the tank contains saturated vapor at 1.0 MPa. Calculate the heat transfer to the tank and show that this process does not violate the second law.

Solution:

C.V. Tank and walls out to the source. Neglect storage in walls. There is flow out and no boundary or shaft work.

Continuity Eq.4.15: $m_2 - m_1 = - m_e$

Energy Eq.4.16: $m_2 u_2 - m_1 u_1 = - m_e h_e + {}_1Q_2$

Entropy Eq.7.13: $m_2 s_2 - m_1 s_1 = - m_e s_e + \int dQ/T + {}_1S_{2\,gen}$

State 1: $T_1 = 120^oC$, Table B.1.1

$v_f = 0.00106\ m^3/kg$, $m_{liq} = 0.5V_1/v_f = 471.7$ kg

$v_g = 0.8919\ m^3/kg$, $m_g = 0.5V_1/v_g = 0.56$ kg,

$m_1 = 472.26$ kg, $x_1 = m_g/m_1 = 0.001186$

$u_1 = u_f + x_1 u_{fg} = 503.5 + 0.001186 \times 2025.8 = 505.88$ kJ/kg,

$s_1 = s_f + x_1 s_{fg} = 1.5275 + 0.001186 \times 5.602 = 1.5341$ kJ/kg-K

State 2: $P_2 = 1.0$ MPa, sat. vap. $x_2 = 1.0$, $V_2 = 1 m^3$

$v_2 = v_g = 0.19444\ m^3/kg$, $m_2 = V_2/v_2 = 5.14$ kg

$u_2 = u_g = 2583.6$ kJ/kg, $s_2 = s_g = 6.5864$ kJ/kg-K

Exit: $P_e = 1.0$ MPa, sat. vap. $x_e = 1.0$, $h_e = h_g = 2778.1$ kJ/kg,

$s_e = s_g = 6.5864$ kJ/kg, $m_e = m_1 - m_2 = 467.12$ kg

From the energy equation we get

$${}_1Q_2 = m_2 u_2 - m_1 u_1 + m_e h_e = \mathbf{1\ 072\ 080\ kJ}$$

From the entropy Eq.7.13 or Eq.7.24 (with 7.25 and 7.26) we get

$${}_1S_{2\,gen} = m_2 s_2 - m_1 s_1 + m_e s_e - \frac{{}_1Q_2}{T_H}; \qquad T_H = 200^oC = 473\ K$$

${}_1S_{2\,gen} = \Delta S_{net} = \mathbf{120.4\ kJ \geq 0}$ **Process Satisfies 2nd Law**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.172

A jet-ejector pump, shown schematically in Fig. P7.172, is a device in which a low-pressure (secondary) fluid is compressed by entrainment in a high-velocity (primary) fluid stream. The compression results from the deceleration in a diffuser. For purposes of analysis this can be considered as equivalent to the turbine-compressor unit shown in Fig. P7.165 with the states 1, 3, and 5 corresponding to those in Fig. P7.172. Consider a steam jet-pump with state 1 as saturated vapor at 35 kPa; state 3 is 300 kPa, 150°C; and the discharge pressure, P_5, is 100 kPa.

a. Calculate the ideal mass flow ratio, $\dot{m}_1/\dot{m}_3$.

b. The efficiency of a jet pump is defined as $\eta = (\dot{m}_1/\dot{m}_3)_{actual} / (\dot{m}_1/\dot{m}_3)_{ideal}$ for the same inlet conditions and discharge pressure. Determine the discharge temperature of the jet pump if its efficiency is 10%.

a) ideal processes (isen. comp. & exp.)

expands 3-4s
comp 1-2s } then mix at const. P

$s_{4s} = s_3 = 7.0778 = 1.3026 + x_{4s} \times 6.0568 \quad \Rightarrow \quad x_{4s} = 0.9535$

$h_{4s} = 417.46 + 0.9535 \times 2258.0 = 2570.5$ kJ/kg

$s_{2s} = s_1 = 7.7193 \rightarrow T_{2s} = 174°C \quad \& \quad h_{2s} = 2823.8$ kJ/kg

$\dot{m}_1(h_{2s} - h_1) = \dot{m}_3(h_3 - h_{4s})$

$$\Rightarrow (\dot{m}_1/\dot{m}_3)_{IDEAL} = \frac{2761.0 - 2570.5}{2823.8 - 2631.1} = \mathbf{0.9886}$$

b) real processes with jet pump eff. = 0.10

$\Rightarrow (\dot{m}_1/\dot{m}_3)_{ACTUAL} = 0.10 \times 0.9886 = 0.09886$

Energy Eq.: $\dot{m}_1 h_1 + \dot{m}_3 h_3 = (\dot{m}_1 + \dot{m}_3) h_5$

$0.09886 \times 2631.1 + 1 \times 2761.0 = 1.09896\, h_5$

State 5: $h_5 = 2749.3$ kJ/kg, $P_5 = 100$ kPa $\Rightarrow$ $T_5 = \mathbf{136.5\ ^oC}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.173

A horizontal, insulated cylinder has a frictionless piston held against stops by an external force of 500 kN. The piston cross-sectional area is 0.5 m^2, and the initial volume is 0.25 m^3. Argon gas in the cylinder is at 200 kPa, 100°C. A valve is now opened to a line flowing argon at 1.2 MPa, 200°C, and gas flows in until the cylinder pressure just balances the external force, at which point the valve is closed. Use constant heat capacity to verify that the final temperature is 645 K and find the total entropy generation.

Solution:

The process has inlet flow, no work (volume constant) and no heat transfer.

Continuity Eq.4.15: $m_2 - m_1 = m_i$

Energy Eq.4.16: $m_2 u_2 - m_1 u_1 = m_i h_i$

$m_1 = P_1V_1/RT_1 = 200 \times 0.25/(0.2081 \times 373.15) = 0.644$ kg

Force balance: $P_2A = F \quad \Rightarrow \quad P_2 = \dfrac{500}{0.5} = 1000$ kPa

For argon use constant heat capacities so the energy equation is:

$$m_2 \; C_{Vo} T_2 - m_1 \; C_{Vo} T_1 \; = (m_2 \; - m_1 \;) \; C_{Po} T_{in}$$

We know P_2 so only 1 unknown for state 2.

Use ideal gas law to write $m_2T_2 = P_2V_1/R$ and $m_1 T_1 = P_1V_1/R$

and divide the energy equation with C_{Vo} to solve for the change in mass

$$(P_2 V_1 \; - P_1V_1)/R \; = (m_2 \; - m_1 \;) \; (C_{Po}/C_{Vo} \;) \; T_{in}$$

$$(m_2 \; - m_1 \;) = (P_2 - P_1)V_1/(R \; k \; T_{in} \;)$$

$$= (1000 - 200) \times 0.25/(0.2081 \times 1.667 \times 473.15) = 1.219 \text{ kg}$$

$$m_2 = 1.219 + 0.644 = 1.863 \text{ kg.}$$

$T_2 = P_2V_1/(m_2R) = 1000 \times 0.25/(1.863 \times 0.2081) = 645$ K **OK**

Entropy Eq.7.12: $m_2s_2 - m_1s_1 = m_is_i + 0 + {}_1S_{2\,gen}$

$${}_1S_{2\,gen} = m_1(s_2 - s_1) + (m_2 - m_1)(s_2 - s_i)$$

$$= m_1\left[C_p \ln\frac{T_2}{T_1} - R \ln\frac{P_2}{P_1}\right] + (m_2 - m_1)\left[C_p \ln\frac{T_2}{T_i} - R \ln\frac{P_2}{P_i}\right]$$

$$= 0.644\left[0.52 \ln\frac{645}{373.15} - 0.2081 \ln\frac{1000}{200}\right]$$

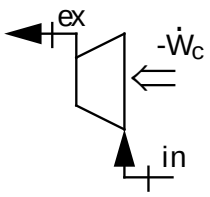
$$+ 1.219\left[0.52 \ln\frac{645}{473.15} - 0.2081 \ln\frac{1000}{1200}\right]$$

$$= -0.03242 + 0.24265 = \mathbf{0.21 \text{ kJ/K}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.174

Supercharging of an engine is used to increase the inlet air density so that more fuel can be added, the result of which is an increased power output. Assume that ambient air, 100 kPa and 27°C, enters the supercharger at a rate of 250 L/s. The supercharger (compressor) has an isentropic efficiency of 75%, and uses 20 kW of power input. Assume that the ideal and actual compressor have the same exit pressure. Find the ideal specific work and verify that the exit pressure is 175 kPa. Find the percent increase in air density entering the engine due to the supercharger and the entropy generation.



C.V.: Air in compressor (steady flow)

Cont: $\dot{m}_{in} = \dot{m}_{ex} = \dot{m} = \dot{V}/v_{in} = 0.29$ kg/s

Energy: $\dot{m}h_{in} - \dot{W} = \dot{m}h_{ex}$ Assume: $\dot{Q} = 0$

Entropy: $\dot{m}s_{in} + \dot{S}_{gen} = \dot{m}s_{ex}$

$$v_{in} = \frac{RT_{in}}{P_{in}} = 0.8614 \text{ m}^3/\text{kg}, \quad s^o_{Ti} = 6.86975 \text{ kJ/kg K}, \quad h_{in} = 300.62 \text{ kJ/kg}$$

$$\eta_c = w_{C\,s}/w_{C\,ac} \Rightarrow \quad -\dot{W}_S = -\dot{W}_{AC} \times \eta_c = 15 \text{ kW}$$

$$-w_{C\,s} = -\dot{W}_S/\dot{m} = 51.724 \text{ kJ/kg}, \quad -w_{C\,ac} = 68.966 \text{ kJ/kg}$$

Table A.7: $h_{ex\,s} = h_{in} - w_{C\,s} = 300.62 + 51.724 = 352.3$ kJ/kg

$$\Rightarrow T_{ex\,s} = 351.5 \text{ K}, \quad s^o_{Te} = 7.02830 \text{ kJ/kg K}$$

$$P_{ex} = P_{in} \times e^{(s^o_{T\,ex} - s^o_{T\,in})/R} = 100 \times \exp\left[\frac{7.0283 - 6.86975}{0.287}\right]$$

$$= \mathbf{173.75 \text{ kPa}}$$

The actual exit state is

$$h_{ex\,ac} = h_{in} - w_{C\,ac} = 369.6 \text{ kJ/kg} \Rightarrow T_{ex\,ac} = 368.6 \text{ K}$$

$$v_{ex} = RT_{ex}/P_{ex} = 0.6088 \text{ m}^3/\text{kg}, \quad s^o_{Tex\,ac} = 7.0764$$

$$\rho_{ex}/\rho_{in} = v_{in}/v_{ex} = 0.8614/0.6088 = \mathbf{1.415 \text{ or } 41.5\% \text{ increase}}$$

$$s_{gen} = s_{ex} - s_{in} = 7.0764 - 6.86975 - 0.287 \ln\left(\frac{173.75}{100}\right) = \mathbf{0.0481 \text{ kJ/kg K}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.175

A rigid steel bottle, V = 0.25 m^3, contains air at 100 kPa, 300 K. The bottle is now charged with air from a line at 260 K, 6 MPa to a bottle pressure of 5 MPa, state 2, and the valve is closed. Assume that the process is adiabatic, and the charge always is uniform. In storage, the bottle slowly returns to room temperature at 300 K, state 3. Find the final mass, the temperature T_2, the final pressure P_3, the heat transfer $_1Q_3$ and the total entropy generation.

C.V. Bottle. Flow in, no work, no heat transfer.

Continuity Eq.4.15: $m_2 - m_1 = m_{in}$;

Energy Eq.4.16: $m_2u_2 - m_1u_1 = m_{in}h_{in}$

State 1 and inlet: Table A.7, $u_1 = 214.36$ kJ/kg, $h_{in} = 260.32$ kJ/kg

$m_1 = P_1V/RT_1 = (100 \times 0.25)/(0.287 \times 300) = 0.290$ kg

$m_2 = P_2V/RT_2 = 5000 \times 0.25/(0.287 \times T_2) = 4355.4/T_2$

Substitute into energy equation : $u_2 + 0.00306\ T_2 = 260.32$ kJ/kg

Now trial and error on T_2

$T_2 = 360$ => LHS = 258.63 (low); $T_2 = 370$ => LHS = 265.88 (high)

Interpolation $T_2 = 362.3$ K (LHS = 260.3 OK)

$m_2 = 4355.4/362.3 = 12.022$ kg ; $P_3 = m_2RT_3/V =$ **4140 kPa**

Now use the energy equation from the beginning to the final state

$_1Q_3 = m_2u_3 - m_1u_1 - m_{in}h_{in} = (12.022 - 0.29)\ 214.36 - 11.732 \times 260.32$

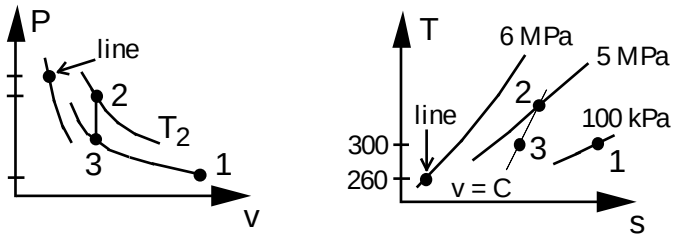
$=$ **-539.2 kJ**

Entropy equation from state 1 to state 3 with change in s from Eq.8.19

$S_{gen} = m_2s_3 - m_1s_1 - m_{in}s_{in} - {}_1Q_3/T = m_2(s_3 - s_{in}) - m_1(s_1 - s_{in}) - {}_1Q_3/T$

$= 12.022[6.8693 - 6.7256 - R \ln(4140/6000)]$

$- 0.29[6.8693 - 6.7256 - R \ln(100/6000)] + 539.2/300 =$ **4.423 kJ/K**



Problem could have been solved with constant specific heats from A.5 in which case we would get the energy explicit in T_2 (no iterations).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.176

A certain industrial process requires a steady 0.5 kg/s of air at 200 m/s, at the condition of 150 kPa, 300 K. This air is to be the exhaust from a specially designed turbine whose inlet pressure is 400 kPa. The turbine process may be assumed to be reversible and polytropic, with polytropic exponent n = 1.20.

a) What is the turbine inlet temperature?

b) What are the power output and heat transfer rate for the turbine?

c) Calculate the rate of net entropy increase, if the heat transfer comes from a source at a temperature 100°C higher than the turbine inlet temperature.

Solution:

C.V. Turbine, this has heat transfer, PV^n = Constant, n = 1.2

Process polytropic Eq.8.28: $T_e / T_i = (P_e/P_i)^{\frac{n-1}{n}}$ => $T_i = 353.3$ K

Energy Eq.4.12: $\dot{m}_i(h + \mathbf{V}^2/2)_{in} + \dot{Q} = \dot{m}_{ex}(h + \mathbf{V}^2/2)_{ex} + \dot{W}_T$

Reversible shaft work in a polytropic process, Eq.7.14 and Eq.7.18:

$$w_T = -\int v\, dP + (\mathbf{V}_i^2 - \mathbf{V}_e^2)/2 = -\frac{n}{n-1}(P_e v_e - P_i v_i) + (\mathbf{V}_i^2 - \mathbf{V}_e^2)/2$$

$$= -\frac{n}{n-1}R(T_e - T_i) - \mathbf{V}_e^2/2 = 71.8 \text{ kJ/kg}$$

$\dot{W}_T = \dot{m} w_T =$ **35.9 kW**

Assume constant specific heat in the energy equation

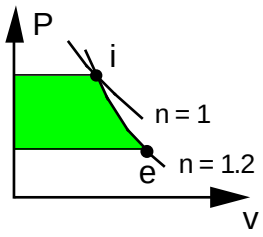
$\dot{Q} = \dot{m}[C_P (T_e - T_i) + \mathbf{V}_e^2/2] + \dot{W}_T =$ **19.2 kW**

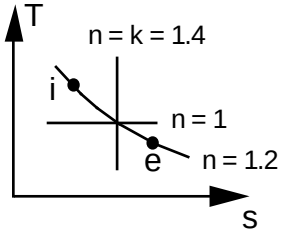
Entropy Eq.7.7 or 9.23 with change in entropy from Eq.8.16:

$dS_{net}/dt = \dot{S}_{gen} = \dot{m}(s_e - s_i) - \dot{Q}_H/T_H$, $T_H = T_i + 100 = 453.3$ K

$s_e - s_i = C_P \ln(T_e / T_i) - R \ln(P_e / P_i) = 0.1174$ kJ/kg K

$dS_{net}/dt = 0.5 \times 0.1174 - 19.2/453.3 = 0.0163$ kW/K





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Problems solved with P_r and v_r functions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.17 uses P_r function

Do the previous problem using the air tables in A.7
The exit nozzle in a jet engine receives air at 1200 K, 150 kPa with neglible kinetic energy. The exit pressure is 80 kPa and the process is reversible and adiabatic. Use constant heat capacity at 300 K to find the exit velocity.

Solution:
C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2 \quad (Z_i = Z_e)$

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

Process: $q = 0, \quad s_{gen} = 0$ as used above leads to $s_e = s_i$

Inlet state: $h_i = 1277.8$ kJ/kg, $\quad P_{r\,i} = 191.17$

The constant s is done using the P_r function from A.7.2

$$P_{r\,e} = P_{r\,i}\,(P_e / P_i) = 191.17\,(80/150) = 101.957$$

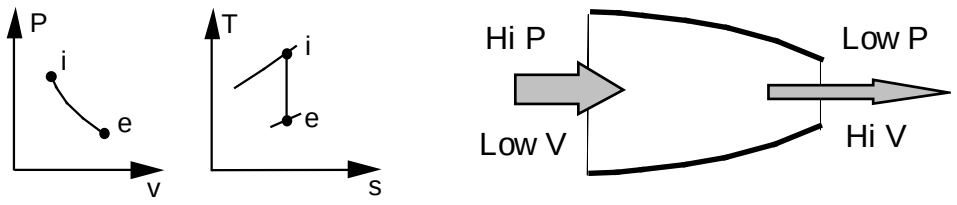
Interpolate in A.7 =>

$$T_e = 1000 + 50\,\frac{101.957 - 91.651}{111.35 - 91.651} = 1026.16 \text{ K}$$

$$h_e = 1046.2 + 0.5232 \times (1103.5 - 1046.2) = 1076.2 \text{ kJ/kg}$$

From the energy equation we have $\mathbf{V}_e^2/2 = h_i - h_e$, so then

$$\mathbf{V}_e = \sqrt{2\,(h_i - h_e)} = \sqrt{2(1277.8 - 1076.2)\text{ kJ/kg} \times 1000\text{ J/kJ}} = \mathbf{635\ m/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

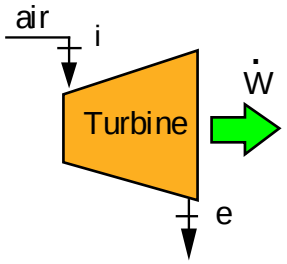
7.31 uses P_r function

Air enters a turbine at 800 kPa, 1200 K, and expands in a reversible adiabatic process to 100 kPa. Calculate the exit temperature and the work output per kilogram of air, using

a. The ideal gas tables, Table A.7

b. Constant specific heat, value at 300 K from table A.5

Solution:



C.V. Air turbine.

Adiabatic: $q = 0$, reversible: $s_{gen} = 0$

Energy Eq.4.13: $w_T = h_i - h_e$,

Entropy Eq.7.9: $s_e = s_i$

a) Table A.7: $h_i = 1277.8$ kJ/kg, $P_{r\,i} = 191.17$

The constant s process is done using the P_r function from A.7.2

$$\Rightarrow P_{r\,e} = P_{r\,i}\,(P_e / P_i) = 191.17 \left(\frac{100}{800}\right) = 23.896$$

Interpolate in A.7.1 $\Rightarrow$ T_e = **705.7 K**, $h_e = 719.7$ kJ/kg

$$w = h_i - h_e = 1277.8 - 719.7 = \mathbf{558.1\ kJ/kg}$$

b) Table A.5: $C_{Po} = 1.004$ kJ/kg K, $R = 0.287$ kJ/kg K, $k = 1.4$, then from Eq.8.23

$$T_e = T_i\,(P_e/P_i)^{\frac{k-1}{k}} = 1200 \left(\frac{100}{800}\right)^{0.286} = \mathbf{662.1\ K}$$

$$w = C_{Po}(T_i - T_e) = 1.004(1200 - 662.1) = \mathbf{539.8\ kJ/kg}$$

7.34 uses P_r function

A compressor receives air at 290 K, 95 kPa and a shaft work of 5.5 kW from a gasoline engine. It should deliver a mass flow rate of 0.01 kg/s air to a pipeline. Find the maximum possible exit pressure of the compressor.

Solution:

C.V. Compressor, Steady single inlet and exit flows. Adiabatic: $\dot{Q} = 0$.

Continuity Eq.4.11: $\dot{m}_i = \dot{m}_e = \dot{m}$,

Energy Eq.4.12: $\dot{m}h_i = \dot{m}h_e + \dot{W}_C$,

Entropy Eq.7.8: $\dot{m}s_i + \dot{S}_{gen} = \dot{m}s_e$ (Reversible $\dot{S}_{gen} = 0$)

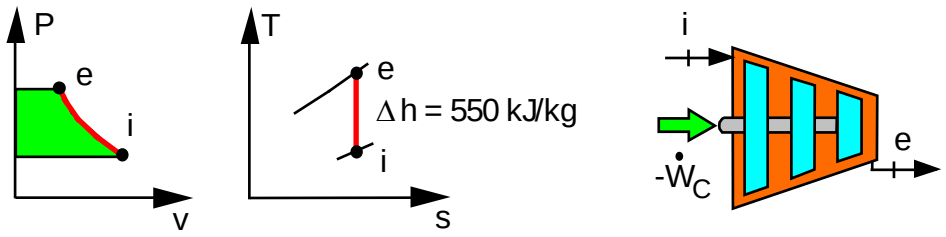
$$\dot{W}_c = \dot{m}w_c \quad => \quad -w_c = -\dot{W}/\dot{m} = 5.5/0.01 = 550 \text{ kJ/kg}$$

Use Table A.7, $h_i = 290.43$ kJ/kg, $P_{r\,i} = 0.9899$

$$h_e = h_i + (-w_c) = 290.43 + 550 = 840.43 \text{ kJ/kg}$$

A.7 => $T_e = 816.5$ K, $P_{r\,e} = 41.717$

$$P_e = P_i (P_{r\,e}/P_{r\,i}) = 95 \times (41.717/0.9899) = \mathbf{4003\ kPa}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.55 uses P_r function

An underground saltmine, 100 000 m^3 in volume, contains air at 290 K, 100 kPa. The mine is used for energy storage so the local power plant pumps it up to 2.1 MPa using outside air at 290 K, 100 kPa. Assume the pump is ideal and the process is adiabatic. Find the final mass and temperature of the air and the required pump work.

Solution:

C.V. The mine volume and the pump

Continuity Eq.4.15: $m_2 - m_1 = m_{in}$

Energy Eq.4.16: $m_2u_2 - m_1u_1 = {}_1Q_2 - {}_1W_2 + m_{in}h_{in}$

Entropy Eq.7.12: $m_2s_2 - m_1s_1 = \int dQ/T + {}_1S_{2\,gen} + m_{in}s_{in}$

Process: Adiabatic ${}_1Q_2 = 0$, Process ideal ${}_1S_{2\,gen} = 0$, $s_1 = s_{in}$

$\Rightarrow m_2s_2 = m_1s_1 + m_{in}s_{in} = (m_1 + m_{in})s_1 = m_2s_1 \Rightarrow s_2 = s_1$

Constant s $\Rightarrow$ $P_{r2} = P_{r\,i}\,(P_2 / P_i) = 0.9899 \left(\frac{2100}{100}\right) = 20.7879$

A.7.2 $\Rightarrow T_2 =$ **680 K** , $u_2 = 496.94$ kJ/kg

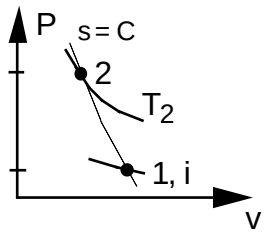
$m_1 = P_1V_1/RT_1 = 100{\times}10^5/(0.287 \times 290) = 1.20149 \times 10^5$ kg

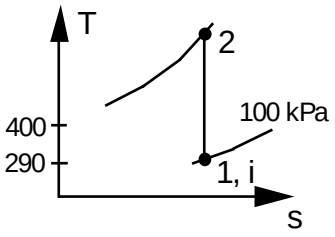
$m_2 = P_2V_2/RT_2 = 100 \times 21{\times}10^5/(0.287 \times 680) =$ **10.760×10^5 kg**

$\Rightarrow m_{in} = 9.5585{\times}10^5$ kg

${}_1W_2 = m_{in}h_{in} + m_1u_1 - m_2u_2$

$= m_{in}(290.43) + m_1(207.19) - m_2(496.94) =$ **-2.322×10^8 kJ**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.80 uses P_r function

Calculate the air temperature and pressure at the stagnation point right in front of a meteorite entering the atmosphere (-50 °C, 50 kPa) with a velocity of 2000 m/s. Do this assuming air is incompressible at the given state and repeat for air being a compressible substance going through an adiabatic compression.

Solution:

Kinetic energy: $\frac{1}{2}\mathbf{V}^2 = \frac{1}{2}(2000)^2/1000 = 2000$ kJ/kg

Ideal gas: $v_{atm} = RT/P = 0.287 \times 223/50 = 1.28$ m^3/kg

a) incompressible

Energy Eq.4.13: $\Delta h = \frac{1}{2}\mathbf{V}^2 = 2000$ kJ/kg

If A.5 $\Delta T = \Delta h/C_p = 1992$ K unreasonable, too high for that C_p

Use A.7: $h_{st} = h_o + \frac{1}{2}\mathbf{V}^2 = 223.22 + 2000 = 2223.3$ kJ/kg

$T_{st} = 1977$ K

Bernoulli (incompressible) Eq.7.17:

$$\Delta P = P_{st} - P_o = \frac{1}{2}\mathbf{V}^2/v = 2000/1.28 = 1562.5 \text{ kPa}$$

$P_{st} = 1562.5 + 50 = 1612.5$ kPa

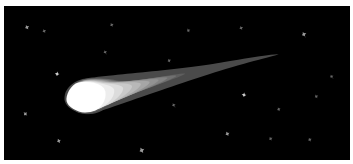
b) compressible

$T_{st} = 1977$ K the same energy equation.

From A.7.2: Stagnation point $P_{r\,st} = 1580.3$; Free $P_{r\,o} = 0.39809$

$$P_{st} = P_o \times \frac{P_{r\,st}}{P_{r\,o}} = 50 \times \frac{1580.3}{0.39809}$$

$$= \mathbf{198\ 485\ kPa}$$

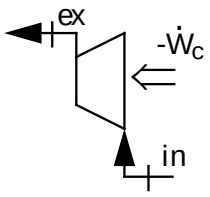


Notice that this is highly compressible, v is not constant.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.174 uses P_r function

Supercharging of an engine is used to increase the inlet air density so that more fuel can be added, the result of which is an increased power output. Assume that ambient air, 100 kPa and 27°C, enters the supercharger at a rate of 250 L/s. The supercharger (compressor) has an isentropic efficiency of 75%, and uses 20 kW of power input. Assume that the ideal and actual compressor have the same exit pressure. Find the ideal specific work and verify that the exit pressure is 175 kPa. Find the percent increase in air density entering the engine due to the supercharger and the entropy generation.



C.V.: Air in compressor (steady flow)

Cont: $\dot{m}_{in} = \dot{m}_{ex} = \dot{m} = \dot{V}/v_{in} = 0.29$ kg/s

Energy: $\dot{m}h_{in} - \dot{W} = \dot{m}h_{ex}$ Assume: $\dot{Q} = 0$

Entropy: $\dot{m}s_{in} + \dot{S}_{gen} = \dot{m}s_{ex}$

Inlet state: $v_{in} = RT_{in}/P_{in} = 0.8614$ m^3/kg, $P_{r\,in} = 1.1167$

$\eta_c = w_{C\,s}/w_{C\,ac}$ => $-\dot{W}_S = -\dot{W}_{AC} \times \eta_c = 15$ kW

$-w_{C\,s} = -\dot{W}_S/\dot{m} = 51.724$ kJ/kg, $-w_{C\,ac} = 68.966$ kJ/kg

Table A.7: $h_{ex\,s} = h_{in} - w_{C\,s} = 300.62 + 51.724 = 352.3$ kJ/kg

$\Rightarrow T_{ex\,s} = 351.5$ K, $P_{r\,ex} = 1.949$

$P_{ex} = P_{in} \times P_{r\,ex}/P_{r\,in} = 100 \times 1.949 / 1.1167 =$ **174.5 kPa**

The actual exit state is

$h_{ex\,ac} = h_{in} - w_{C\,ac} = 369.6$ kJ/kg $\Rightarrow T_{ex\,ac} = 368.6$ K

$v_{ex} = RT_{ex}/P_{ex} = 0.606$ m^3/kg

$\rho_{ex}/\rho_{in} = v_{in}/v_{ex} = 0.8614/0.606 =$ **1.42 or 42 % increase**

$s_{gen} = s_{ex} - s_{in} = 7.0767 - 6.8693 - 0.287 \ln(174/100)] =$ **0.0484 kJ/kg K**

Steady Single Flow Devices

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.177E

A compressor receives R-134a at 20 F, 30 psia with an exit of 200 psia, x = 1. What can you say about the process?

Solution:

Properties for R-134a are found in Table F.10

Inlet state: $s_i = 0.4157$ Btu/lbm R

Exit state: $s_e = 0.4080$ Btu/lbm R

Steady state single flow: $s_e = s_i + \int_i^e \frac{dq}{T} + s_{gen}$

Since s decreases slightly and the generation term can only be positive, it must be that the heat transfer is negative (out) so the integral gives a contribution that is smaller than $-s_{gen}$.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.178E

A condenser receives R-410A at 0 F and quality 80% with the exit flow being saturated liquid at 0 F. Consider the cooling to be a reversible process and find the specific heat transfer from the entropy equation.

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + q/T + 0$

$q = T\,(s_e - s_i) = T\,(s_f - s_i)$

Inlet: $s_i = 0.0306 + x_i\, 0.2257 = 0.21116$ Btu/lbm-R

Exit: $s_f = 0.0306$ Btu/lbm-R

$q = (459.67 + 0)\ \text{R} \times (0.0306 - 0.21116)$ Btu/lbm-R

$= -$ **83.0 Btu/lbm**

Remark: It fits with $h_e - h_i = -(1 - x_i)\, h_{fg} = -0.8 \times 103.76 = -83.0$ Btu/lbm

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.179E

Steam enters a turbine at 450 lbf/in.2, 900 F, expands in a reversible adiabatic process and exhausts at 130 F. Changes in kinetic and potential energies between the inlet and the exit of the turbine are small. The power output of the turbine is 800 Btu/s. What is the mass flow rate of steam through the turbine?

Solution:

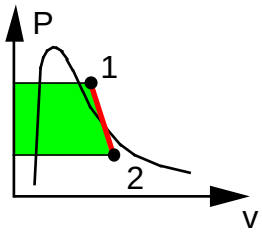
C.V. Turbine, Steady single inlet and exit flows. Adiabatic: $\dot{Q} = 0$.

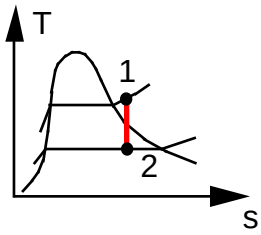
Continuity Eq.4.11: $\dot{m}_i = \dot{m}_e = \dot{m}$,

Energy Eq.4.12: $\dot{m}h_i = \dot{m}h_e + \dot{W}_T$,

Entropy Eq.7.8: $\dot{m}s_i + \emptyset = \dot{m}s_e$ (Reversible $\dot{S}_{gen} = 0$)

Explanation for the work term is in Sect. 7.3, Eq.7.14





Inlet state: Table F.7.2 $h_i = 1468.3$ btu/lbm, $s_i = 1.7113$ btu/lbm R

Exit state: $s_e = 1.7113$ Btu/lbm R, $T_e = 130$ F $\Rightarrow$ saturated

$x_e = (1.7113 - 0.1817)/1.7292 = 0.8846$,

$h_e = 97.97 + x_e\ 1019.78 = 1000$ Btu/lbm

$w = h_i - h_e = 1468.3 - 1000 = 468.3$ Btu/lbm

$\dot{m} = \dot{W} / w = (800 \text{ Btu/s}) / (468.3 \text{ Btu/lbm}) =$ **1.708 lbm/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.180E

The exit nozzle in a jet engine receives air at 2100 R, 20 psia with neglible kinetic energy. The exit pressure is 10 psia and the process is reversible and adiabatic. Use constant heat capacity at 77 F to find the exit velocity.

Solution:
C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2 \quad (Z_i = Z_e)$

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

Use constant specific heat from Table F.4, $C_{Po} = 0.24 \frac{\text{Btu}}{\text{lbm R}}$, $k = 1.4$

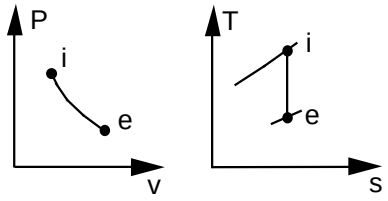
The isentropic process ($s_e = s_i$) gives Eq.6.23

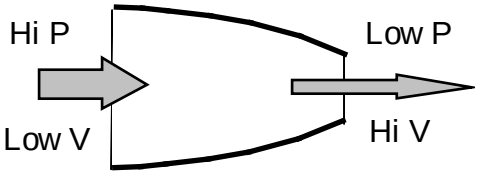
$$\Rightarrow \quad T_e = T_i (P_e/P_i)^{\frac{k-1}{k}} = 2100\ (10/20)^{0.2857} = 1722.7 \text{ R}$$

The energy equation becomes (conversion 1 Btu/lbm = 25 037 ft^2/s^2 in A.1)

$$\mathbf{V}_e^2/2 = h_i - h_e \cong C_P (T_i - T_e)$$

$$\mathbf{V}_e = \sqrt{2\, C_P (T_i - T_e)} = \sqrt{2 \times 0.24 (2100 - 1722.7) \times 25\,037} = \mathbf{2129\ ft/s}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.181E

Do the previous problem using Table F.5.
The exit nozzle in a jet engine receives air at 2100 R, 20 psia with neglible kinetic energy. The exit pressure is 10 psia and the process is reversible and adiabatic. Use constant heat capacity at 77 F to find the exit velocity.

Solution:
C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2 \quad (Z_i = Z_e)$

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

The constant s is rewritten from Eq.6.19 as

$$s^o_{Te} = s^o_{Ti} + R \ln(P_e / P_i) = 1.98461 + \frac{53.34}{778} \ln (10/20) = 1.937088 \text{ Btu/lbmR}$$

Interpolate in F.5 =>

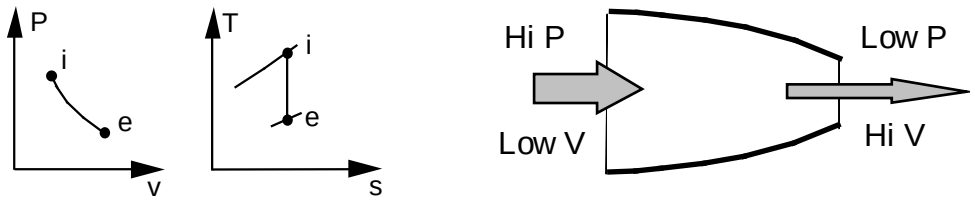
$$T_e = 1750 + 50 \frac{1.937088 - 1.93444}{1.94209 - 1.93444} = 1750 + 50 \times 0.34608 = 1767.3 \text{ R}$$

$$h_e = 436.205 + (449.794 - 436.205) \times 0.34608 = 440.908 \text{ Btu/lbm}$$

The energy equation becomes (conversion 1 Btu/lbm = 25 037 ft^2/s^2 in A.1)

$$\mathbf{V}_e^2/2 = h_i - h_e = 532.57 - 440.908 = 91.662 \text{ Btu/lbm}$$

$$\mathbf{V}_e = \sqrt{2 (h_i - h_e)} = \sqrt{2 \times 91.662 \times 25\,037} = \mathbf{2142 \text{ ft/s}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.182E

In a heat pump that uses R-134a as the working fluid, the R-134a enters the compressor at 30 lbf/in.^{2}, 20 F. In the compressor the R-134a is compressed in an adiabatic process to 150 lbf/in.^{2} using 1.5 Btu/s of power. Find the mass flow rate it can provide assuming the process is reversible.

Solution:

C.V. Compressor, Steady single inlet and exit flows. Adiabatic: $\dot{Q} = 0$.

Continuity Eq.4.11: $\dot{m}_1 = \dot{m}_2 = \dot{m}$,

Energy Eq.4.12: $\dot{m}h_1 = \dot{m}h_2 + \dot{W}_C$,

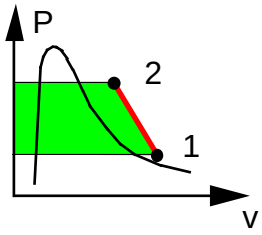
Entropy Eq.7.8: $\dot{m}s_1 + \emptyset = \dot{m}s_2$ (Reversible $\dot{S}_{gen} = 0$)

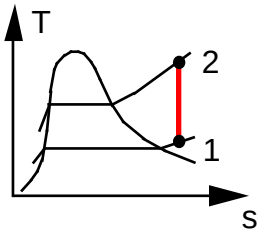
Inlet state: Table F.10.2 $h_1 = 169.82$ Btu/lbm, $s_1 = 0.4157$ Btu/lbm R

Exit state: $P_2 = 150$ psia & $s_2 \Rightarrow h_2 = 184.46$ Btu/lbm

$\dot{m} = \dot{W}_c/w_c = \dot{W}_c/(h_1 - h_2) = -1.5/(169.82 - 184.46) =$ **0.102 lbm/s**

Explanation for the work term is in Sect. 7.3 Eq.7.14





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.183E

A compressor in a commercial refrigerator receives R-410A at -10 F and unknown quality. The exit is at 300 psia, 140 F and the process assumed reversible and adiabatic. Neglect kinetic energies and find the inlet quality and the specific work.

CV Compressor. q = 0.

Energy Eq.4.13: $w_C = h_i - h_e$

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

Exit state: 300 psia, 140 F $s = s_i$

Table F.9.2 $\Rightarrow$ $h_e = 137.34$ Btu/lbm, $s_e = s_i = 0.2582$ Btu/lbm-R

Inlet state: F.9.1: T, $s_i = s_e$

$x_i = (0.2582 - 0.0231)/0.2362 = 0.99534$

$h_i = 10.08 + x_i\ 106.2 = 115.78$ Btu/lbm

$w_C = 115.78 - 137.34 = -$**21.56 Btu/lbm**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.184E

A compressor brings a hydrogen gas flow at 500 R, 1 atm up to a pressure of 10 atm in a reversible process. How hot is the exit flow and what is the specific work input?

CV Compressor. Assume q = 0.

Energy Eq.4.13: $w_C = h_i - h_e \approx C_p (T_i - T_e)$

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

Properties from Table F.4 and constant s from Eq.6.23

$T_e = T_i (P_e/P_i)^{(k-1)/k} = 500\ R\ (10/1)^{(1.409-1)/1.409} =$ **975.5 R**

Now the work from the energy equation, C_p from F.4

$w_C = 3.394$ Btu/lbm-R × (500 – 975.5) R = **-1613.8 Btu/lbm**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.185E

A flow of 4 lbm/s saturated vapor R-410A at 100 psia is heated at constant pressure to 140 F. The heat is supplied by a heat pump that receives heat from the ambient at 540 R and work input, shown in Fig. P7.28. Assume everything is reversible and find the rate of work input.

Solution:

C.V. Heat exchanger

Continuity Eq.: $\dot{m}_1 = \dot{m}_2$;

Energy Eq.: $\dot{m}_1 h_1 + \dot{Q}_H = \dot{m}_1 h_2$

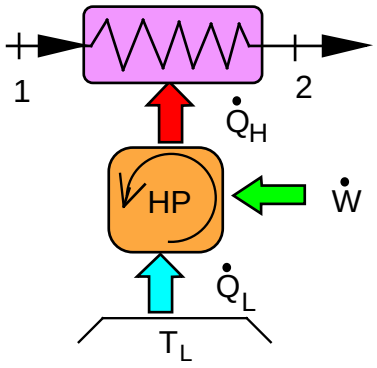
Table F.9.2:

h_1 = 119.38 Btu/lbm,

s_1 = 0.2498 Btu/lbm R

h_2 = 146.13 Btu/lbm,

s_2 = 0.2994 Btu/lbm R



Notice we can find $\dot{Q}_H$ but the temperature T_H is not constant making it difficult to evaluate the COP of the heat pump.

C.V. Total setup and assume everything is reversible and steady state.

Energy Eq.: $\dot{m}_1 h_1 + \dot{Q}_L + \dot{W} = \dot{m}_1 h_2$

Entropy Eq.: $\dot{m}_1 s_1 + \dot{Q}_L / T_L + 0 = \dot{m}_1 s_2$ (T_L is constant, $s_{gen} = 0$)

$\dot{Q}_L = \dot{m}_1 T_L [s_2 - s_1] = 4 \times 540 [0.2994 - 0.2498] = 107.14$ Btu/s

$\dot{W} = \dot{m}_1 [h_2 - h_1] - \dot{Q}_L = 4 (146.13 - 119.38) - 107.14 =$ **-0.14 Btu/s**

Comment: Net work is nearly zero, due to the very low inlet T so the first heating of the flow actually generates work out and only the heating to above ambient T requires work input.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.186E

A diffuser is a steady-state, steady-flow device in which a fluid flowing at high velocity is decelerated such that the pressure increases in the process. Air at 18 lbf/in.^{2}, 90 F enters a diffuser with velocity 600 ft/s and exits with a velocity of 60 ft/s. Assuming the process is reversible and adiabatic what are the exit pressure and temperature of the air?

C.V. Diffuser, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i + \mathbf{V}_i^2/2g_c = h_e + \mathbf{V}_e^2/2g_c$, => $h_e - h_i = C_{Po}(T_e - T_i)$

Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_i + 0 + 0 = s_e$ (Reversible, adiabatic)

Energy equation then gives (conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1):

$$C_{Po}(T_e - T_i) = 0.24(T_e - 549.7) = \frac{600^2 - 60^2}{2 \times 25\,037}$$

$$T_e = \mathbf{579.3\ R}$$

The isentropic process ($s_e = s_i$) gives Eq.6.23

$$P_e = P_i(T_e/T_i)^{\frac{k}{k-1}} = 18\left(\frac{579.3}{549.7}\right)^{3.5} = \mathbf{21.6\ lbf/in^2}$$

7.187E

An expander receives 1 lbm/s air at 300 psia, 540 R with an exit state of 60 psia, 540 R. Assume the process is reversible and isothermal. Find the rates of heat transfer and work neglecting kinetic and potential energy changes.

Solution:

C.V. Expander, single steady flow.

Energy Eq.: $\dot{m}h_i + \dot{Q} = \dot{m}h_e + \dot{W}$

Entropy Eq.: $\dot{m}s_i + \dot{Q}/T + \dot{m}s_{gen} = \dot{m}s_e$

Process: T is constant and $s_{gen} = 0$

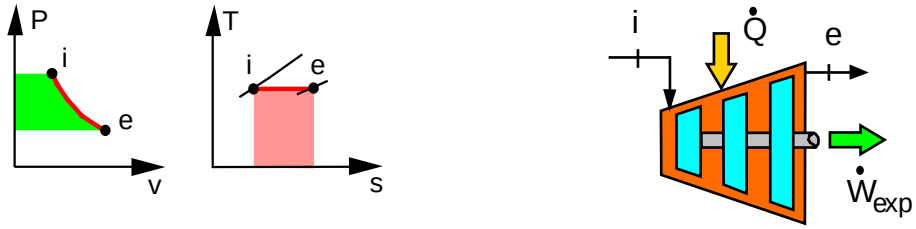
Ideal gas and isothermal gives a change in entropy by Eq. 6.15, so we can solve for the heat transfer

$$\dot{Q} = T\dot{m}(s_e - s_i) = -\dot{m}RT \ln \frac{P_e}{P_i}$$

$$= -\ 1\ \text{lbm/s} \times 540\ \text{R} \times \frac{53.34}{778}\ \text{Btu/lbm-R} \times \ln \frac{60}{300} = \mathbf{59.6\ Btu/s}$$

From the energy equation we get

$$\dot{W} = \dot{m}(h_i - h_e) + \dot{Q} = \dot{Q} = \mathbf{59.6\ Btu/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.188E

One technique for operating a steam turbine in part-load power output is to throttle the steam to a lower pressure before it enters the turbine, as shown in Fig. P7.39. The steamline conditions are 200 lbf/in.^{2}, 600 F, and the turbine exhaust pressure is fixed at 1 lbf/in.^{2}. Assuming the expansion inside the turbine to be reversible and adiabatic, determine the specific turbine work for no throttling and the specific turbine work (part-load) if it is throttled to 60 psia. Show both processes in a *T*–*s* diagram.

C.V. Turbine full-load, reversible.

Entropy Eq.7.9 reduces to constant s so from Table F.7.2 and F.7.1

$$s_{3a} = s_1 = 1.6767 \text{ Btu/lbm R} = 0.132\ 66 + x_{3a} \times 1.8453$$

$$x_{3a} = 0.8367$$

$$h_{3a} = 69.74 + 0.8367 \times 1036.0 = 936.6 \text{ Btu/lbm}$$

$$_1w_{3a} = h_1 - h_{3a} = 1322.05 - 936.6 = \mathbf{385.45\ Btu/lbm}$$

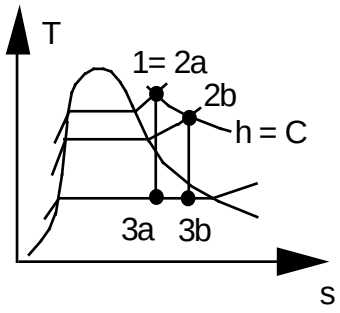
The energy equation for the part load operation gives the exit h. Notice that we have constant h in the throttle process, $h_2 = h_1$:

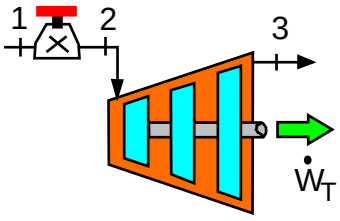
2b: P, $h_{2b} = h_1 = 1322.05$ btu/lbm => $s_{2b} = 1.80656$ Btu/lbmR

3b: P, $s = s_{2b} = 1.80656$ => $x_{3b} = (1.80656 - 0.132\ 66)/1.8453 = 0.90711$

$$h_{3b} = 69.74 + x_{3b} \times 1036.0 = 1009.5 \text{ Btu/lbm}$$

$$w_T = 1322.05 - 1009.5 = \mathbf{312.54\ Btu/lbm}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.189E

An adiabatic air turbine receives 2 lbm/s air at 2700 R, 240 psia and 4 lbm/s air at 60 psia, T_2 in a setup similar to Fig. P4.87 with an exit flow at 15 psia. What should the temperature T_2 be so the whole process can be reversible?

The process is reversible if we do not generate any entropy. Physically in this problem it means that state 2 must match the state inside the turbine so we do not mix fluid at two different temperatures (we assume the pressure inside is exactly 60 psia).

For this reason let us select the front end as C.V. and consider the flow from state 1 to the 60 psia. This is a single flow

Entropy Eq.7.9: $s_1 + 0/T + 0 = s_2$;

Property Eq.6.19 $s_2 - s_1 = 0 = s^o_{T2} - s^o_{T1} - R \ln(P_2 / P_1)$

$$s^o_{T2} = s^o_{T1} + R \ln(P_2 / P_1) = 2.05606 + \frac{53.34}{778} \ln \frac{60}{240} = 1.9610 \text{ Btu/lbm-R}$$

From F.5: $T_2 =$ **1928.8 R**

If we solve with constant specific heats we get from Eq.6.23 and k = 1.4

$$T_2 = T_1 (P_2 / P_1)^{(k-1)/k} = 2700 \text{ R } (60/240)^{0.2857} = 1817 \text{ R}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.190E

A 20 ft^3 tank contains carbon dioxide at 540 R, 20 psia is now filled from a supply of carbon dioxide at 540 R, 20 psia by a compressor to a final tank pressure of 60 psia. Assume the whole process is adiabatic and reversible. Find the final mass and temperature in the tank and the required work to the compressor.

C.V. The tank and the compressor.

Continuity Eq.4.15: $m_2 - m_1 = m_{in}$

Energy Eq.4.16: $m_2u_2 - m_1u_1 = {}_1Q_2 - {}_1W_2 + m_{in}h_{in}$

Entropy Eq.7.13: $m_2s_2 - m_1s_1 = \int dQ/T + {}_1S_{2\,gen} + m_{in}s_{in}$

Process: Adiabatic ${}_1Q_2 = 0$, Process ideal ${}_1S_{2\,gen} = 0$, $s_1 = s_{in}$

$\Rightarrow m_2s_2 = m_1s_1 + m_{in}s_{in} = (m_1 + m_{in})s_1 = m_2s_1 \Rightarrow s_2 = s_1$

Constant s so since the temperatures are modest use Eq.6.23

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 540\ \text{R}\ (60/20)^{0.2242} = \mathbf{690.8\ R}$$

$$m_1 = P_1V_1/RT_1 = \frac{20 \times 20 \times 144}{35.1 \times 540} = 3.039\ \text{lbm}$$

$m_2 = P_2V_2/RT_2 = 60 \times 20 \times 144/(35.1 \times 690.8) =$ **7.127 lbm**

$\Rightarrow m_{in} = 4.088$ lbm

${}_1W_2 = m_{in}h_{in} + m_1u_1 - m_2u_2 = m_{in}RT_{in} + m_1(u_1 - u_{in}) - m_2(u_2 - u_{in})$

$= 4.088\ (35.1 \times 540/778) + m_1\ (0) - 7.127 \times 0.156\ (690.8 - 540)$

$=$ **-68.07 Btu** (work must come in)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.191E

An underground saltmine, 3.5 × 106 ft^3 in volume, contains air at 520 R, 14.7 lbf/in.^{2}. The mine is used for energy storage so the local power plant pumps it up to 310 lbf/in.^{2} using outside air at 520 R, 14.7 lbf/in.^{2}. Assume the pump is ideal and the process is adiabatic. Find the final mass and temperature of the air and the required pump work. Overnight, the air in the mine cools down to 720 R. Find the final pressure and heat transfer.

C.V. The mine volume and the pump

Continuity Eq.4.15: $m_2 - m_1 = m_{in}$

Energy Eq.4.16: $m_2u_2 - m_1u_1 = {}_1Q_2 - {}_1W_2 + m_{in}h_{in}$

Entropy Eq.7.13: $m_2s_2 - m_1s_1 = \int dQ/T + {}_1S_{2\,gen} + m_{in}s_{in}$

Process: Adiabatic ${}_1Q_2 = 0$, Process ideal ${}_1S_{2\,gen} = 0$, $s_1 = s_{in}$

$\Rightarrow m_2s_2 = m_1s_1 + m_{in}s_{in} = (m_1 + m_{in})s_1 = m_2s_1 \Rightarrow s_2 = s_1$

Constant s $\Rightarrow$ Eq.6.19 $s^o_{T2} = s^o_{Ti} + R \ln(P_e / P_i)$

Table F.4 $\Rightarrow s^o_{T2} = 1.63074 + \frac{53.34}{778} \ln(\frac{310}{14.7}) = 1.83976$ Btu/lbm R

$\Rightarrow T_2 =$ **1221 R** , $u_2 = 213.13$ Btu/lbm

Now we have the states and can get the masses

$$m_1 = P_1V_1/RT_1 = \frac{14.7 \times 3.5\times10^6 \times 144}{53.34 \times 520} = 2.671\times10^5 \text{ lbm}$$

$$m_2 = P_2V_2/RT_2 = \frac{310 \times 3.5\times10^6 \times 144}{53.34 \times 1221} = \mathbf{2.4 \times 10^6 \text{ lbm}}$$

$\Rightarrow m_{in} = m_2 - m_1 = 2.1319\times10^6$ lbm

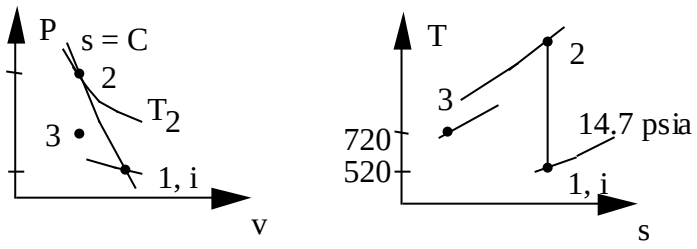
${}_1W_2 = m_{in}h_{in} + m_1u_1 - m_2u_2 = 2.1319\times10^6 \times 124.38 + 2.671\times10^5$

$\times 88.73 - 2.4\times10^6 \times 213.13 = -2.226 \times 10^8$ Btu = -pump work in

$W_{pump} =$ **2.23×10^8 Btu**

${}_2W_3 = \emptyset$, $P_3 = P_2T_3/T_2 = 310\times720/1221 =$ **182.8 lbf/in^2**

${}_2Q_3 = m_2(u_3 - u_2) = 2.4\times10^6(123.17 - 213.13) =$ **-2.16×10^8 Btu**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.192E

R-410A at 240 F, 600 psia is in an insulated tank and flow is now allowed out to a turbine with a backup pressure of 125 psia. The flow continues to a final tank pressure of 125 psia and the process stops. If the initial mass was 1 lbm how much mass is left in the tank and what is the turbine work assuming a reversible process?

Solution:

C.V. Total tank and turbine.

Continuity Eq.4.15: $m_2 - m_1 = -m_{ex}$

Energy Eq.4.16: $m_2u_2 - m_1u_1 = -m_{ex}h_{ex} + {}_1Q_2 - {}_1W_2$

Entropy Eq.7.12: $m_2s_2 - m_1s_1 = -m_{ex}s_{ex} + \int dQ/T + {}_1S_{2\,gen}$

Process: Adiabatic ${}_1Q_2 = 0$; Reversible ${}_1S_{2\,gen} = 0$

This has too many unknowns (we do not know state 2 only P_2).

C.V. m_2 the mass that remains in the tank. This is a control mass.

Entropy Eq.6.3 (6.37): $m_2(s_2 - s_1) = \int dQ/T + {}_1S_{2\,gen}$

Process: Adiabatic ${}_1Q_2 = 0$; Reversible ${}_1S_{2\,gen} = 0$

$\Rightarrow \quad s_2 = s_1$

State 1: $v_1 = 0.1342$ ft^3/lbm, $u_1 = 139.96$ Btu/lbm, $s_1 = 0.2703$ Btu/lbm-R

State 2 (P,s): $T_2 = 86.05$ F, $v_2 = 0.5722$ ft^3/lbm, $u_2 = 119.45$ Btu/lbm

State exit: $s_{ex} = s_2 = s_1$ follows from entropy Eq. for first C.V. using the continuity eq., this is identical to state 2, $h_{ex} = 132.695$ Btu/lbm

Tank volume constant so $V = m_1v_1 = m_2v_2$

$m_2 = m_1\, v_1 / v_2 = 1 \times 0.1342 / 0.5722 =$ **0.2345 lbm**

From energy eq.

${}_1W_2 = m_1u_1 - m_2u_2 - m_{ex}h_{ex}$

$= 1 \times 139.96 - 0.2345 \times 119.45 - 0.7655 \times 132.695$ [Btu]

= **10.37 Btu**

Reversible Shaft Work, Bernoulli

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.193E

A river flowing at 2 ft/s across 3 ft high and 30 ft wide area has a dam that creates an elevation difference of 7 ft. How much energy can a turbine deliver per day if 80% of the potential energy can be extracted as work?

CV Dam from upstream to downstream 2 m lower elevation

Continuity Eq.: $\dot{m} = \text{constant} = \dot{m}_e = \dot{m}_i = A_e \mathbf{V}_e / v_e = A_i \mathbf{V}_i / v_i$

Find the mass flow rate

$$\dot{m} = A\mathbf{V}_i / v = \rho A \mathbf{V}_i = 62.2 \text{ lbm/ft}^3 \times (3 \times 30) \text{ ft}^2 \times 2 \text{ ft/s} = 11\,196 \text{ lbm/s}$$

Energy Eq.: $0 = \dot{m} (h_i + 0.5\mathbf{V}_i^2 + gZ_i) - \dot{m} (h_e + 0.5\mathbf{V}_e^2 + gZ_e) - \dot{W}$

The velocity in and out is the same assuming same flow area and the two enthalpies are also the same since same T and $P = P_0$.

This is consistent with Eq.7.14 [$w = g(Z_i - Z_e)$ - loss]

$$\dot{W} = 0.8\, \dot{m}\, g(Z_i - Z_e) = 0.8 \times 11\,196 \text{ lbm/s} \times 32.174 \text{ ft/s}^2 \times 7 \text{ ft}$$
$$= (2\,017\,232 / 25\,037) \text{ Btu/s} = 80.57 \text{ Btu/s}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1

$$W = \dot{W}\, \Delta t = 80.57 \text{ (Btu/s)} \times 24 \times 60 \times 60 \text{ s} = \mathbf{6.96 \text{ MBtu}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.194E

How much liquid water at 60 F can be pumped from 14.7 psia to 35 psia with a 3 kW motor?

Incompressible flow (liquid water) and we assume reversible. Then the shaftwork is from Eq.7.15 (7.16)

$$w = -\int v\, dP = -v\, \Delta P = -0.016 \text{ ft}^3/\text{lbm } (35 - 14.7) \text{ psia}$$

$$= -46.77 \text{ lbf-ft/lbm} = -0.06 \text{ Btu/lbm}$$

$$\dot{W} = 3 \text{ kW} = 2.844 \text{ Btu/s}$$

$$\dot{m} = \frac{\dot{W}}{-w} = \frac{2.844}{0.06} = \mathbf{47.4 \text{ lbm/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

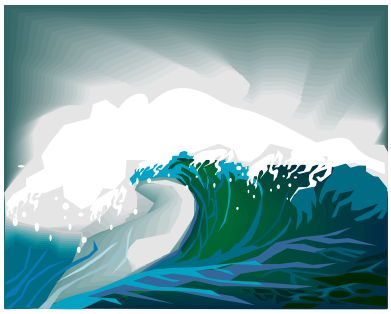
7.195E

A wave comes rolling in to the beach at 6 ft/s horizontal velocity. Neglect friction and find how high up (elevation) on the beach the wave will reach.

We will assume a steady reversible single flow at constant pressure and temperature for the incompressible liquid water. The water will flow in and up the sloped beach until it stops ($\mathbf{V}$ = 0) so Bernoulli Eq.7.17 leads to

$$gz_{in} + \frac{1}{2}\mathbf{V}^2_{in} = gz_{ex} + 0$$

$$(z_{ex} - z_{in}) = \frac{1}{2g}\mathbf{V}^2_{in} = \frac{1}{2 \times 32.174 \text{ ft/s}^2}\, 6^2 \text{ (ft/s)}^2 = \mathbf{0.56 \text{ ft}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.196E

A small pump takes in water at 70 F, 14.7 lbf/in.^{2} and pumps it to 250 lbf/in.^{2} at a flow rate of 200 lbm/min. Find the required pump power input.

Solution:

C.V. Pump. Assume reversible pump and incompressible flow.

This leads to the work in Eq.7.15

$$w_p = -\int v dP = -v_i(P_e - P_i)$$

$$= -0.01605 \text{ ft}^3/\text{lbm } (250 - 14.7) \text{ psi} \times \frac{144 \text{ in}^2/\text{ft}^2}{778 \text{ lbf-ft/(Btu/lbm)}}$$

$$= -0.7 \text{ Btu/lbm}$$

$$\dot{W}_{p \text{ in}} = \dot{m}(-w_p) = \frac{200}{60} \text{ lbm/s } (0.7 \text{ Btu/lbm}) = \mathbf{2.33 \text{ Btu/s} = 3.3 \text{ hp}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.197E

An irrigation pump takes water from a river at 50 F, 1 atm and pumps it up to an open canal at a 150 ft higher elevation. The pipe diameter in and out of the pump is 0.3 ft and the motor driving the pump is 5 hp. Neglect kinetic energies and friction, find the maximum possible mass flow rate.

CV the pump. The flow is incompressible and steady flow. The pump work is the difference between the flow work in and out and from Bernoulli's eq. for the pipe that is equal to the potential energy increase sincle pump inlet pressure and pipe outlet pressure are the same.

$$w_p = v\,\Delta P = g\,\Delta Z = 32.174 \text{ ft/s}^2 \times 150 \text{ ft}$$

$$= 4826.1 \text{ (ft/s)}^2 = (4826.1 / 25037) \text{ Btu/lbm} = 0.19276 \text{ Btu/lbm}$$

The horsepower is converted from Table A.1

$$\dot{W}_{motor} = 5 \text{ hp} = 5 \times 2544 \text{ Btu/h} = 12\,720 \text{ btu/h} = 3.533 \text{ Btu/s}$$

$$\dot{m} = \dot{W}_{motor} / w_p = 3.533 / 0.19276 = \mathbf{18.33 \text{ lbm/s}}$$

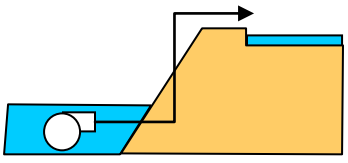
Comment:

$$\dot{m} = AV/v \quad \Rightarrow \quad V = \frac{\dot{m}v}{A} = \frac{4\dot{m}}{\rho\,\pi\,D^2} = \frac{4 \times 18.33}{62.2 \times \pi \times 0.3^2} = 4.17 \text{ ft/s}$$

The power to generated the kinetic energy is

$$\text{Power} = \dot{m}\, 0.5\, V^2 = 18.33 \times 0.5 \times 4.17^2 / 25037 = 0.0064 \text{ Btu/s}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1
This is insignificant relative to the power needed for the potential energy increase.



Pump inlet and the pipe exit both have close to atmospheric pressure.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.198E

A fireman on a ladder 80 ft above ground should be able to spray water an additional 30 ft up with the hose nozzle of exit diameter 1 in. Assume a water pump on the ground and a reversible flow (hose, nozzle included) and find the minimum required power.

Solution:

C.V.: pump + hose + water column, total height difference 35 m.

Continuity Eq.4.3, 4.11: $\dot{m}_{in} = \dot{m}_{ex} = (\rho A \mathbf{V})_{nozzle}$

Energy Eq.4.12: $\dot{m}(-w_p) + \dot{m}(h + \mathbf{V}^2/2 + gz)_{in} = \dot{m}(h + \mathbf{V}^2/2 + gz)_{ex}$

Process: $h_{in} \cong h_{ex}$, $\mathbf{V}_{in} \cong \mathbf{V}_{ex} = 0$, $z_{ex} - z_{in} = 110$ ft, $\rho = 1/v \cong 1/v_f$

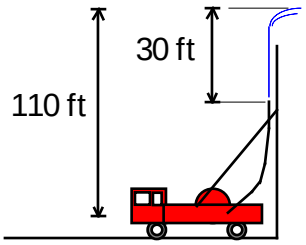
$$-w_p = g(z_{ex} - z_{in}) = 32.174 \times (110 - 0)/25\,037 = 0.141 \text{ Btu/lbm}$$

Recall the conversion 1 Btu/lbm = 25 037 ft^2/s^2 from Table A.1. The velocity in the exit nozzle is such that it can rise 30 ft. Make that column a C.V. for which Bernoulli Eq.7.17 is:

$$gz_{noz} + \frac{1}{2}\mathbf{V}^2_{noz} = gz_{ex} + 0$$

$$\mathbf{V}_{noz} = \sqrt{2g(z_{ex} - z_{noz})}$$

$$= \sqrt{2 \times 32.174 \times 30} = 43.94 \text{ ft/s}$$



Assume: $v = v_{F,70F} = 0.01605$ ft^3/lbm

$$\dot{m} = \frac{\pi}{v_f}\left(\frac{D}{2}\right)^2 \mathbf{V}_{noz} = (\pi/4)\,(1^2/144) \times 43.94 / 0.01605 = 14.92 \text{ lbm/s}$$

$$\dot{W}_{pump} = \dot{m} w_p = 14.92 \times 0.141 \times (3600/2544) = \mathbf{3\ hp}$$

7.199E

Saturated R-410A at 10 F is pumped/compressed to a pressure of 300 lbf/in.^{2} at the rate of 1.0 lbm/s in a reversible adiabatic steady flow process. Calculate the power required and the exit temperature for the two cases of inlet state of the R-410A:

a) quality of 100 %.
b) quality of 0 %.

Solution:

C.V.: Pump/Compressor, $\dot{m}$ = 1 lbm/s, R-410A

a) State 1: Table F.10.1, $x_1 = 1.0$ Saturated vapor, $P_1 = P_g = 76.926$ psia,

$h_1 = h_g = 118.21$ Btu/lbm, $s_1 = s_g = 0.2535$ Btu/lbm R

Assume Compressor is isentropic, $s_2 = s_1 = 0.2535$ Btu/lbm R

$h_2 = 134.54$ Btu/lbm, **T_2 = 130.5 F**

Energy Eq.4.13: $q_C + h_1 = h_2 + w_C$; $q_C = 0$

$w_{CS} = h_1 - h_2 = 118.21 - 134.54 = -16.33$ Btu/lbm;

=> $\dot{W}_C = \dot{m} w_C$ = **-16.3 Btu/s = -23.1 hp**

b) State 1: $T_1 = 10$ F, $x_1 = 0$ Saturated liquid. This is a pump.

$P_1 = 76.926$ psia, $h_1 = h_f = 17.0$ Btu/lbm, $v_1 = v_f = 0.01316$ ft^3/lbm

Energy Eq.4.13: $q_P + h_1 = h_2 + w_P$; $q_P = 0$

Assume Pump is isentropic and the liquid is incompressible, Eq.7.18:

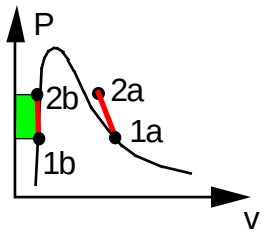
$w_{PS} = -\int v\, dP = -v_1(P_2 - P_1) = -0.01316\ (300 - 76.926)\ 144$

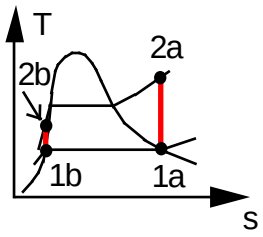
$= -422.73$ lbf-ft/lbm $= -0.543$ Btu/lbm

$h_2 = h_1 - w_P = 17.0 - (-0.543) = 17.543$ Btu/lbm,

Assume State 2 is approximately a saturated liquid => **$T_2 \cong 11.5$ F**

$\dot{W}_P = \dot{m} w_P = 1\ (-0.543)$ = **-0.543 Btu/s** = **-0.77 hp**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.200E

Liquid water at ambient conditions, 14.7 lbf/in.^{2}, 75 F, enters a pump at the rate of 1 lbm/s. Power input to the pump is 3 Btu/s. Assuming the pump process to be reversible, determine the pump exit pressure and temperature.

Solution:

C.V. Pump. Steady single inlet and exit flow with no heat transfer.

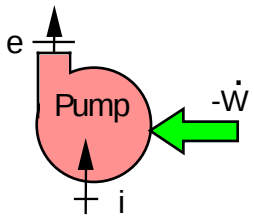
Energy Eq.4.13: $w = h_i - h_e = \dot{W}/\dot{m} = -3/1 = -3.0$ btu/lbm

Using also incompressible media we can use Eq.7.15

$$w_P = -\int vdP \approx -v_i(P_e - P_i) = -0.01606 \text{ ft/lbm}(P_e - 14.7 \text{ psia})$$

from which we can solve for the exit pressure

$$3 \cong 0.01606(P_e - 14.7) \times \frac{144}{778} \Rightarrow P_e = \mathbf{1023.9 \text{ lbf/in}^2}$$



$-\dot{W} = 3$ Btu/s, $P_i = 14.7$ psia

$T_i = 75$ F $\dot{m} = 1$ lbm/s

Energy Eq.: $h_e = h_i - w_P = 43.09 + 3 = 46.09$ Btu/lbm

Use Table F.7.3 at 1000 psia => $\mathbf{T_e = 75.3 \text{ F}}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.201E

The underwater bulb nose of a container ship has a velocity relative to the ocean water as 30 ft/s. What is the pressure at the front stagnation point that is 6 ft down from the water surface.

Solution:

C.V. A stream line of flow from the freestream to the wall.

Eq.7.17: $v(P_e - P_i) + \frac{1}{2}(\mathbf{V}_e^2 - \mathbf{V}_i^2) + g(Z_e - Z_i) = 0$

$$\Delta P = \frac{1}{2v}\mathbf{V}_i^2 = \frac{30^2}{0.01603 \times 32.174 \times 144 \times 2} = 6.06 \text{ psi}$$

$P_i = P_o + gH/v = 14.695 + 6/ (0.01603 \times 144) = 17.29$ psia

$P_e = P_i + \Delta P = 17.29 + 6.06 =$ **23.35 psia**

This container-ship is under construction and not loaded. The red line is the water line under normal load.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.202E

A speed boat has a small hole in the front of the drive with the propeller that sticks down into the water at a water depth of 15 in. Assume we have a stagnation point at that hole when the boat is sailing with 30 mi/h, what is the total pressure there?

Solution:

C.V. A stream line of flow from the freestream to the wall.

Eq.7.17: $v(P_e - P_i) + \frac{1}{2}(\mathbf{V}_e^2 - \mathbf{V}_i^2) + g(Z_e - Z_i) = 0$

$$\mathbf{V}_i = 30 \frac{\text{mi}}{\text{h}} \times 1.467 \frac{\text{ft-h}}{\text{s-mi}} = 44.01 \text{ ft/s}$$

$$\Delta P = \frac{1}{2v} \mathbf{V}_i^2 = \frac{44.01^2}{0.01603 \times 32.174 \times 144 \times 2} = 13.04 \text{ psi}$$

$$P_i = P_o + gH/v = 14.695 + \frac{15/12}{0.01603 \times 144} = 15.24 \text{ psia}$$

$$P_e = P_i + \Delta P = 15.24 + 13.04 = \mathbf{28.28 \text{ psia}}$$

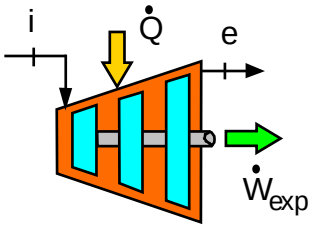
Remark: This is fast for a boat

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.203E

Helium gas enters a steady-flow expander at 120 lbf/in.^{2}, 500 F, and exits at 18 lbf/in.^{2}. The mass flow rate is 0.4 lbm/s, and the expansion process can be considered as a reversible polytropic process with exponent, n = 1.3. Calculate the power output of the expander.

Solution:



CV: expander, reversible polytropic process.
From Eq.6.28:

$$T_e = T_i \left(\frac{P_e}{P_i}\right)^{\frac{n-1}{n}} = 960 \left(\frac{18}{120}\right)^{\frac{0.3}{1.3}} = 619.6 \text{ R}$$

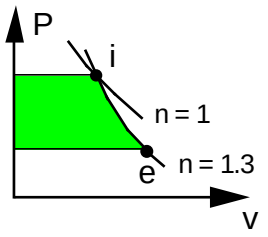
Table F.4: R = 386 lbf-ft/lbm-R

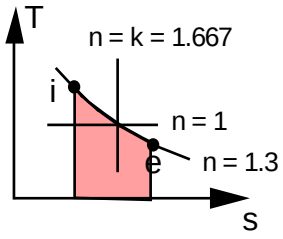
Work evaluated from Eq.7.18

$$w = -\int v dP = -\frac{nR}{n-1}(T_e - T_i) = -\frac{1.3 \times 386}{0.3 \times 778}(619.6 - 960)$$

$$= +731.8 \text{ Btu/lbm}$$

$$\dot{W} = \dot{m} w = 0.4 \times 731.8 \times \frac{3600}{2544} = \mathbf{414\ hp}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.204E

An expansion in a gas turbine can be approximated with a polytropic process with exponent n = 1.25. The inlet air is at 2100 R, 120 psia and the exit pressure is 18 psia with a mass flow rate of 2 lbm/s. Find the turbine heat transfer and power output.

Solution:

C.V. Steady state device, single inlet and single exit flow.

Energy Eq.4.13: $h_i + q = h_e + w$ Neglect kinetic, potential energies

Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e$

Process Eq.6.28:

$$T_e = T_i (P_e/ P_i)^{\frac{n-1}{n}} = 2100 \text{ R } (18/120)^{\frac{0.25}{1.25}} = 1436.9 \text{ R}$$

so the exit enthalpy is from Table F.5, $h_i = 532.6$ Btu/lbm

$$h_e = 343.0 + \frac{36.9}{40}(353.5 - 343.0) = 352.7 \text{ Btu/lbm}$$

The process leads to Eq.7.18 for the work term

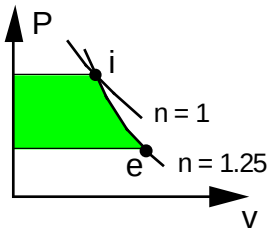
$$\dot{W} = \dot{m}w = -\dot{m}\frac{nR}{n-1}(T_e - T_i) = -2\,\frac{1.25 \times 53.34}{0.25 \times 778} \times (1436.9 - 2100)$$

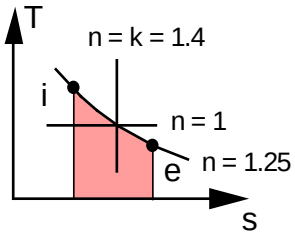
$$= \mathbf{454.6\ Btu/s}$$

Energy equation gives

$$\dot{Q} = \dot{m}q = \dot{m}(h_e - h_i) + \dot{W} = 2(352.7 - 532.6) + 454.6$$

$$= -359.8 + 454.6 = \mathbf{94.8\ Btu/s}$$





Notice:
dP < 0
so dw > 0

ds > 0
so dq > 0

Notice this process has some heat transfer in during expansion which is unusual. The typical process would have n = 1.5 with a heat loss.

Steady Irreversible Processes

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.205E

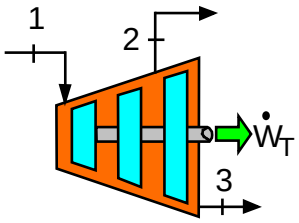
Analyse the steam turbine described in Problem 4.188E. Is it possible?

C.V. Turbine. Steady flow and adiabatic.

Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$;

Energy Eq.4.10: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3 + \dot{W}$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3$



States from Table F.7.2: $s_1 = 1.6398$ Btu/lbm R, $s_2 = 1.6516$ Btu/lbm R,

$$s_3 = s_f + x\, s_{fg} = 0.283 + 0.95 \times 1.5089 = 1.71 \text{ Btu/lbm R}$$

$$\dot{S}_{gen} = 40 \times 1.6516 + 160 \times 1.713 - 200 \times 1.6398 = \mathbf{12.2\ Btu/s \cdot R}$$

Since it is positive => possible.

Notice the entropy is increasing through turbine: $s_1 < s_2 < s_3$

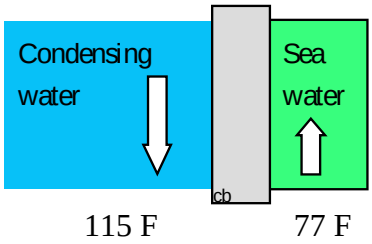
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.206E

A large condenser in a steam power plant dumps 15 000 Btu/s at 115 F with an ambient at 77 F. What is the entropy generation rate?
Solution:

This process transfers heat over a finite temperature difference between the water inside the condenser and the outside ambient (cooling water from the sea, lake or river or atmospheric air)

C.V. The wall that separates the inside 115 F water from the ambient at 77 F.



Entropy Eq. 7.1 for steady state operation:

$$\frac{dS}{dt} = 0 = \sum \frac{\dot{Q}}{T} + \dot{S}_{gen} = \frac{\dot{Q}}{T_{115}} - \frac{\dot{Q}}{T_{77}} + \dot{S}_{gen}$$

$$\dot{S}_{gen} = \left[\frac{15\,000}{536.7} - \frac{15\,000}{115 + 459.7} \right] \frac{Btu}{s\ R} = \mathbf{1.85}\ \frac{\mathbf{Btu}}{\mathbf{s\ R}}$$

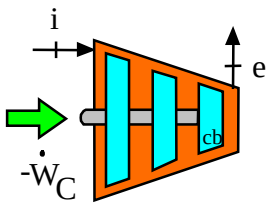
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.207E

A compressor in a commercial refrigerator receives R-410A at -10 F and x = 1. The exit is at 150 psia and 60 F. Is this compressor possible?

Solution:

C.V. Compressor, steady state, single inlet and exit flow. For this device we also assume no heat transfer and $Z_i = Z_e$



From Table F.9.1 : $h_i = 116.29$ Btu/lbm, $s_i = 0.2592$ Btu/lbm-R

From Table F.9.2 : $h_e = 124.58$ Btu/lbm, $s_e = 0.2508$ Btu/lbm-R

Entropy gives

$$s_{gen} = s_e - s_i - \int dq/T = 0.2508 - 0.2592 - \int dq/T =$$

The result is negative unless dq is negative (it should go out, but T < T ambient) so this compressor is **impossible**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.208E

R-134a at 90 F, 125 psia is throttled in a steady flow to a lower pressure so it comes out at 10 F. What is the specific entropy generation?

Solution:

The process is adiabatic and irreversible. The consideration of the energy given in example 6.5 resulted in a constant h and two-phase exit flow.

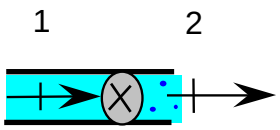
Table F.10.1: $h_i = 105.34$ Btu/lbm, $s_i = 0.2757$ Btu/lbm-R (compressed liquid)

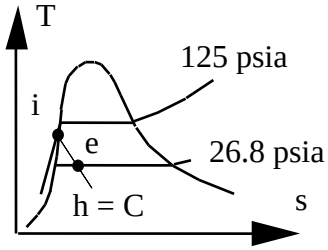
State 2: 10 F, $h_e = h_i < h_g$ so two-phase $x_e = (h_e - h_f)/h_{fg} = 0.2956$

Table F.10.1: $s_e = s_f + x_e\, s_{fg} = 0.2244 + 0.2956 \times 0.1896 = 0.2804$ Btu/lbm-R

We assumed no heat transfer so the entropy equation Eq.7.9 gives

$$s_{gen} = s_e - s_i - \int dq/T = 0.2804 - 0.2757 - 0 = \mathbf{0.0047\ Btu/lbm\text{-}R}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.209E

Two flowstreams of water, one at 100 lbf/in.^{2}, saturated vapor, and the other at 100 lbf/in.^{2}, 1000 F, mix adiabatically in a steady flow process to produce a single flow out at 100 lbf/in.2, 600 F. Find the total entropy generation for this process.

Solution:

Continuity Eq.4.9: $\dot{m}_3 = \dot{m}_1 + \dot{m}_2$,

Energy Eq.4.10: $\dot{m}_3 h_3 = \dot{m}_1 h_1 + \dot{m}_2 h_2$

State properties from Table F.7.2

$h_1 = 1187.8$, $h_2 = 1532.1$, $h_3 = 1329.3$ all in Btu/lbm

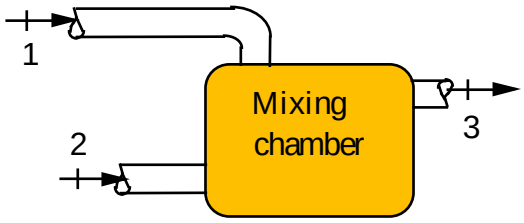
$s_1 = 1.6034$, $s_2 = 1.9204$, $s_3 = 1.7582$ all in Btu/lbm R

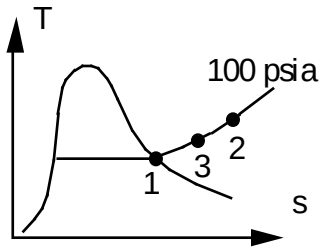
$$\Rightarrow \quad \dot{m}_1/\dot{m}_3 = (h_3 - h_2) / (h_1 - h_2) = 0.589$$

Entropy Eq.7.7: $\dot{m}_3 s_3 = \dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen}$ =>

$$\dot{S}_{gen}/\dot{m}_3 = s_3 - (\dot{m}_1/\dot{m}_3)\, s_1 - (\dot{m}_2/\dot{m}_3)\, s_2$$

$$= 1.7582 - 0.589 \times 1.6034 - 0.411 \times 1.9204 = \mathbf{0.0245}\ \frac{\mathbf{Btu}}{\mathbf{lbm\ R}}$$





The mixing process generates entropy. The two inlet flows could have exchanged energy (they have different T) through some heat engines and produced work, the process failed to do that, thus irreversible.

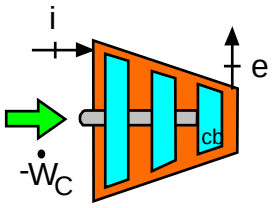
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.210E

A compressor in a commercial refrigerator receives R-410A at -10 F and x = 1. The exit is at 300 psia and 160 F. Neglect kinetic energies and find the specific entropy generation.

Solution:

C.V. Compressor, steady state, single inlet and exit flow. For this device we also assume no heat transfer q = 0 and $Z_1 = Z_2$



Entropy Eq.7.9: $s_i + \int dq/T + s_{gen} = s_e = s_i + 0 + s_{gen}$

From Table F.9.1 : $s_i = 0.2592$ Btu/lbm-R

From Table F.9.2 : $s_e = 0.2673$ Btu/lbm-R

Entropy generation becomes

$$s_{gen} = s_e - s_i = 0.2673 - 0.2592 = \mathbf{0.0081\ Btu/lbm\text{-}R}$$

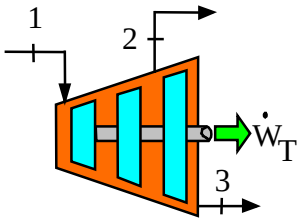
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.211E

A steam turbine has an inlet of 4 lbm/s water at 150 psia and 550 F with velocity of 50 ft/s. The exit is at 1 atm, 240 F and very low velocity. Find the power produced and the rate of entropy generation.

Solution:

C.V. Turbine. Steady flow and adiabatic.



Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2$;

Energy Eq.4.10: $\dot{m}_1(h_1 + \frac{1}{2}\mathbf{V}^2) = \dot{m}_2 h_2 + \dot{W}$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2$

States from Table F.7.2: $h_1 = 1300.05$ Btu/lbm, $s_1 = 1.6862$ Btu/lbm-R,

$h_2 = 1164.02$ Btu/lbm, $s_2 = 1.7764$ Btu/lbm-R

$$\dot{W} = \dot{m}_1(h_1 + \tfrac{1}{2}\mathbf{V}^2 - h_2) = 4\,(1300.05 + \tfrac{1}{2}\frac{50^2}{25037} - 1164.02) = \mathbf{546.1\ Btu/s}$$

$$\dot{S}_{gen} = \dot{m}_1(s_2 - s_1) = 4\,(1.7764 - 1.6862) = \mathbf{0.361\ Btu/s\text{-}R}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.212E

A dual fluid heat exchanger has 10 lbm/s water enter at 104 F, 20 psia and leaving at 50 F, 20 psia. The other fluid is glycol coming in at 14 F, 22 psia and leaves at 50 F, 22 psia. Find the mass flow rate of glycol and the rate of entropy generation.

Continuity Eqs.: Each line has a constant flow rate through it.

Energy Eq.4.10: $\dot{m}_{H_2O}\, h_1 + \dot{m}_{glycol}\, h_3 = \dot{m}_{H_2O}\, h_2 + \dot{m}_{glycol}\, h_4$

Entropy Eq.7.7: $0 = \dot{m}_{H_2O}\, s_1 + \dot{m}_{glycol}\, s_3 - \dot{m}_{H_2O}\, s_2 - \dot{m}_{glycol}\, s_4 + \dot{S}_{gen}$

Process: Each line has a constant pressure.

Table F.7: $h_1 = 72.03$, $h_2 = 18.05$ Btu/lbm, $s_1 = 0.1367$, $s_2 = 0.0361$ Btu/lbm-R

We could have used specific heat for the changes.

Table F.3: $C_{P\ gly} = 0.58$ Btu/lbm-R so

$$h_4 - h_3 = C_{P\ gly}(T_4 - T_3) = 0.58\ [50 - 14] = 20.88 \text{ Btu/lbm}$$

$$s_4 - s_3 = C_{P\ gly} \ln (T_4/T_3) = 0.58 \ln(509.7/473.7) = 0.0425 \text{ Btu/lbm-R}$$

$$\dot{m}_{glycol} = \dot{m}_{H_2O} \frac{h_1 - h_2}{h_4 - h_3} = 10\, \frac{72.03 - 18.05}{20.88} = \mathbf{25.85\ lbm/s}$$

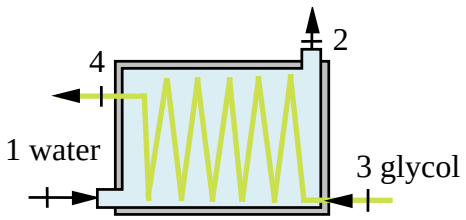
$$\dot{S}_{gen} = \dot{m}_{H_2O}\,(s_2 - s_1) + \dot{m}_{glycol}\,(s_4 - s_3)$$

$$= 10 \text{ lbm/s } (0.0361 - 0.1367) \text{ Btu/lbm-R}$$

$$+ 25.85 \text{ lbm/s} \times 0.0425 \text{ Btu/lbm-R}$$

$$= \mathbf{0.093\ Btu/s\text{-}R}$$

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for glycol and water each. The two flows exchange energy with no heat transfer to/from the outside.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.213E

A factory generates compressed air from ambient 15 psia, 62 F, by compression to 150 psia, 1080 R after which it cools in a constant pressure cooler to 540 R by heat transfer to the ambient. Find the specific entropy generation in the compressor and in the cooler operation.

Solution

C.V. air compressor $\dot{q} = 0$

Continuity Eq.: $\dot{m}_2 = \dot{m}_1$; Energy Eq.4.13: $0 = h_1 + w_{C\ in} - h_2$

Entropy Eq.: $0 = s_1 - s_2 + s_{gen\ comp}$

Table F.5 State 1: $h_1 = 124.79$ Btu/lbm, $s^o_{T1} = 1.63151$ Btu/lbm-R,

Table F.5 State 2: $h_2 = 261.099$ Btu/lbm, $s^o_{T2} = 1.80868$ Btu/lbm-R,

Table F.5 State 3: $h_3 = 129.18$ Btu/lbm, $s^o_{T3} = 1.63979$ Btu/lbm-R,

$$s_{gen\ comp} = s_2 - s_1 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1)$$

$$= 1.80868 - 1.63151 - \frac{53.34}{778} \ln(1000/100) = \mathbf{0.019\ Btu/lbmR}$$

C.V. cooler $w = 0$

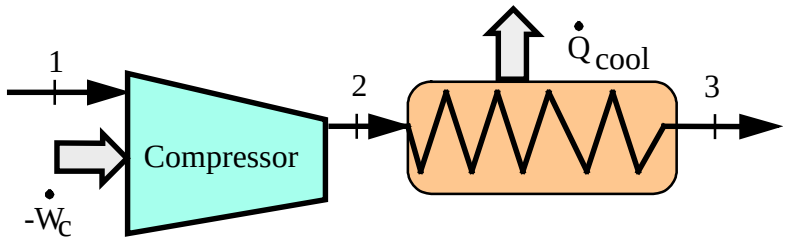
Continuity Eq.: $\dot{m}_3 = \dot{m}_1$; Energy Eq.4.13: $0 = h_2 - q_{out} - h_3$

Entropy Eq.: $0 = s_2 - s_3 - q_{out}/T_{amb} + s_{gen\ cool}$

$$q_{out} = h_2 - h_3 = 261.099 - 129.18 = 131.919 \text{ Btu/lbm}$$

$$s_{gen\ cool} = s_3 - s_2 + q_{out}/T_{amb} = s^o_{T3} - s^o_{T2} + q_{out}/T_{amb}$$

$$= 1.63979 - 1.80868 + \frac{131.919}{521.7} = \mathbf{0.084\ Btu/lbm}$$



Compressor section Cooler section

7.214E

A mixing chamber receives 10 lbm/min ammonia as saturated liquid at 0 F from one line and ammonia at 100 F, 40 lbf/in.^{2} from another line through a valve. The chamber also receives 340 Btu/min energy as heat transferred from a 100-F reservoir. This should produce saturated ammonia vapor at 0 F in the exit line. What is the mass flow rate at state 2 and what is the total entropy generation in the process?

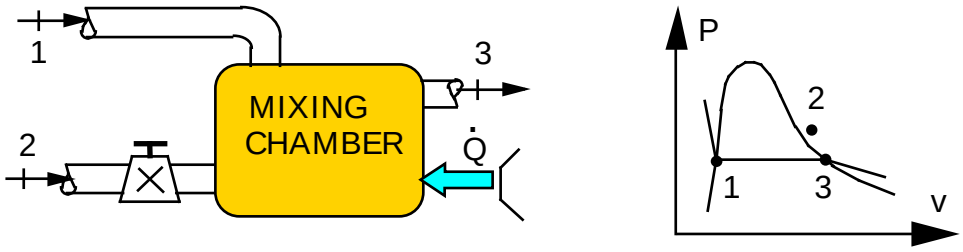
Solution:

CV: Mixing chamber out to reservoir

Continuity Eq.4.9: $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$

Energy Eq.4.10: $\dot{m}_1 h_1 + \dot{m}_2 h_2 + \dot{Q} = \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{Q}/T_{res} + \dot{S}_{gen} = \dot{m}_3 s_3$



From Table F.8.1: $h_1 = 42.6$ Btu/lbm, $s_1 = 0.0967$ Btu/lbm R

From Table F.8.2: $h_2 = 664.33$ Btu/lbm, $s_2 = 1.4074$ Btu/lbm R

From Table F.8.1: $h_3 = 610.92$ Btu/lbm, $s_3 = 1.3331$ Btu/lbm R

From the energy equation:

$$\dot{m}_2 = \frac{\dot{m}_1(h_1 - h_3) + \dot{Q}}{h_3 - h_2} = \frac{10(42.6 - 610.92) + 340}{610.92 - 664.33} = \mathbf{100.1\ lbm/min}$$

$$\Rightarrow \quad \dot{m}_3 = 110.1 \text{ lbm/min}$$

$$\dot{S}_{gen} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2 - \dot{Q}/T_{res}$$

$$= 110.1 \times 1.3331 - 10 \times 0.0967 - 100.1 \times 1.4074 - \frac{340}{559.67} = \mathbf{4.37}\ \frac{\mathbf{Btu}}{\mathbf{R\ min}}$$

7.215E

A condenser in a power plant receives 10 lbm/s steam at 130 F, quality 90% and rejects the heat to cooling water with an average temperature of 62 F. Find the power given to the cooling water in this constant pressure process and the total rate of enropy generation when condenser exit is saturated liquid.

Solution:

C.V. Condenser. Steady state with no shaft work term.

Energy Eq.4.12: $\dot{m}\, h_i + \dot{Q} = \dot{m} h_e$

Entropy Eq.7.8: $\dot{m}\, s_i + \dot{Q}/T + \dot{S}_{gen} = \dot{m}\, s_e$

Properties are from Table F.7.1

$h_i = 98.0 + 0.9 \times 1019.8 = 1015.8$ Btu/lbm, $h_e = 98.0$ Btu/lbm

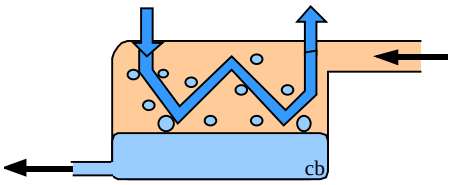
$s_i = 0.1817 + 0.9 \times 1.7292 = 1.7380$ Btu/lbm R, $s_e = 0.1817$ Btu/lbm R

$\dot{Q}_{out} = -\dot{Q} = \dot{m}\,(h_i - h_e) = 10(1015.8 - 98.0) =$ **9178 Btu/s**

$\dot{S}_{gen} = \dot{m}\,(s_e - s_i) + \dot{Q}_{out}/T$

$= 10(0.1817 - 1.738) + 9178/(459.7 + 62)$

$= -15.563 + 17.592 =$ **2.03 Btu/s-R**



Often the cooling media flows inside a long pipe carrying the energy away.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.216E

A large supply line has a steady flow of R-410A at 175 psia, 140 F. It is used in three different adiabatic devices shown in Fig. P7.101, a throttle flow, an ideal nozzle and an ideal turbine. All the exit flows are at 60 psia. Find the exit temperature and specific entropy generation for each device and the exit velocity of the nozzle.

Inlet state: F.9.2: $h_i = 143.11$ Btu/lbm, $s_i = 0.2804$ Btu/lbm-R

C.V. Throttle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e$ ($Z_i = Z_e$ and **V**'s are small)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + s_{gen}$

Exit state: $h_e = h_i = 143.11$ Btu/lbm, $T_e =$ **118.87 F,** $s_e = 0.3076$ kJ/kg-K

$s_{gen} = s_e - s_i = 0.3076 - 0.2804 =$ **0.0272 Btu/lbm-R**

C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2$ ($Z_i = Z_e$)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

The isentropic process ($s_e = s_i$) gives from F.9.2

$\mathbf{T_e = 49.15\ F}$, $\mathbf{s_{gen} = 0}$, $h_e = 128.36$ Btu/lbm

The energy equation becomes

$$\mathbf{V}_e^2/2 = h_i - h_e = 143.11 - 128.36 = 14.75 \text{ Btu/lbm}$$

$$\mathbf{V}_e = \sqrt{2 \times 14.75 \times 25037} = \mathbf{859\ ft/s}$$

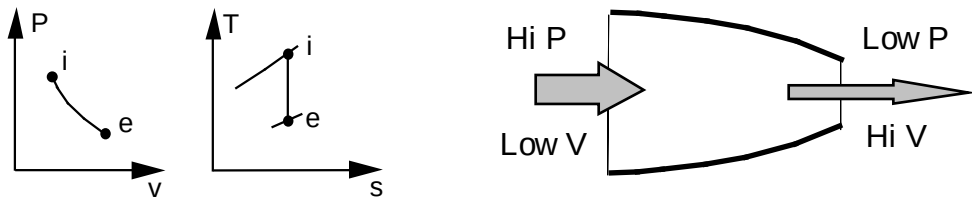
Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1

Turbine:

Process: Reversible and adiabatic => same as for nozzle except w, $\mathbf{V}_e = 0$

Energy Eq.4.13: $h_i = h_e + w$ ($Z_i = Z_e$)

$\mathbf{T_e = 49.15\ F}$, $\mathbf{s_{gen} = 0}$, $h_e = 128.36$ Btu/lbm



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.217E

Air at 540 F, 60 lbf/in.^{2} with a volume flow 40 ft^3/s runs through an adiabatic turbine with exhaust pressure of 15 lbf/in.^{2}. Neglect kinetic energies and use constant specific heats. Find the lowest and highest possible exit temperature. For each case find also the rate of work and the rate of entropy generation.

T_i = 540 F = 1000 R

$v_i = RT_i / P_i = 53.34 \times 1000/(60 \times 144) = 6.174$ ft^3 / lbm

$\dot{m} = \dot{V} / v_i = 40$ (ft^3/s) / 6.174 ft^3/ lbm = 6.479 lbm/s

a. **lowest exit T**, this must be reversible for maximum work out.

Process: Reversible and adiabatic => constant s from Eq.7.9

Eq.6.23: $T_e = T_i(P_e/P_i)^{\frac{k-1}{k}} = 1000$ R $(15/60)^{0.286} =$ **673 R**

w = 0.24 (1000 – 673) = 78.48 Btu/lbm ; $\dot{W} = \dot{m}w =$ **508.5 Btu/s**

$\dot{S}_{gen} =$ **0**

b. **Highest exit T**, for no work out. $T_e = T_i =$ **1000 R**

$\dot{W} =$ **0**

$\dot{S}_{gen} = \dot{m}(s_e - s_i) = -\dot{m}R \ln(P_e / P_i)$

$= -6.479 \times \frac{53.34}{778} \ln(15/60) =$ **0.616 Btu/s·R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.218E

A large supply line has a steady air flow at 900 R, 2 atm. It is used in three different adiabatic devices shown in Fig. P7.101, a throttle flow, an ideal nozzle and an ideal turbine. All the exit flows are at 1 atm. Find the exit temperature and specific entropy generation for each device and the exit velocity of the nozzle.

C.V. Throttle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e$ ($Z_i = Z_e$ and **V**'s are small)

Entropy Eq.7.8: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + s_{gen}$

Since it is air we have h = h(T) so same h means same $T_e = T_i =$ **900 R**

$$s_{gen} = s_e - s_i = s^o_{Te} - s^o_{Ti} - R \ln(P_e / P_i) = 0 - (53.34 / 778) \ln(1/2)$$
$$= \mathbf{0.0475\ Btu/lbm\text{-}R}$$

C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2$ ($Z_i = Z_e$)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

Use constant specific heat from Table F.4, $C_{Po} = 0.24$ Btu/lbm-R, k = 1.4

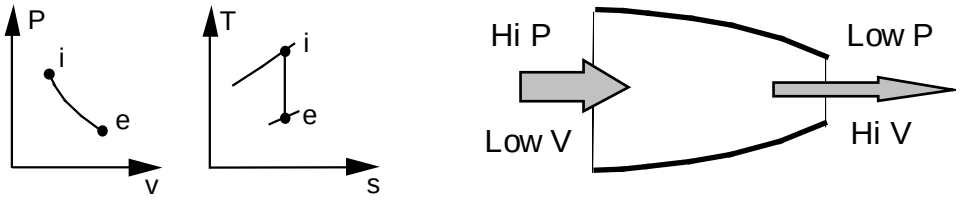
The isentropic process ($s_e = s_i$) gives Eq.6.23

$$\Rightarrow \quad T_e = T_i(P_e/P_i)^{\frac{k-1}{k}} = 900\ (1/2)^{0.2857} = \mathbf{738.3\ R}$$

The energy equation becomes: $\mathbf{V}_e^2/2 = h_i - h_e \cong C_P(T_i - T_e)$

$$\mathbf{V}_e = \sqrt{2\ C_P(T_i - T_e)} = \sqrt{2\times 0.24(900\text{-}738.3) \times 25037} = \mathbf{1394\ ft/s}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1



Turbine:

Process: Reversible and adiabatic => constant s from Eq.7.9

Eq.6.23: $T_e = T_i(P_e/P_i)^{\frac{k-1}{k}} = 900 \times (1/2)^{0.2857} =$ **738.3 R**

$$\Rightarrow \quad w = h_i - h_e = C_{Po}(T_i - T_e) = 0.24 \times (900 - 738.3) = 38.8\ \text{Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.219E

Repeat the previous problem for the throttle and the nozzle when the inlet air temperature is 4000 R and use the air tables.

C.V. Throttle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e$ ($Z_i = Z_e$ and **V**'s are small)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + s_{gen}$

Since it is air we have h = h(T) so same h means same $T_e = T_i =$ **4000 R**

$$s_{gen} = s_e - s_i = s^o_{Te} - s^o_{Ti} - R \ln(P_e / P_i) = 0 - (53.34 / 778) \ln(1/2)$$
$$= \mathbf{0.0475\ Btu/lbm\text{-}R}$$

C.V. Nozzle, Steady single inlet and exit flow, no work or heat transfer.

Energy Eq.4.13: $h_i = h_e + \mathbf{V}_e^2/2$ ($Z_i = Z_e$)

Entropy Eq.7.9: $s_e = s_i + \int dq/T + s_{gen} = s_i + 0 + 0$

The isentropic process ($s_e = s_i$) gives Eq.6.19

$$0 = s_e - s_i = s^o_{Te} - s^o_{Ti} - R \ln(P_e / P_i)$$

$$\Rightarrow \quad s^o_{Te} = s^o_{Ti} + R \ln(P_e / P_i) = 2.17221 + (53.34/778) \ln (1/2) = 2.12469$$

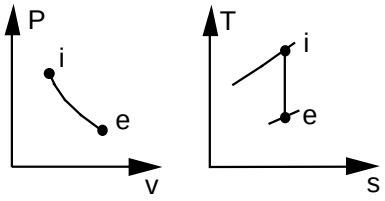
$T =$ **3846 R,** $h_e = 912.2$ Btu/lbm

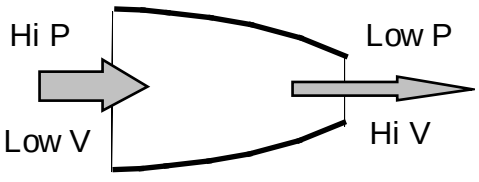
The energy equation becomes

$$\mathbf{V}_e^2/2 = h_i - h_e = 1087.988 - 912.2 = 175.79 \text{ Btu/lbm}$$

$$\mathbf{V}_e = \sqrt{2 \times 25\,037 \times 175.79} = \mathbf{2967\ ft/s}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.220E

A supply of 10 lbm/s ammonia at 80 lbf/in.^{2}, 80 F is needed. Two sources are available one is saturated liquid at 80 F and the other is at 80 lbf/in.^{2}, 260 F. Flows from the two sources are fed through valves to an insulated mixing chamber, which then produces the desired output state. Find the two source mass flow rates and the total rate of entropy generation by this setup.

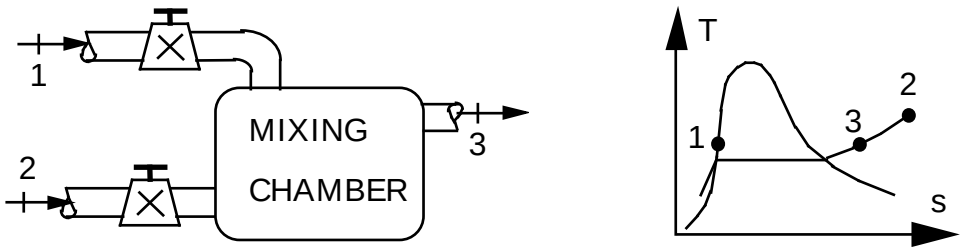
Solution:

C.V. mixing chamber + valve. Steady, no heat transfer, no work.

Continuity Eq.4.9: $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$;

Energy Eq.4.10: $\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen} = \dot{m}_3 s_3$



State 1: Table F.8.1 h_1 = 131.68 Btu/lbm, s_1= 0.2741 Btu/lbm R

State 2: Table F.8.2 h_2 = 748.5 Btu/lbm, s_2 = 1.4604 Btu/lbm R

State 3: Table F.8.2 h_3= 645.63 Btu/lbm, s_3= 1.2956 Btu/lbm R

As all states are known the energy equation establishes the ratio of mass flow rates and the entropy equation provides the entropy generation.

$$\dot{m}_1 h_1 + (\dot{m}_3 - \dot{m}_1) h_2 = \dot{m}_3 h_3 \Rightarrow \dot{m}_1 = \dot{m}_3 \frac{h_3 - h_2}{h_1 - h_2} = 10 \times \frac{-102.87}{-616.82} = 1.668 \text{ lbm/s}$$

$$\Rightarrow \quad \dot{m}_2 = \dot{m}_3 - \dot{m}_1 = 8.332 \text{ lbm/s}$$

$$\dot{S}_{gen} = \dot{m}_3 s_3 - \dot{m}_1 s_1 - \dot{m}_2 s_2$$

$$= 10 \times 1.2956 - 1.668 \times 0.2741 - 8.332 \times 1.46 = \mathbf{0.331\ Btu/s{\cdot}R}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.221E

An initially empty 5 ft^3 tank is filled with air from 70 F, 15 psia until it is full. Assume no heat transfer and find the final mass and entropy generation.

Solution:

C.V. Tank + valve out to line. No boundary/shaft work, $m_1 = 0$; Q = 0 and we recognize that this is a transient problem..

Continuity Eq.4.15: $m_2 - 0 = m_i$

Energy Eq.4.16: $m_2 u_2 - 0 = m_i h_i$

Entropy Eq.7.12: $m_2 s_2 - 0 = m_i s_i + 0 + {}_1S_{2\,gen}$

State 2: $P_2 = P_i$ and $u_2 = h_i = h_{line} = h_2 - RT_2$ (ideal gas)

To reduce or eliminate guess use: $h_2 - h_{line} = C_{Po}(T_2 - T_{line})$

Energy Eq. becomes: $C_{Po}(T_2 - T_{line}) - RT_2 = 0$

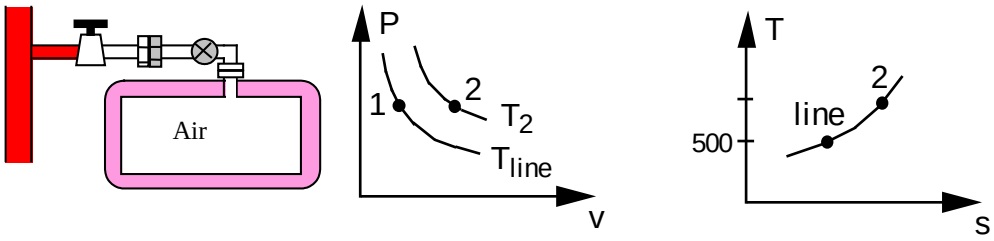
$$T_2 = T_{line}\, C_{Po}/(C_{Po} - R) = T_{line}\, C_{Po}/C_{Vo} = k\, T_{line}$$

Use F.4: $C_P = 0.24 \dfrac{\text{Btu}}{\text{lbm R}}$, k = 1.4 => $T_2 = 1.4 \times (70 + 460) =$ **742 R**

$$m_2 = P_2V/RT_2 = \frac{15 \text{ psia} \times 5 \text{ ft}^3 \times 144 \text{ (in/ft)}^2}{53.34 \text{ (ft lbf/lbm R)} \times 742 \text{R}} = \textbf{0.2729 lbm}$$

$${}_1S_{2\,gen} = m_2 (s_2 - s_i) = m_2[\, C_P \ln(T_2 / T_{line}) - R \ln(P_2 / P_{line})]$$

$$= 0.2729[0.24 \times \ln(1.4) - 0] = \textbf{0.351 Btu/R}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.222E

An empty cannister of volume 0.05 ft^3 is filled with R-134a from a line flowing saturated liquid R-134a at 40 F. The filling is done quickly so it is adiabatic. How much mass of R-134a is in the cannister? How much entropy was generated?

Solution:

C.V. Cannister filling process where: $_1Q_2 = 0$; $_1W_2 = 0$; $m_1 = 0$

Continuity Eq.4.15: $m_2 - 0 = m_{in}$;

Energy Eq.4.16: $m_2u_2 - 0 = m_{in}h_{line} + 0 + 0 \quad \Rightarrow \quad u_2 = h_{line}$

Entropy Eq.7.13: $m_2s_2 - 0 = m_{in}s_{line} + 0 + {}_1S_{2\,gen}$

Inlet state: Table F.10.1 $h_{line} = 88.56$ Btu/lbm, $s_{line} = 0.244$ Btu/lbm R

State 2: $P_2 = P_{line}$ and $u_2 = h_{line} = 88.56$ Btu/lbm > u_f

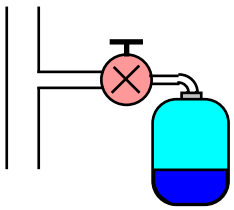
$$x_2 = \frac{u_2 - u_f}{u_{fg}} = \frac{88.56 - 88.45}{75.16} = 0.001464$$

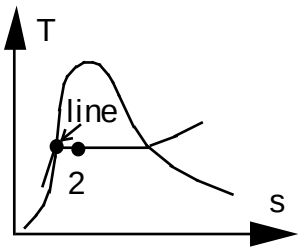
$v_2 = 0.01253 + x_2\ 0.9395 = 0.013905$ ft^3/lbm

$m_2 = V/v_2 = 0.05/0.013905 =$ **3.596 lbm**

$s_2 = 0.244 + x_2\ 0.1678 = 0.24425$ Btu/lbm R

$_1S_{2\,gen} = m_2(s_2 - s_{line}) = 3.596\ (0.24425 - 0.244) =$ **0.0009 Btu/R**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.223E

A can of volume 8 ft^3 is empty and filled with R-410A from a line at 200 psia, 100 F. The process is adiabatic and stops at P = 150 psia. Use Table F.9 to find the final temperature and the entropy generation.

Solution:

C.V. Cannister filling process where: $_1Q_2 = 0$; $_1W_2 = 0$; $m_1 = 0$

Continuity Eq.4.15: $m_2 - 0 = m_{in}$;

Energy Eq.4.16: $m_2u_2 - 0 = m_{in}h_{line} + 0 + 0 \Rightarrow u_2 = h_{line}$

Entropy Eq.7.12: $m_2s_2 - 0 = m_{in}s_{line} + {}_1S_{2\ gen}$

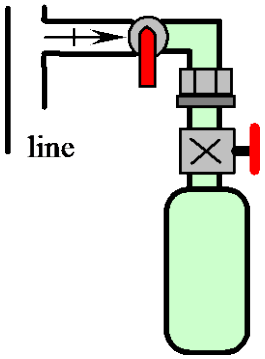
1: Table F.9.2 $h_{line} = 131.84$ Btu/lbm, $s_{line} = 0.2578$ Btu/lbm-R

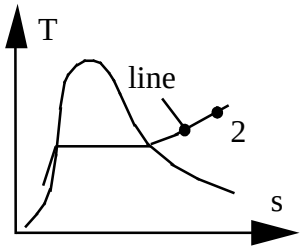
2: $P_2 = 150$ psia ; $u_2 = h_{line} \Rightarrow T_2 =$ **152.8 F**, $s_2 = 0.29084$ kJ/kg-K

$v_2 = 0.5515\ ft^3/lbm \Rightarrow m_2 = V/v_2 = 14.506$ lbm

$_1S_{2\ gen} = m_2s_2 - m_{in}s_{line} = m_2(s_2 - s_{line})$

$= 14.506\ (0.29084 - 0.2578) =$ **0.479 Btu/R**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.224E

Air from a line at 1800 lbf/in.^{2}, 60 F, flows into a 20-ft^3 rigid tank that initially contained air at ambient conditions, 14.7 lbf/in.^{2}, 60 F. The process occurs rapidly and is essentially adiabatic. The valve is closed when the pressure inside reaches some value, P_2. The tank eventually cools to room temperature, at which time the pressure inside is 750 lbf/in.^{2}. What is the pressure P_2? What is the net entropy change for the overall process?

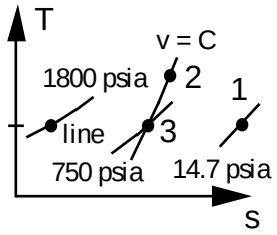
CV: Tank. Mass flows in, so this is transient. Find the mass first

$$m_1 = P_1V/RT_1 = \frac{14.7 \times 144 \times 20}{53.34 \times 520} = 1.526 \text{ lbm}$$

Fill to P_2, then cool to T_3 = 60 F, P_3 = 750 psia

$$m_3 = m_2 = P_3V/RT_3$$

$$= \frac{750 \times 144 \times 20}{53.34 \times 520} = 77.875 \text{ lbm}$$



Cont. Eq.: $m_i = m_2 - m_1 = 77.875 - 1.526 = 76.349$ lbm

The filling process from 1 to 2 ($T_1 = T_i$)

1-2 heat transfer = 0 so Energy Eq.: $m_ih_i = m_2u_2 - m_1u_1$

$$m_iC_{P0}T_i = m_2C_{V0}T_2 - m_1C_{V0}T_1$$

$$T_2 = \frac{76.349 \times 0.24 + 1.526 \times 0.171}{77.875 \times 0.171} \times 520 = 725.7 \text{ R}$$

$$P_2 = m_2RT_2/V = 77.875 \times 53.34 \times 725.7 / (144 \times 20) = \mathbf{1047 \text{ lbf/in}^2}$$

Consider the overall process from 1 to 3

Energy Eq.: $Q_{CV} + m_ih_i = m_2u_3 - m_1u_1 = m_2h_3 - m_1h_1 - (P_3 - P_1)V$

But, since $T_i = T_3 = T_1$, $m_ih_i = m_2h_3 - m_1h_1$

$\Rightarrow Q_{CV} = -(P_3 - P_1)V = -(750 - 14.7) \times 20 \times 144/778 = -2722$ Btu

From Eq.7.13 also Eqs.7.24-7.26

$$_1S_{2\,gen} = m_3s_3 - m_1s_1 - m_is_i - Q_{CV}/T_0 = m_3(s_3 - s_i) - m_1(s_1 - s_i) - Q_{CV}/T_0$$

$$= 77.875\left[0 - \frac{53.34}{778}\ln\left(\frac{750}{1800}\right)\right] - 1.526\left[0 - \frac{53.34}{778}\ln\left(\frac{14.7}{1800}\right)\right]$$

$$+ 2722/520 = \mathbf{9.406 \text{ Btu/R}}$$

Device Efficiency

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

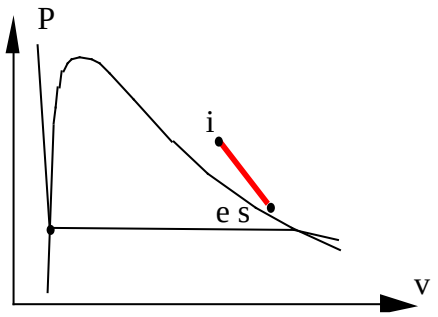
7.225E

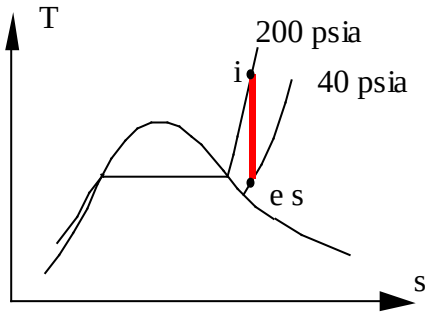
A steam turbine inlet is at 200 psia, 800 F. The exit is at 40 psia. What is the lowest possible exit temperature? Which efficiency does that correspond to?

We would expect the lowest possible exit temperature when the maximum amount of work is taken out. This happens in a reversible process so if we assume it is adiabatic this becomes an isentropic process.

Exit: 40 psia, $s = s_{in} = 1.7659$ Btu/lbm R $\Rightarrow$ **T = 409.6 F**

The efficiency from Eq.7.27 measures the turbine relative to an isentropic turbine, so the **efficiency** will be **100%**.





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

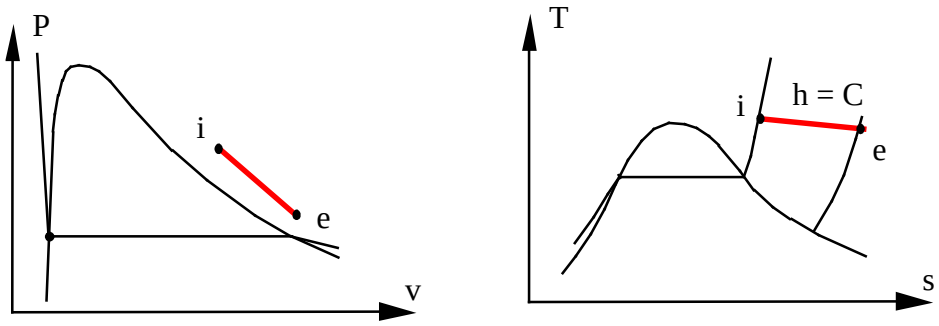
7.226E

A steam turbine inlet is at 200 psia, 800 F. The exit is at 40 psia. What is the highest possible exit temperature? Which efficiency does that correspond to?

The highest possible exit temperature would be if we did not get any work out, i.e. the turbine broke down. Now we have a throttle process with constant h assuming we do not have a significant exit velocity.

Exit: 40 psia, $h = h_{in} = 1425.31$ Btu/lbm $\Rightarrow$ **T = 786 F**

Efficiency: $\eta = \frac{w}{w_s} = \mathbf{0}$



Remark: Since process is irreversible there is no area under curve in T-s diagram that correspond to a q, nor is there any area in the P-v diagram corresponding to a shaft work.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.227E

A steam turbine inlet is at 200 psia, 800 F. The exit is at 40 psia, 600 F. What is the isentropic efficiency?

from table F.7.2

Inlet: h_{in} = 1425.31 Btu/lbm, s_{in} = 1.7659 Btu/lbm R

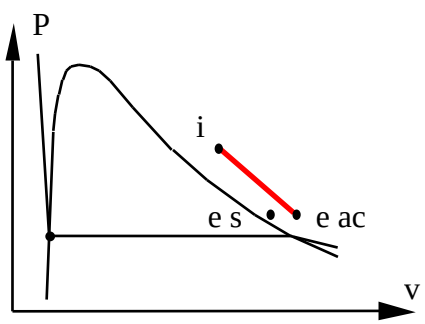
Exit: h_{ex} = 1333.43 Btu/lbm, s_{ex} = 1.8621 Btu/lbm R

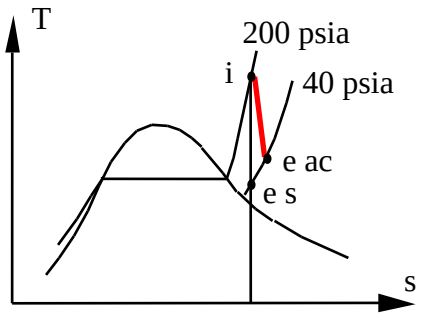
Ideal Exit: 40 psia, $s = s_{in}$ = 1.7659 Btu/lbm R $\Rightarrow$ h_s = 1241.05 Btu/lbm

$w_{ac} = h_{in} - h_{ex} = 1425.31 - 1333.43 = 91.88$ Btu/lbm

$w_s = h_{in} - h_s = 1425.31 - 1241.05 = 184.3$ Btu/lbm

$$\eta = \frac{w_{ac}}{w_s} = \frac{91.88}{184.3} = \mathbf{0.498}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.228E

The exit velocity of a nozzle is 1500 ft/s. If $\eta_{nozzle} = 0.88$ what is the ideal exit velocity?

The nozzle efficiency is given by Eq. 7.30 and since we have the actual exit velocity we get

$$\mathbf{V}_{e\,s}^2 = \mathbf{V}_{ac}^2/\eta_{nozzle} \quad \Rightarrow$$

$$\mathbf{V}_{e\,s} = \mathbf{V}_{ac}/\sqrt{\eta_{nozzle}} = 1500 \text{ (ft/s)} / \sqrt{0.88} = \mathbf{1599\ ft/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.229E

A small air turbine with an isentropic efficiency of 80% should produce 120 Btu/lbm of work. The inlet temperature is 1800 R and it exhausts to the atmosphere. Find the required inlet pressure and the exhaust temperature.

Solution:

C.V. Turbine actual energy Eq.4.13:

$$w = h_i - h_{e,ac} = 120$$

Table F.5: $h_i = 449.794$ Btu/lbm

$$\Rightarrow \quad h_{e,ac} = h_i - 120 = 329.794 \text{ Btu/lbm}, \quad \mathbf{T_e = 1349\ R}$$

C.V. Ideal turbine, Eq.7.27 and energy Eq.4.13:

$$w_s = w/\eta_s = 120/0.8 = 150 = h_i - h_{e,s} \quad \Rightarrow \quad h_{e,s} = 299.794 \text{ Btu/lbm}$$

From Table F.5: $T_{e,s} = 1232.7$ R, $s^o_{Te} = 1.84217$ Btu/lbm R

Entropy Eq.7.9: $s_i = s_{e,s}$ adiabatic and reversible

To relate the entropy to the pressure use Eq.6.19 inverted and standard entropy from Table F.5:

$$P_e/P_i = \exp[\,(s^o_{Te} - s^o_{Ti})/R\,] = \exp[(1.84217 - 1.94209)\frac{778}{53.34}] = 0.2328$$

$$P_i = P_e / 0.2328 = 14.7/0.2328 = \mathbf{63.14\ psia}$$

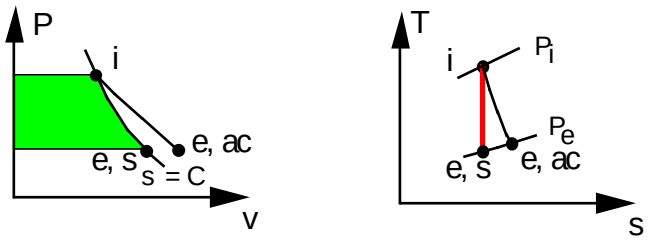
If constant heat capacity was used

$$T_e = T_i - w/C_p = 1800 - 120/0.24 = 1300 \text{ R}$$

$$T_{e,s} = T_i - w_s/C_p = 1800 - 150/0.24 = 1175 \text{ R}$$

Eq.7.9 (adibatic and reversible) gives constant s and relation is Eq.6.23

$$P_e/P_i = (T_e/T_i)^{k/(k-1)} \quad \Rightarrow \quad P_i = 14.7\ (1800/1175)^{3.5} = 65.4 \text{ psia}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.230E

Redo Problem 7.198 if the water pump has an isentropic efficiency of 85% (hose, nozzle included).

Solution:

C.V.: pump + hose + water column, total height difference 110 ft. Here **V** is velocity, not volume.

Continuity Eq.4.3, 4.11: $\dot{m}_{in} = \dot{m}_{ex} = (\rho A \mathbf{V})_{nozzle}$

Energy Eq.4.12: $\dot{m}(-w_p) + \dot{m}(h + \mathbf{V}^2/2 + gz)_{in} = \dot{m}(h + \mathbf{V}^2/2 + gz)_{ex}$

Process: $h_{in} \cong h_{ex}$, $\mathbf{V}_{in} \cong \mathbf{V}_{ex} = 0$, $z_{ex} - z_{in} = 110$ ft, $\rho = 1/v \cong 1/v_f$

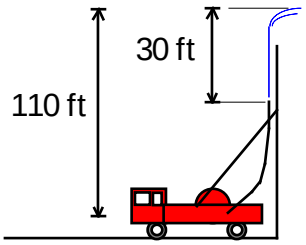
$$-w_p = g(z_{ex} - z_{in}) = 32.174 \times (110 - 0)/25\,037 = 0.141 \text{ Btu/lbm}$$

Recall the conversion 1 Btu/lbm = 25 037 ft^2/s^2 from Table A.1. The velocity in the exit nozzle is such that it can rise 30 ft. Make that column a C.V. for which Bernoulli Eq.7.17 is:

$$gz_{noz} + \frac{1}{2}\mathbf{V}^2_{noz} = gz_{ex} + 0$$

$$\mathbf{V}_{noz} = \sqrt{2g(z_{ex} - z_{noz})}$$

$$= \sqrt{2 \times 32.174 \times 30} = 43.94 \text{ ft/s}$$



Assume: $v = v_{F,70F} = 0.01605$ ft^3/lbm

$$\dot{m} = \frac{\pi}{v_f}\left(\frac{D}{2}\right)^2 \mathbf{V}_{noz} = (\pi/4)\,(1^2/144) \times 43.94 / 0.01605 = 14.92 \text{ lbm/s}$$

$$\dot{W}_{pump} = \dot{m} w_p/\eta = 14.92 \times 0.141 \times (3600/2544)/0.85 = \mathbf{3.5\ hp}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.231E

Air enters an insulated compressor at ambient conditions, 14.7 lbf/in.^{2}, 70 F, at the rate of 0.1 lbm/s and exits at 400 F. The isentropic efficiency of the compressor is 70%. What is the exit pressure? How much power is required to drive the compressor?

Solution:

C.V. Compressor: P_1, T_1, T_e(real), $\eta_{s\,COMP}$ known, assume constant C_{P0}

Energy Eq.4.13 for real: $-w = C_{P0}(T_e - T_i) = 0.24(400 - 70) = 79.2$ Btu/lbm

Ideal $-w_s = -w \times \eta_s = 79.2 \times 0.7 = 55.4$ Btu/lbm

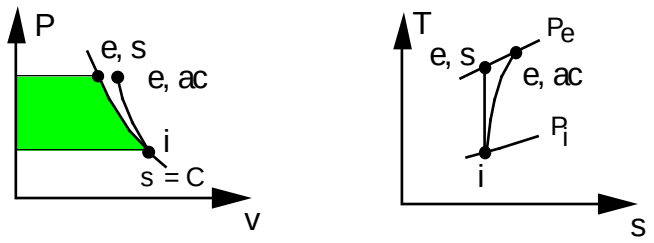
Energy Eq.4.13 for ideal:

$55.4 = C_{P0}(T_{es} - T_i) = 0.24(T_{es} - 530)$, $T_{es} = 761$ R

Constant entropy for ideal as in Eq.6.23:

$$P_e = P_i(T_{es}/T_i)^{\frac{k}{k-1}} = 14.7(761/530)^{3.5} = \mathbf{52.1\ lbf/in^2}$$

$$-\dot{W}_{REAL} = \dot{m}(-w) = 0.1 \times 79.2 \times 3600/2544 = \mathbf{11.2\ hp}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.232E

A nozzle is required to produce a steady stream of R-134a at 790 ft/s at ambient conditions, 15 lbf/in.^{2}, 70 F. The isentropic efficiency may be assumed to be 90%. What pressure and temperature are required in the line upstream of the nozzle?

C.V. Nozzle, steady flow and no heat transfer.

Actual nozzle energy Eq.: $h_1 = h_2 + \mathbf{V}_2^2/2$

State 2 actual: Table F.10.2 $h_2 = 180.975$ Btu/lbm

$$h_1 = h_2 + \mathbf{V}_2^2/2 = 180.975 + \frac{790^2}{2 \times 25\,037} = 193.44 \text{ Btu/lbm}$$

Recall 1 Btu/lbm = 25 037 ft^2/s^2 from Table A.1.

Ideal nozzle exit: $h_{2s} = h_1 - KE_s = 193.44 - \frac{790^2}{2 \times 25\,037}/0.9 = 179.59$ Btu/lbm

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 from A.1

State 2s: $(P_2, h_{2s}) \Rightarrow T_{2s} = 63.16$ F, $s_{2s} = 0.4481$ Btu/lbm R

Entropy Eq. ideal nozzle: $s_1 = s_{2s}$

State 1: $(h_1, s_1 = s_{2s}) \Rightarrow$ Double interpolation or use software.

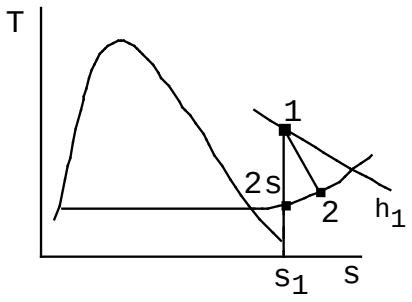
For 40 psia: given h_1 then $s = 0.4544$ Btu/lbm R, $T = 134.47$ F

For 60 psia: given h_1 then $s = 0.4469$ Btu/lbm R, $T = 138.13$ F

Now a linear interpolation to get P and T for proper s

$$P_1 = 40 + 20\,\frac{0.4481 - 0.4544}{0.4469 - 0.4544} = \mathbf{56.8 \text{ psia}}$$

$$T_1 = 134.47 + (138.13 - 134.47)\frac{0.4481 - 0.4544}{0.4469 - 0.4544} = \mathbf{137.5 \text{ F}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Review Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.233E

A watercooled air compressor takes air in at 70 F, 14 lbf/in.^{2} and compresses it to 80 lbf/in.^{2}. The isothermal efficiency is 88% and the actual compressor has the same heat transfer as the ideal one. Find the specific compressor work and the exit temperature.

Solution:

Ideal isothermal compressor exit 80 psia, 70 F

Reversible process: $dq = T\,ds \quad \Rightarrow \quad q = T(s_e - s_i)$

$$q = T(s_e - s_i) = T[s^o_{Te} - s^o_{T1} - R \ln(P_e / P_i)]$$

$$= - RT \ln (P_e / P_i) = - (460 + 70) \frac{53.34}{778} \ln \frac{80}{14} = - 63.3 \text{ Btu/lbm}$$

As same temperature for the ideal compressor $h_e = h_i \Rightarrow$

$w = q = -63.3$ Btu/lbm $\Rightarrow$ $w_{ac} = w/\eta =$ **- 71.93 Btu/lbm**, $q_{ac} = q$

Now for the actual compressor energy equation becomes

$$q_{ac} + h_i = h_{e\,ac} + w_{ac} \Rightarrow$$

$$h_{e\,ac} - h_i = q_{ac} - w_{ac} = - 63.3 - (-71.93) = 8.63 \text{ Btu/lbm} \approx C_p (T_{e\,ac} - T_i)$$

$$T_{e\,ac} = T_i + 8.63/0.24 = \mathbf{105.9\ F}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.234E

Repeat Problem 7.199 for a pump/compressor isentropic efficiency of 70%.

Solution:

C.V.: Pump/Compressor, $\dot{m}$ = 1 lbm/s, R-410A

a) State 1: Table F.9.1, $x_1 = 1.0$ Saturated vapor, $P_1 = P_g = 76.926$ psia,
$h_1 = h_g = 118.21$ Btu/lbm, $s_1 = s_g = 0.2535$ Btu/lbm R

Ideal Compressor is isentropic, $s_2 = s_1 = 0.2535$ Btu/lbm R

$h_2 = 134.54$ Btu/lbm, $T_2 = 130.5$ F

Energy Eq.4.13: $q_C + h_1 = h_2 + w_C$; $q_C = 0$

$w_{CS} = h_1 - h_2 = 118.21 - 134.54 = -16.33$ Btu/lbm;

Now the actual compressor

$w_{C,\,AC} = w_{CS}/\eta = -23.33 = h_1 - h_{2\,AC}$

$h_{2,\,AC} = 134.54 + 23.33 = 157.87 \Rightarrow T_2 =$ **217 F**

=> $\dot{W}_{C\,in} = \dot{m}(-w_C) =$ **23.3 Btu/s = 33 hp**

b) State 1: $T_1 = 10$ F, $x_1 = 0$ Saturated liquid. This is a pump.

$P_1 = 76.926$ psia, $h_1 = h_f = 17.0$ Btu/lbm, $v_1 = v_f = 0.01316$ ft^3/lbm

Energy Eq.4.13: $q_P + h_1 = h_2 + w_P$; $q_P = 0$

Ideal pump is isentropic and the liquid is incompressible, Eq.7.18:

$w_{PS} = -\int v\,dP = -v_1(P_2 - P_1) = -0.01316\,(300 - 76.926)\,144$

$= -422.73$ lbf-ft/lbm $= -0.543$ Btu/lbm

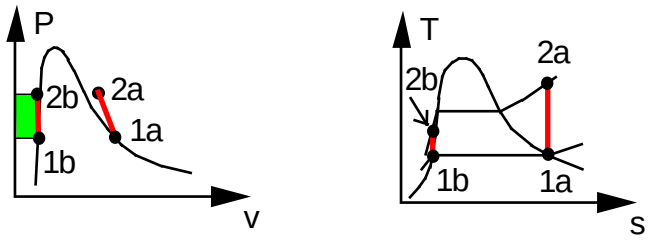
Now the actual pump

$w_{C,\,AC} = w_{CS}/\eta = -0.776 = h_1 - h_{2\,AC}$

$h_2 = h_1 - w_P = 17.0 - (-0.776) = 17.776$ Btu/lbm,

Assume State 2 is approximately a saturated liquid => $T_2 \cong$ **12.2 F**

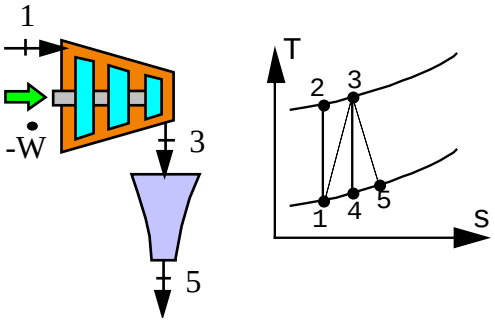
$\dot{W}_{P\,in} = \dot{m}(-w_P) = 1\,(0.776) =$ **0.776 Btu/s** = **0.99 hp**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.235E

Air at 1 atm, 60 F is compressed to 4 atm, after which it is expanded through a nozzle back to the atmosphere. The compressor and the nozzle both have efficiency of 90% and kinetic energy in/out of the compressor can be neglected. Find the actual compressor work and its exit temperature and find the actual nozzle exit velocity.



Steady state separate control volumes around compressor and nozzle. For ideal compressor we have inlet : 1 and exit : 2

Adiabatic : $q = 0$.

Reversible: $s_{gen} = 0$

Energy Eq.: $h_1 + 0 = w_C + h_2$;

Entropy Eq.: $s_1 + 0/T + 0 = s_2$

Ideal compressor: $w_c = h_1 - h_2$, $s_2 = s_1$

The constant s from Eq. 6.23 gives

$$T_2 = T_1 (P_2/P_1)^{\frac{k-1}{k}} = (459.7 + 60)\ R \times (4/1)^{0.2857} = 772\ R$$

$$\Rightarrow \quad -w_C = h_2 - h_1 = C_P(T_2 - T_1) = 0.24\ (772 - 519.7) = 60.55\ Btu/lbm$$

Actual compressor: $w_{c,AC} = w_{c,s}/\eta_c =$ **-67.3 Btu/lbm** $= h_1 - h_3$

$$\Rightarrow \quad T_3 = T_1 - w_{c,AC}/C_P = 519.7 + 67.3/0.24 = \mathbf{800\ R}$$

Ideal nozzle: $s_4 = s_3$ so use Eq.6.23 again

$$\Rightarrow \quad T_4 = T_3 \times (P_4/P_3)^{\frac{k-1}{k}} = 800\ (1/4)^{0.2857} = 538.4\ R$$

$$\mathbf{V}_s^2/2 = h_3 - h_4 = C_P(T_3 - T_4) = 0.24(800 - 538.4) = 62.78\ Btu/lbm$$

$$\mathbf{V}_{AC}^2/2 = \mathbf{V}_s^2 \times \eta_{NOZ}/2 = 62.78 \times 0.9 = 56.5\ Btu/lbm$$

$$\mathbf{V}_{AC} = \sqrt{2 \times 56.5 \times 25\,037} = \mathbf{1682\ ft/s}$$

Remember conversion 1 Btu/lbm = 25 037 ft^2/s^2 from Table A.1.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

7.236E

A rigid 35 ft^3 tank contains water initially at 250 F, with 50 % liquid and 50% vapor, by volume. A pressure-relief valve on the top of the tank is set to 150 lbf/in.^{2} (the tank pressure cannot exceed 150 lbf/in.^{2} - water will be discharged instead). Heat is now transferred to the tank from a 400 F heat source until the tank contains saturated vapor at 150 lbf/in.^{2}. Calculate the heat transfer to the tank and show that this process does not violate the second law.

C.V. Tank and walls out to the source. Neglect storage in walls. There is flow out and no boundary or shaft work.

Continuity Eq.4.15: $m_2 - m_1 = - m_e$

Energy Eq.4.16: $m_2 u_2 - m_1 u_1 = - m_e h_e + {}_1Q_2$

Entropy Eq.7.12: $m_2 s_2 - m_1 s_1 = - m_e s_e + \int dQ/T + {}_1S_{2\,gen}$

State 1: 250 F, Table F.7.1 $v_{f1} = 0.017$, $v_{g1} = 13.8247$ ft^3/lbm

$m_{LIQ} = V_{LIQ} / v_{f1} = 0.5 \times 35/0.017 = 1029.4$ lbm

$m_{VAP} = V_{VAP} / v_{g1} = 0.5 \times 35/13.8247 = 1.266$ lbm

$m = 1030.67$ lbm

$x = m_{VAP} / (m_{LIQ} + m_{VAP}) = 0.001228$

$u = u_{f1} + x\ u_{fg1} = 218.48 + 0.001228 \times 869.41 = 219.55$

$s = s_{f1} + x\ s_{fg1} = 0.3677 + 0.001228 \times 1.3324 = 0.36934$

state 2: $v_2 = v_g = 3.2214$ ft^3/lbm, $u_2 = 1110.31$, $h_2 = 1193.77$ Btu/lbm

$s_2 = 1.576$ Btu/lbm-R $m_2 = V/v_2 = 10.865$ lbm

From the energy equation we get

$${}_1Q_2 = m_2 u_2 - m_1 u_1 + m_e h_e$$

$$= 10.865 \times 1110.31 - 1030.67 \times 219.55 + 1019.8 \times 1193.77$$

$$= 1\ 003\ 187 \text{ Btu}$$

$${}_1S_{2\,gen} = m_2 s_2 - m_1 s_1 - m_e s_e - {}_1Q_2 / T_{source}$$

$$= 10.865 \times 1.576 - 1030.67 \times 0.36934 + 1019.8 \times 1.57 - 1003187/860$$

$$= \mathbf{77.2\ Btu/R}$$

8.a

Can I have any energy transfer as heat transfer that is 100% available?

By definition the possible amount of work that can be obtained equals the exergy. The maximum is limited to that out of a reversible heat engine, if constant T then that is the Carnot heat engine

$$W = (1 - \frac{T_O}{T})Q$$

So we get a maximum for an infinite high temperature T, where we approach an efficiency of one. In practice you do not have such a source (the closest would be solar radiation) and secondly no material could contain matter at very high T so a cycle process can proceed (the closest would be a plasma suspended by a magnetic field as in a tokamak).

8.b

Is electrical work 100% available?

Yes. By definition work is 100% exergy.

8.c

A nozzle does not have any actual work involved, how should you then interpret the reversible work?

The purpose of the nozzle is not to make work, but the reversible work can be used to generate kinetic energy in addition to what comes out of the actual nozzle. The reversible work plus the actual kinetic energy would equal the possible total kinetic energy out of the reversible nozzle. The other point is that the reversible nozzle has a heat transfer in (if the actual nozzle is irreversible) also unusual for a nozzle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.d

If an actual control volume process is reversible what can you say about the work term?

The work term is the maximum possible. If the work is positive it is the maximum possible work out and if the work is negative it is the minimum work possible that must be supplied.

8.e

Can entropy change in a control volume process that is reversible?

Yes it can. A flow in or out at a state with a different entropy than the average entropy inside or a heat transfer will change the entropy. All the terms that changes the entropy are transfer terms so there is no net increase (generation) of entropy.

8.f

Energy can be stored as internal energy, potential energy or kinetic energy. Are those energy forms all 100% available?

The internal energy is only partly available, a process like an expansion can give out work or if it cools by heat transfer out it is a Q out that is only partly available as work. Potential energy like from gravitation, mgH, or a compressed spring or a charged battery are forms that are close to 100% available with only small losses present. Kinetic energy like in a fly-wheel or motion of a mass can be transferred to work out with losses depending on the mechanical system.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.g

We cannot create nor destroy energy, can we create or destroy exergy?

Yes. Every process that is irreversible to some degree destroys exergy. This destruction is directly proportional to the entropy generation. We cannot create exergy at most it can stay constant, which is the case for a reversible process.

8.h

In a turbine what is the source of exergy?

The flow into the turbine is the source, it provides the conditions that allows the turbine to give work out. If the turbine exit flow has useful exergy we can write the net source as the inlet flow exergy minus the exit flow exergy

8.i

In a pump what is the source of exergy?

The shaft work is the input that drives the pump, which in turn pushes on the flow to generate a higher pressure exit flow. The increase in the flow exergy is the desired output, that is expressing the increase in P in terms of exergy.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.j

In a pump what gains exergy?

The higher pressure exit flow is the desired output. When we express that in terms of exergy it becomes the increase in the flow exergy that is the output, that is expressing the increase in P in terms of exergy.

8.k

In a heat engine what is the source of exergy?

Generally it is the high temperature heat transfer. However, if the rejected heat transfer at the low temperature has any useful exergy we can also count the difference as the source.

8.l

In a heat pump what is the source of exergy?

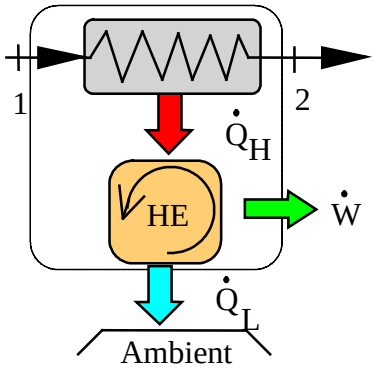
The work input is what drives the heat pump.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.m

In Eq.8.39 for the heat engine the source of exergy was written as a heat transfer. How does the expression look like if the source is a flow of hot gas being cooled down as it gives energy to the heat engine?

Look at a heat exchanger that provides such a set-up in Fig. 8.3



C.V. Heat exchanger plus H.E.

Energy Eq.6.12:

$$0 = \dot{m}_1 h_1 - \dot{m}_1 h_2 - \dot{W} - \dot{Q}_L$$

Entropy Eq.7.2:

$$0 = \dot{m}_1 s_1 - \dot{m}_1 s_2 - \dot{Q}_L/T_o + \dot{S}_{gen}$$

Solve for $\dot{Q}_L$ and sustitute into energy Eq.

$$\dot{Q}_L = T_o \dot{m}_1 (s_1 - s_2) + T_o \dot{S}_{gen}$$

$$\dot{W} = \dot{m}_1 [\, h_1 - h_2 - T_o (s_1 - s_2)] - T_o \dot{S}_{gen}$$

$$= \dot{m}_1 (\psi_1 - \psi_2) - T_o \dot{S}_{gen}$$

$$= \eta_{HE\ II}\ \dot{m}_1 (\psi_1 - \psi_2) = \eta_{HE\ II}\ \dot{W}^{rev}$$

So the H.E. work is a fraction of the flow exergy.

Concept-Study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.1

Why does the reversible C.V. counterpart to the actual C.V. have the same storage and flow terms?

If you want to compare two devices they should be comparable in as many respects as possible to be useful. Specifically when we want to find the possible work output all the aspects that can generate work are important and must be considered. The flows in and out and the storage effect are closely tied to the possible work output and thus should be the same for the two control volumes. Obviously one control volume that receives a high exergy flow or depletes its stored exergy can give out more work than a control volume that does not have such effects.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.2

Can one of the heat transfers in Eq.8.5-6 be to or from the ambient?

Yes it can, then the reversible heat transfer we find from the ambient to balance the entropy is in addition to the one already listed. In many practical devices there is an actual heat transfer loss to the surroundings because of elevated temperatures inside the device.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.3

All the energy in the ocean is that available?

No. Since the ocean is at the ambient T (it **is** the ambient) it is not possible to extract any work from it. You can extract wave energy (wind generated kinetic energy) or run turbines from the tide flow of water (moon generated kinetic energy). However, since the ocean temperature is not uniform there are a few locations where cold and warmer water flows close to each other like at different depths. In that case a heat engine can operate due to the temperature difference.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.4

Does a reversible process change the exergy if there is no work involved?

Yes. There can be heat transfer involved and that has an exergy associated with it, which then equals the change of exergy of the substance. A flow can enter and exit a device with different levels of exergy. What is unchanged is the total (CV plus surroundings) exergy that remains constant, but it may be redistributed.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.5

Is the reversible work between two states the same as ideal work for the device?

No. It depends on the definition of ideal work. The ideal device does not necessarily have the same exit state as the actual device. An ideal turbine is approximated as a reversible adiabatic device so the ideal work is the isentropic work. The reversible work is between the inlet state and the actual exit state that do not necessarily have the same entropy.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.6

When is the reversible work the same as the isentropic work?

That happens when the inlet and exit states (or beginning and end states) have the same entropy. For a reversible adiabatic process in a C.V (which then is isentropic) the two work terms become the same.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.7

If I heat some cold liquid water to T_o, do I increase its exergy?

No. You decrease its exergy by bringing it closer to T_o, where it has zero exergy, if we neglect pressure effects. Any substance at a T different from ambient (higher or lower) has a positive exergy since you can run a heat engine using the two temperatures as the hot and cold reservoir, respectively. For a T lower than the ambient it means that the ambient is the hot side of the heat engine.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.8

Are reversible work and exergy connected?

Yes. They are very similar. Reversible work is usually defined as the reversible work that can be obtained between two states, inlet-exit or beginning to end. Exergy is a property of a given state and defined as the reversible work that can be obtained by changing the state of the substance from the given state to the dead state (ambient).

The only difference is the work term exchanged with the ambient if the control volume changes its volume, $W = P_o \Delta V$.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.9

Consider exergy associated with a flow. The total exergy is based on the thermodynamic state, the kinetic and potential energies. Can they all be negative?

No. By virtue of its definition kinetic energy can only be positive. The potential energy is measured from a reference elevation (standard sea level or a local elevation) so it can be negative. The thermodynamic state can only have a positive exergy the smallest it can be is zero if it is the ambient dead state.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.10

Verify that Eq.8.29 reduces to Eq.8.14 for a steady state process

The expression for the reversible work is

$$\dot{W}^{rev} = \dot{\Phi}_q + \sum \dot{m}_i \, \psi_i - \sum \dot{m}_e \, \psi_e - \dot{\Phi}_{CV} + P_o \, \dot{V} \qquad (10.29)$$

Definition of steady state is no storage effect so:

$$\dot{V} = 0; \qquad \dot{\Phi}_{CV} = 0$$

the last two terms in Eq.8.29 drop out. Eq.8.14 is also written for a single flow so the summations are each a single term.

$$\sum \dot{m}_i \, \psi_i - \sum \dot{m}_e \, \psi_e = \dot{m} \, \psi_i - \dot{m} \, \psi_e = \dot{m} \, (\psi_i - \psi_e)$$

The heat transfer term is from Eq.8.21 and with single flow

$$\dot{\Phi}_q = \sum (1 - \frac{T_o}{T_j}) \, \dot{Q}_j = \dot{m} \sum (1 - \frac{T_o}{T_j}) \, q_j \qquad (10.21)$$

Now we have

$$\dot{W}^{rev} = \dot{m} \sum (1 - \frac{T_o}{T_j}) \, q_j + \dot{m} \, (\psi_i - \psi_e)$$

divide by the mass flow rate to get

$$w^{rev} = \sum (1 - \frac{T_o}{T_j}) \, q_j + \psi_i - \psi_e$$

The last difference in exergies are from Eq.8.23

$$\psi_i - \psi_e = (h_{tot\ i} - T_o s_i) - (h_{tot\ e} - T_o s_e)$$

which when substituted gives Eq.8.14.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.11

What is the second law efficiency of a Carnot Heat engine?

The Carnot Heat engine is by definition reversible and thus it delivers the maximum amount of work possible. It has a second law eficiency of 100%.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.12

What is the second law efficiency of a reversible heat engine?

Since the reversible heat engine has no entropy generation it produces the maximum work possible and the actual work is the reversible work so it has a second law efficiency of 100%.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.13

For a nozzle what is the output and input (source) expressed in exergies?

For the nozzle a high pressure low velocity inlet flow generates a higher velocity in the exit flow at the expense of the pressure. The desired output is the higher velocity expressed as kinetic energy, which is part of exergy. The source is the inlet high pressure expressed in flow exergy.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.14

Is the exergy equation independent of the energy and entropy equations?

No. The exergy equation is derived from the other balance equations by defining the exergy from the state properties and the reference dead state.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.15

Use the exergy balance equation to find the efficiency of a steady state Carnot heat engine operating between two fixed temperature reservoirs?

The exergy balance equation, Eq.8.38, for this case looks like

$$0 = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H - \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L - \dot{W} + 0 + 0 - 0 - 0$$

Steady state (LHS = 0) and dV/dt = 0, no mass flow terms, Carnot cycle so reversible and the destruction is then zero. From the energy equation we have

$$0 = \dot{Q}_H - \dot{Q}_L - \dot{W}$$

which we can subtract from the exergy balance equation to get

$$0 = -\frac{T_o}{T_H} \dot{Q}_H + \frac{T_o}{T_L} \dot{Q}_L$$

Solve for one heat transfer in terms of the other

$$\dot{Q}_L = \frac{T_L}{T_H} \dot{Q}_H$$

The work from the energy equation is

$$\dot{W} = \dot{Q}_H - \dot{Q}_L = \dot{Q}_H \left[\, 1 - \frac{T_L}{T_H} \,\right]$$

from which we can read the Carnot cycle efficiency as we found in Chapter 7.

Exergy, Reversible work

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.16

A control mass gives out 10 kJ of energy in the form of

a. Electrical work from a battery
b. Mechanical work from a spring
c. Heat transfer at 500°C

Find the change in exergy of the control mass for each of the three cases.

Solution:

a) Work is exergy $\Delta\Phi = -W_{el} =$ **-10 kJ**

b) Work is exergy $\Delta\Phi = -W_{spring} =$ **-10 kJ**

c) Give the heat transfer to a Carnot heat engine and W is exergy

$$\Delta\Phi = -\left[1 - \frac{T_0}{T_H}\right] Q_{out} = -\left(1 - \frac{298.15}{773.15}\right) 10 = \mathbf{-6.14\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.17

A fraction of some power to a motor (1), 2 kW, is turned into heat transfer at 500 K (2) and then it dissipates in the ambient at 300 K (3). Give the rates of exergy along the process 1-2-3.

Solution:

The exergy of an amount of heat transfer equals the possible work that can be extracted. This is the work out of a Carnot heat engine with heat transfer to the ambient as the other reservoir. The result is from Chapter 5 as also shown in Eq. 8.1 and Eq. 8.38

1: $\dot{\Phi} = \dot{W} = \mathbf{2\ kW}$

2: $\dot{\Phi} = \dot{W}_{rev\ HE} = (1 - \frac{T_o}{T})\dot{Q} = (1 - \frac{300}{500})\ 2\ kW = \mathbf{0.8\ kW}$

3: $\dot{\Phi} = \dot{W}_{rev\ HE} = (1 - \frac{T_o}{T_o})\dot{Q} = (1 - \frac{300}{300})\ 2\ kW = \mathbf{0\ kW}$

As the energy transforms from wotrk to heat transfer it loses exergy and as the heat transfer goes to lower and lower T its exergy value drops ending as zero at the ambient T.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.18

A refrigerator should remove 1.5 kW from the cold space at -10^{o}C while it rejects heat to the kitchen at 25^{o}C. Find the reversible work.

The reversible work is related to the Carnot cycle work as the the two reservoirs are at constant temperatures.

$$\dot{W} = \dot{Q}_L / \beta \; ; \qquad \beta = \dot{Q}_L / \dot{W}_{carnot} = \frac{T_L}{T_H - T_L} = \frac{263.15}{25 - (-10)} = 7.52$$

In general we have defined the reversible work with the standard sign definition

$$\dot{W}^{rev} = - \dot{Q}_L / \beta = - \frac{1.5}{7.52} \text{ kW} = \mathbf{-0.2\ kW}$$

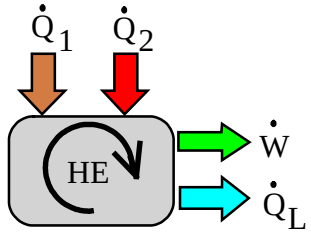
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.19

A heat engine receives 5 kW at 800 K and 10 kW at 1000 K rejecting energy by heat transfer at 600 K. Assume it is reversible and find the power output. How much power could be produced if it could reject energy at T_o = 298 K?

Solution:

C.V. The heat engine, this is in steady state.



Energy Eq.: $0 = \dot{Q}_1 + \dot{Q}_2 - \dot{Q}_L - \dot{W}$

Entropy Eq.: $0 = \dfrac{\dot{Q}_1}{T_1} + \dfrac{\dot{Q}_2}{T_2} - \dfrac{\dot{Q}_L}{T_L} + 0$

Now solve for $\dot{Q}_L$ from the entropy equation

$$\dot{Q}_L = \frac{T_L}{T_1}\dot{Q}_1 + \frac{T_L}{T_2}\dot{Q}_2 = \frac{600}{800} \times 5 + \frac{600}{1000} \times 10 = 9.75 \text{ kW}$$

Substitute into the energy equation and solve for the work term

$$\dot{W} = \dot{Q}_1 + \dot{Q}_2 - \dot{Q}_L = 5 + 10 - 9.75 = \mathbf{5.25\ kW}$$

For a low temperature of 298 K we can get

$$\dot{Q}_{L2} = \frac{298}{600}\dot{Q}_L = 4.843 \text{ kW}$$

$$\dot{W} = \dot{Q}_1 + \dot{Q}_2 - \dot{Q}_L = 5 + 10 - 4.843 = \mathbf{10.16\ kW}$$

Remark: Notice the large increase in the power output.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.20

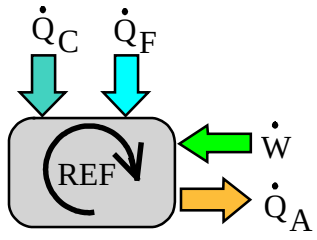
A household refrigerator has a freezer at T_F and a cold space at T_C from which energy is removed and rejected to the ambient at T_A as shown in Fig. P8.20.

Assume that the rate of heat transfer from the cold space, $\dot{Q}_C$, is the same as from the freezer, $\dot{Q}_F$, find an expression for the minimum power into the heat pump.

Evaluate this power when $T_A = 20°C$, $T_C = 5°C$, $T_F = -10°C$, and $\dot{Q}_F = 3$ kW.

Solution:

C.V. Refrigerator (heat pump), Steady, no external flows except heat transfer.



Energy Eq.: $\dot{Q}_F + \dot{Q}_c + \dot{W}_{in} = \dot{Q}_A$

(amount rejected to ambient)

Reversible gives maximum work (minimum work in) as from Eq. 8.1 or 8.11 on rate form (standard sign notation for work).

$$\dot{W}^{rev} = \dot{Q}_F \left[1 - \frac{T_A}{T_F}\right] + \dot{Q}_c \left[1 - \frac{T_A}{T_C}\right] - \dot{Q}_A \left[1 - \frac{T_A}{T_A}\right]$$

$$= 3\left[1 - \frac{293.15}{263.15}\right] + 3\left[1 - \frac{293.15}{278.15}\right] - 0$$

$$= \mathbf{-0.504\ kW} \qquad \text{(negative so work goes in)}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.21

An air compressor takes air in at the state of the surroundings 100 kPa, 300 K. The air exits at 400 kPa, 200°C using 100 kW of power. Determine the minimum compressor work input.

C.V. Compressor, Steady flow, minimum work in is reversible work.

Energy Eq.: $0 = h_1 - h_2 - w_c$ =>

$$-w_c = h_2 - h_1 = 475.8 - 300.47 = 175.33 \text{ kJ/kg}$$

$$\dot{m} = \dot{W}/-w_c = 100 \text{ kW}/175.33 = 0.57 \text{ kg/s}$$

$\psi_1 = 0$ at ambient conditions

Get the properties from the air table A.7.1 and correct standard entropy for the pressure

$$s_0 - s_2 = s^\circ_{T_0} - s^\circ_{T_2} - R \ln(P_0/P_2)$$

$$= 6.86926 - 7.3303 - 0.287 \ln(100/400) = -0.06317 \text{ kJ/kg K}$$

$$\psi_2 = h_2 - h_0 + T_0(s_0 - s_2) = 475.79 - 300.473 + 300\ (-0.06317)$$

$$= 156.365 \text{ kJ/kg}$$

$$-\dot{W}^{REV} = \dot{m}(\psi_2 - \psi_1) = 0.57 \text{ kg/s } (156.365 - 0) \text{ kJ/kg} = \mathbf{89.1\ kW} = \dot{W}_{c\ min}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

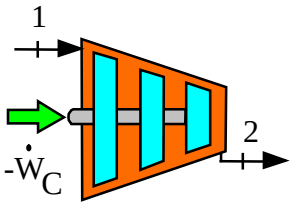
8.22

The compressor in a refrigerator takes refrigerant R-134a in at 100 kPa, –20°C and compresses it to 1 MPa, 60°C. With the room at 20°C find the minimum compressor work.

Solution:

C.V. Compressor out to ambient. Minimum work in is the reversible work.

Steady flow, 1 inlet and 2 exit



Energy Eq.: $w_c = h_1 - h_2 + q^{rev}$

Entropy Eq.: $s_2 = s_1 + \int dq/T + s_{gen} = s_1 + q^{rev}/T_o + 0$

$$\Rightarrow \quad q^{rev} = T_o(s_2 - s_1)$$

$$w_{c\,min} = h_1 - h_2 + T_o(s_2 - s_1)$$

$$= 387.22 - 441.89 + 293.15 \times (1.7818 - 1.7665)$$

$$= -54.67 + 4.4852$$

$$= \mathbf{-50.18\ kJ/kg}$$

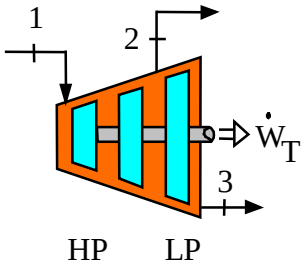
8.23

Calculate the reversible work out of the two-stage turbine shown in Problem 4.86, assuming the ambient is at 25°C. Compare this to the actual work which was found to be 18.08 MW.

C.V. Turbine. Steady flow, 1 inlet and 2 exits.

Use Eq. 8.11 for steady flow with q = 0 for adiabatic turbine.



Supply state 1: 20 kg/s at 10 MPa, 500°C

Process steam 2: 5 kg/s, 0.5 MPa, 155°C,

Exit state 3: 20 kPa, x = 0.9

Table B.1.3: $h_1 = 3373.7$, $h_2 = 2755.9$ kJ/kg,

$s_1 = 6.5966$, $s_2 = 6.8382$ kJ/kg K

Table B.1.2: $h_3 = 251.4 + 0.9 \times 2358.3 = 2373.9$ kJ/kg,

$s_3 = 0.8319 + 0.9 \times 7.0766 = 7.2009$ kJ/kg K

$$\dot{W}^{rev} = (\dot{m}_1 h_1 - \dot{m}_2 h_2 - \dot{m}_3 h_3) - T_0(\dot{m}_1 s_1 - \dot{m}_2 s_2 - \dot{m}_3 s_3)$$

$$= 20 \times 3373.7 - 5 \times 2755.9 - 15 \times 2373.9$$

$$- 298.15\,(20 \times 6.5966 - 5 \times 6.8382 - 15 \times 7.2009)$$

$$= \mathbf{21.14\ MW} = \dot{W}^{ac} + \dot{Q}^{rev} = 18084\ \text{kW} + 3062.7\ \text{kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.24

Find the specific reversible work for a steam turbine with inlet 4 MPa, 500°C and an actual exit state of 100 kPa, x = 1.0 with a 25°C ambient.

Solution:

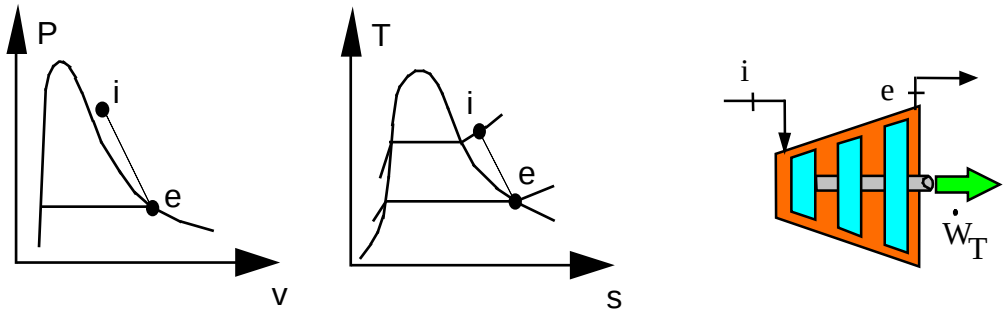
Steam turbine $T_o = 25°C = 298.15$ K

Inlet state: Table B.1.3 $h_i = 3445.2$ kJ/kg; $s_i = 7.090$ kJ/kg K

Exit state: Table B.1.2 $h_e = 2675.5$ kJ/kg; $s_e = 7.3593$ kJ/kg K

From Eq.8.14 asuming it to be adiabatic,

$$w^{rev} = (h_i - T_o s_i) - (h_e - T_o s_e) = (h_i - h_e) + T_o(s_e - s_i)$$
$$= (3445.2 - 2675.5) + 298.2(7.3593 - 7.0900)$$
$$= 769.7 + 80.3 = \mathbf{850.0\ kJ/kg}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.25

A steam turbine receives steam at 6 MPa, 800°C. It has a heat loss of 49.7 kJ/kg and an isentropic efficiency of 90%. For an exit pressure of 15 kPa and surroundings at 20°C, find the actual work and the reversible work between the inlet and the exit.

C.V. Reversible adiabatic turbine (isentropic)

$w_T = h_i - h_{e,s}$; $s_{e,s} = s_i = 7.6566$ kJ/kg K, $h_i = 4132.7$ kJ/kg

$x_{e,s} = (7.6566 - 0.7548)/7.2536 = 0.9515,$

$h_{e,s} = 225.91 + 0.9515 \times 2373.14 = 2483.9$ kJ/kg

$w_{T,s} = 4132.7 - 2483.9 = 1648.79$ kJ/kg

C.V. Actual turbine

$w_{T,ac} = \eta w_{T,s} =$ **1483.91 kJ/kg**

$= h_i - h_{e,ac} - q_{loss} \Rightarrow$

$h_{e,ac} = h_i - q_{loss} - w_{T,ac} = 4132.7 - 49.7 - 1483.91 = 2599.1$ kJ/kg

Actual exit state: P, h $\Rightarrow$ saturated vapor, $s_{e,ac} = 8.0085$ kJ/kg K

C.V. Reversible process, work from Eq.8.14

$$q^R = T_0(s_{e,ac} - s_i) = 293.15 \times (8.0085 - 7.6566) = 103.16 \frac{\text{kJ}}{\text{kg}}$$

$w^R = h_i - h_{e,ac} + q^R = 4132.7 - 2599.1 + 103.16 =$ **1636.8 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.26

A compressor in a refrigerator receives R-410A at 150 kPa, -40°C and it brings it up to 600 kPa, using an actual specific work of 58.65 kJ/kg in an adiabatic compression. Find the specific reversible work.

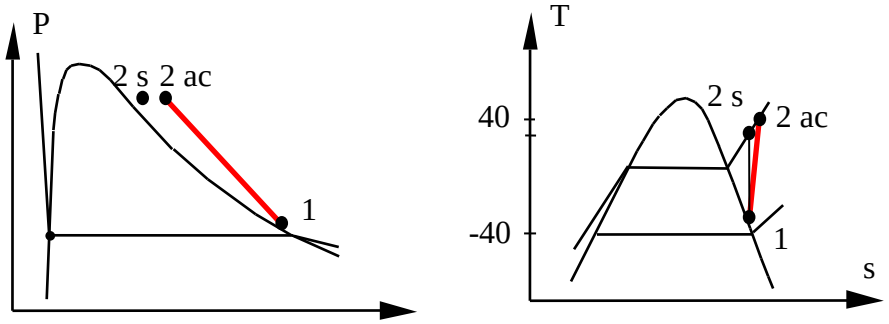
Energy Eq.: $0 = h_1 - h_2 - w$

State 1: B.4.2 $h_1 = 263.99$ kJ/kg, $s_1 = 1.1489$ kJ/kg K

$h_2 = h_1 - w = 263.99 + 58.65 = 322.64$ kJ/kg

State 2: B.4.2 P, h_2 => $s_2 = 1.2152$ kJ/kg K

$$w^{rev} = \psi_1 - \psi_2 = h_1 - h_2 - T_0 (s_1 - s_2)$$
$$= -58.65 - 298.15 (1.1489 - 1.2152)$$
$$= -58.65 + 19.767 = \mathbf{-38.9\ kJ/kg}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.27

Air flows through a constant pressure heating device, shown in Fig. P8.27. It is heated up in a reversible process with a work input of 200 kJ/kg air flowing. The device exchanges heat with the ambient at 300 K. The air enters at 300 K, 400 kPa. Assuming constant specific heat develop an expression for the exit temperature and solve for it by iterations.

C.V. Total out to T_0

Energy Eq.: $h_1 + q_0^{rev} - w^{rev} = h_2$

Entropy Eq.: $s_1 + q_0^{rev}/T_0 = s_2 \quad \Rightarrow \quad q_0^{rev} = T_0(s_2 - s_1)$

$h_2 - h_1 = T_0(s_2 - s_1) - w^{rev}$ (same as from Eq. 8.14)

Constant C_p gives: $C_p(T_2 - T_1) = T_0 C_p \ln (T_2/T_1) + 200$

The energy equation becomes

$$\mathbf{T_2 - T_0 \ln(\frac{T_2}{T_1}) = T_1 + \frac{200}{C_p}}$$

$T_1 = 300$ K, $C_p = 1.004$ kJ/kg K, $T_0 = 300$ K

$$T_2 - 300 \ln (\frac{T_2}{300}) = 300 + \frac{200}{1.004} = 499.3 \text{ K}$$

Now trial and error on T_2

At 600 K LHS = 392 (too low)

At 800 K LHS = 505.75

Linear interpolation gives $\mathbf{T_2 = 790 K}$ (LHS = 499.5 **OK**)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.28

An adiabatic and reversible air compressor takes air in at 100 kPa, 310 K. The air exits at 600 kPa at the rate of 0.4 kg/s. Determine the minimum compressor work input and repeat for an inlet at 295 K instead. Why is the work less for a lower inlet *T*?

Compressor. Reversible adiabatic, constant s:

Inlet at 310 K: $$T_{2S} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 310\left(\frac{600}{100}\right)^{0.2857} = 517.2 \text{ K}$$

The reversible process ensures the minimum work input.

$$\dot{W} = \dot{m}(-w_S) = \dot{m}C_{P0}(T_{2S} - T_1)$$
$$= 0.4 \text{ kg/s} \times 1.004 \text{ kJ/kg-K} \times (517.2 - 310) \text{ K}$$
$$= \mathbf{83.2 \text{ kW}}$$

Inlet at 295 K: $$T_{2S} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 295\left(\frac{600}{100}\right)^{0.2857} = 492.2 \text{ K}$$

$$\dot{W} = \dot{m}(-w_S) = \dot{m}C_{P0}(T_{2S} - T_1) = 0.4 \times 1.004\ (492.2 - 295)$$
$$= 0.4 \text{ kg/s} \times 1.004 \text{ kJ/kg-K} \times (492.2 - 295) \text{ K}$$
$$= \mathbf{79.2 \text{ kW}}$$

The work term is reduced due to the reduced specific volume, v_1, recall Eq. 7.15 for the indicated shaft work.

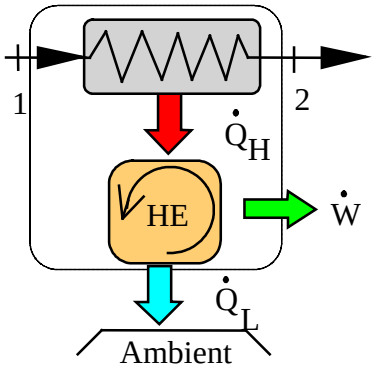
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.29

An air flow of 5 kg/min at 1500 K, 125 kPa goes through a constant pressure heat exchanger, giving energy to a heat engine shown in Figure P8.29. The air exits at 500 K and the ambient is at 298 K, 100 kPa. Find the rate of heat transfer delivered to the engine and the power the engine can produce.

Solution:

C.V. Heat exchanger



Continuity eq.: $\dot{m}_1 = \dot{m}_2$;

Energy Eq.4.12: $\dot{m}_1 h_1 = \dot{m}_1 h_2 + \dot{Q}_H$

Table A.7.1: $h_1 = 1635.8$ kJ/kg,

$h_2 = 503.36$ kJ/kg, $s_1 = 8.61209$ kJ/kg K

$s_2 = 7.38692$ kJ/kg K

$$\dot{Q}_H = \dot{m}(h_1 - h_2) = \frac{5}{60}\frac{\text{kg}}{\text{s}}(1635.8 - 503.36)\frac{\text{kJ}}{\text{kg}} = \mathbf{94.37\ kW}$$

Notice T_H is not constant so we do not know the heat engine efficiency.

C.V. Total system for which we will write the second law.

Entropy Equation 7.8: $\dot{m}\, s_1 + \dot{S}_{gen} = \dot{m}\, s_2 + \dot{Q}_L/T_o$

Process: Assume reversible $\dot{S}_{gen} = 0$, and P = C for air

$$\dot{Q}_L = T_o\, \dot{m}\, (s_1 - s_2) = 298\ \text{K}\ \frac{5}{60}\frac{\text{kg}}{\text{s}}(8.61209 - 7.38692)\frac{\text{kJ}}{\text{kg K}}$$

$$= 30.425\ \text{kW}$$

Energy equation for the heat engine gives the work as

$$\dot{W} = \dot{Q}_H - \dot{Q}_L = 94.37 - 30.425 = \mathbf{63.9\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.30

Water at 800^{o}C, 15 MPa is flowing through a heat exchanger giving off energy to come out as saturated liquid water at 15 MPa in a steady flow process. Find the specific heat transfer and the specific flow-exergy the water has delivered.

Let us fix the states first from Table B.1.2 and B.1.3:

State 1 (in): h = 4092.43 kJ/kg, s = 7.2040 kJ/kg K

State 2 (ex): h = 1610.45 kJ/kg, s = 3.6847, T = 342.24^{o}C = 615.4 K

CV Heat exchanger, no work.

Energy Eq.: $q_{out} = h_{in} - h_{ex} = 4092.43 - 1610.45 =$ **2482 kJ/kg**

Flow exergy: $\Delta\psi = \psi_{in} - \psi_{ex} = (h - T_o s)_{in} - (h - T_o s)_{ex}$

$= q_{out} - T_o(s_{in} - s_{ex})$

$= 2482 - 298.15(7.2040 - 3.6847)$

$=$ **1432.7 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.31

A rock bed consists of 6000 kg granite and is at 70°C. A small house with lumped mass of 12000 kg wood and 1000 kg iron is at 15°C. They are now brought to a uniform final temperature with no external heat transfer by connecting the house and rock bed through some heat engines. If the process is reversible, find the final temperature and the work done in the process.

Solution:

Take C.V. Total (rockbed and heat engine)

Energy Eq.: $m_{rock}(u_2 - u_1) + m_{wood}(u_2 - u_1) + m_{Fe}(u_2 - u_1) = -{}_1W_2$

Entropy Eq.: $m_{rock}(s_2 - s_1) + m_{wood}(s_2 - s_1) + m_{Fe}(s_2 - s_1) = \emptyset$

$$(mC)_{rock} \ln \frac{T_2}{T_1} + (mC)_{wood} \ln \frac{T_2}{T_1} + (mC)_{Fe} \ln \frac{T_2}{T_1} = \emptyset$$

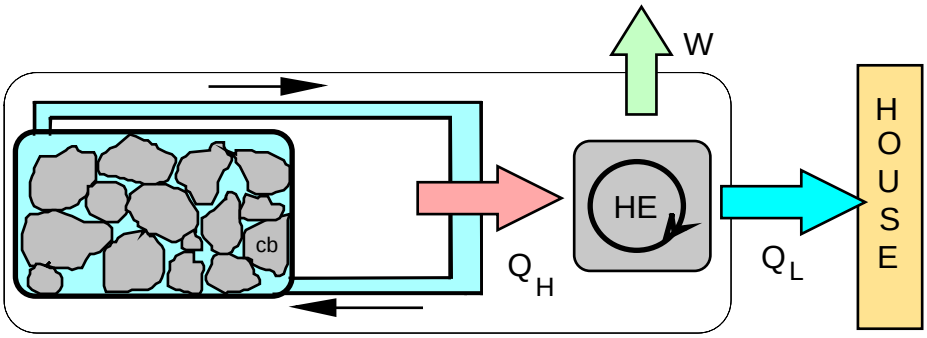
$$6000 \times 0.89 \ln (T_2/343.15) + 12000 \times 1.26 \ln (T_2/288.15)$$
$$+ 1000 \times 0.46 \ln (T_2/288.15) = \emptyset$$

$$\Rightarrow \quad \mathbf{T_2 = 301.3\ K}$$

Now from the energy equation

$$-{}_1W_2 = 6000\ \text{kg} \times 0.89\ \text{kJ/kgK} \times (301.3 - 343.15)\ \text{K}$$
$$+ (12000 \times 1.26 + 1000 \times 0.46)\ \text{kJ/K} \times (301.3 - 288.15)\ \text{K}$$

$$\Rightarrow {}_1W_2 = \mathbf{18\ 602\ kJ}$$



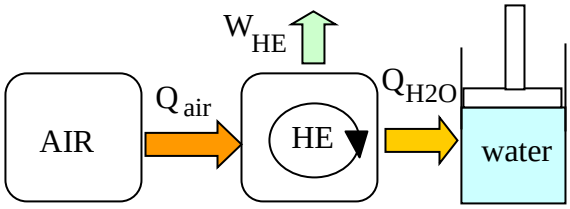
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.32

A constant pressure piston/cylinder has 1 kg of saturated liquid water at 100 kPa. A rigid tank contains air at 1200 K, 1000 kPa. They are now thermally connected by a reversible heat engine cooling the air tank and boiling the water to saturated vapor. Find the required amount of air and the work out of the heat engine.

CV. Tank, piston/cyl. and the heat engine.

The minimum amount of air is when T_2 of air equals water T = 99.62 C.



State: 1 = initial air
2 = final air
3 = initial water
4 = final water

For this CV only W_{HE} and W_{pist} cross the control surface no heat transfer. The entropy equation Eq.6.3 and Eq.6.37 for a reversible process becomes

$$(S_2 - S_1)_{tot} = m_{air}(s_2 - s_1) + m_{H2O}(s_4 - s_3) = 0 + 0$$

$$m_{H2O}(s_4 - s_3) = m_{H2O}\, s_{fg} = 1 \text{ kg} \times 6.0568 \text{ kJ/kg-K} = 6.0568 \text{ kJ/K}$$

$$s_2 - s_1 = C_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} = C_v \ln \frac{T_2}{T_1} = 0.717 \ln \frac{372.77}{1200}$$

$$= -0.838256 \text{ kJ/kg-K}$$

Now solve for the air mass from entropy equation

$$m_{air} = -m_{H2O}(s_4 - s_3) / (s_2 - s_1) = -\frac{6.0568}{-0.838256} = \mathbf{7.2255 \text{ kg}}$$

Let us find the two heat transfers

Energy Eq, water: $m_{H2O}(u_4 - u_3) = Q_{H2O} - W_{H2O}$; $W_{H2O} = Pm(v_4 - v_3)$

$$Q_{H2O} = m_{H2O}(u_4 - u_3) + W_{H2O} = m_{H2O}(h_4 - h_3) = m_{H2O}\, h_{fg} = 2258.02 \text{ kJ}$$

Energy Eq. air: $m_{air}(u_2 - u_1) = -Q_{air} - 0 = m_{air}\, C_v\, (T_2 - T_1)$

$$Q_{air} = 7.2255 \text{ kg } 0.717\ (1200 - 372.77) = 4285.6 \text{ kJ}$$

Now the work out of the heat engine is

$$W_{HE} = Q_{air} - Q_{H2O} = 4285.6 - 2258.02 = \mathbf{2027.6 \text{ kJ}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.33

A piston/cylinder has forces on the piston so it keeps constant pressure. It contains 2 kg of ammonia at 1 MPa, 40°C and is now heated to 100°C by a reversible heat engine that receives heat from a 200°C source. Find the work out of the heat engine.

C.V. Ammonia plus heat engine

Energy: $m_{am}(u_2 - u_1) = {}_1Q_{2,200} - W_{H.E.} - {}_1W_{2,pist}$

Entropy: $m_{am}(s_2 - s_1) = {}_1Q_2/T_{res} + 0$

$\Rightarrow \quad {}_1Q_2 = m_{am}(s_2 - s_1)T_{res}$

Process: P = const. $\Rightarrow {}_1W_2 = P(v_2 - v_1)m_{am}$

Substitute the piston work term and heat transfer into the energy equation

$W_{H.E.} = m_{am}(s_2 - s_1)T_{res} - m_{am}(h_2 - h_1)$

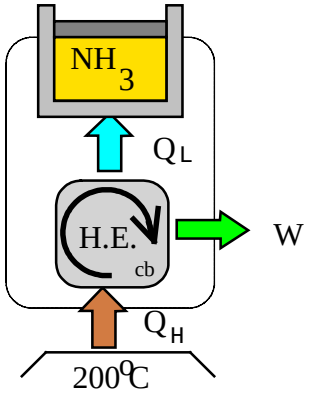


Table B.2.2: $h_1 = 1508.5$ kJ/kg, $s_1 = 5.1778$ kJ/kg K,

$h_2 = 1664.3$ kJ/kg, $s_2 = 5.6342$ kJ/kg K

$$W_{H.E.} = 2 \times [(5.6342 - 5.1778)473.15 - (1664.3 - 1508.5)] = \mathbf{120.3\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.34

A basement is flooded with 16 m^3 of water at 15^{o}C. It is pumped out with a small pump driven by a 0.75 kW electric motor. The hose can reach 8 m vertically up and to ensure the water can flow over the edge of a dike it should have a velocity of 20 m/s at that point generated by a nozzle, see Fig. P8.34. Find the maximum flow rate you can get and how fast the basement can be emptied.

C.V. Pump plus hose and nozzle, single steady state flow. For maximum flow rate assume reversible process so from Eq.8.14:

$$w^{rev} = T_o\,(s_2 - s_1) - (h_{2\,tot} - h_{1\,tot}) + 0$$

Since we have no heat transfer and reversible s is constant and with a liquid flow T is also constant so $h_2 = h_1$. We could also have used Bernoulli equation.

$$w^{rev} = -\left(\frac{1}{2}V_2^2 + gH - 0\right) = -\left(\frac{1}{2}\,20^2 + 9.81 \times 8\right) = -278.5 \text{ J/kg}$$

$$\dot{m} = \dot{W}/\,(-w^{rev}) = \frac{0.75 \text{ kW}}{0.2785 \text{ kJ/kg}} = \mathbf{2.693\ kg/s}$$

$$m = V/v = 16\ m^3 / 0.001\ m^3/kg = 16\,000 \text{ kg}$$

$$\Delta t = m / \dot{m} = \frac{16\,000 \text{ kg}}{2.693 \text{ kg/s}} = 5941 \text{ sec} = \mathbf{99\ min.}$$

Irreversibility

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.35

A 20^{o}C room is heated with a 2000 W electric baseboard heater. What is the rate of irreversibility?

Let us not consider any storage in the room or any heat loss but just the effect of the heating process. Electric power comes in to the heater and leaves as heat transfer to the room air.

C.V. heater

Entropy Eq.: $0 = -\dfrac{\dot{Q}}{T_{air}} + \dot{S}_{gen} \quad \Rightarrow \quad \dot{S}_{gen} = \dfrac{\dot{Q}}{T_{air}}$

Irreversibility: $\dot{I} = T_o \, \dot{S}_{gen} = 293.15 \text{ K} \times \dfrac{2000 \text{ W}}{293.15 \text{ K}} = \mathbf{2000 \text{ W}}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.36

A refrigerator removes 1.5 kW from the cold space at -10^{o}C using 750 W of power input while it rejects heat to the kitchen at 25^{o}C. Find the rate of irreversibility.

C.V. Refrigerator

Energy Eq.: $0 = \dot{Q}_L + \dot{W} - \dot{Q}_H \quad \Rightarrow \quad \dot{Q}_H = \dot{Q}_L + \dot{W}$

Entropy Eq.: $0 = \dfrac{\dot{Q}_L}{T_L} - \dfrac{\dot{Q}_H}{T_H} + \dot{S}_{gen} \quad \Rightarrow \quad \dot{S}_{gen} = \dfrac{\dot{Q}_H}{T_H} - \dfrac{\dot{Q}_L}{T_L}$

$$\dot{Q}_H = \dot{Q}_L + \dot{W} = 1.5 \text{ kW} + 0.75 \text{ kW} = 2.25 \text{ kW}$$

$$\dot{S}_{gen} = \frac{2250 \text{ W}}{298.15 \text{ K}} - \frac{1500 \text{ W}}{263.15 \text{ K}} = 1.8464 \text{ W/K}$$

Irreversibility: $\dot{I} = T_o \dot{S}_{gen} = 298.15 \text{ K} \times 1.8464 \text{ W/K} = \mathbf{550\ W}$

8.37

Calculate the irreversibility for the condenser in Problem 7.100 assuming an ambient temperature at 17°C.

Solution:

C.V. Condenser. Steady state with no shaft work term.

Energy Equation 4.12: $\dot{m}\, h_i + \dot{Q} = \dot{m} h_e$

Entropy Equation 7.8: $\dot{m}\, s_i + \dot{Q}/T + \dot{S}_{gen} = \dot{m}\, s_e$

Properties are from Table B.1.2

$h_i = 225.91 + 0.9 \times 2373.14 = 2361.74$ kJ/kg , $\quad h_e = 225.91$ kJ/kg

$s_i = 0.7548 + 0.9 \times 7.2536 = 7.283$ kJ/kg K, $\quad s_e = 0.7548$ kJ/kg K

From the energy equation

$$\dot{Q}_{out} = -\dot{Q} = \dot{m}\,(h_i - h_e) = 5(2361.74 - 225.91) = 10679 \text{ kW}$$

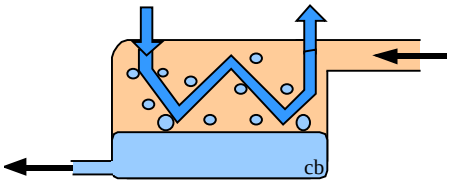
From the entropy equation

$$\dot{S}_{gen} = \dot{m}\,(s_e - s_i) + \dot{Q}_{out}/T = 5(0.7548 - 7.283) + 10679/(273.15 + 17)$$

$$= -32.641 + 36.805 = 4.164 \text{ kW/K}$$

From Eq.8.13,

$$\dot{I} = T_o\, \dot{S}_{gen} = 290.15 \times 4.164 = \mathbf{1208\ kW}$$



Often the cooling media flows inside a long pipe carrying the energy away.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.38

A throttle process is an irreversible process. Assume an air flow at 1000 kPa, 400 K runs through a valve out to ambient 100 kPa. Find the reversible work and irreversibility assuming an ambient temperature at 25°C.

Solution:

C.V. Throttle. Steady state, adiabatic q = 0 and no shaft work w = 0.

Energy Eq.4.13: $h_e = h_i$ so temperature is constant

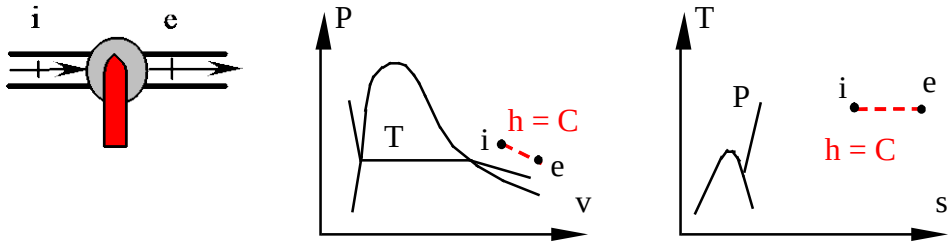
$$s_e - s_i = s^o_{Te} - s^o_{Ti} - R \ln(P_e/P_i) = -0.287 \ln \frac{1000}{100} = -0.6608 \text{ kJ/kg K}$$

The reversible work is the difference in exergy expressed in Eq.6.11, 8.14 and 8.29 per unit mass flow

$$w^{rev} = \psi_i - \psi_e = (h_i - T_o s_i) - (h_e - T_o s_e) = (h_i - h_e) + T_o(s_e - s_i)$$

$$= 0 + 298.15 (- 0.6608) = \mathbf{197 \text{ kJ/kg}}$$

$$i = w^{rev} - w = 197 - 0 = \mathbf{197 \text{ kJ/kg}}$$



Process is in the ideal gas region

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.39

A compressor in a refrigerator receives R-410A at 150 kPa, -40°C and it brings it up to 600 kPa, 40°C in an adiabatic compression. Find the specific work, reversible work, entropy generation and irreversibility.

States: 1: B.4.2 $h_1 = 263.99$ kJ/kg, $s_1 = 1.1489$ kJ/kg K

2: B.4.2 $h_2 = 322.64$ kJ/kg, $s_2 = 1.2152$ kJ/kg K

C.V. Compressor, steady state, q = 0, no KE, PE energies.

Energy Eq.: $w = h_1 - h_2 = 263.99 - 322.64 =$ **–58.65 kJ/kg**

Entropy Eq.: $0 = s_1 - s_2 + s_{gen}$ ⇨

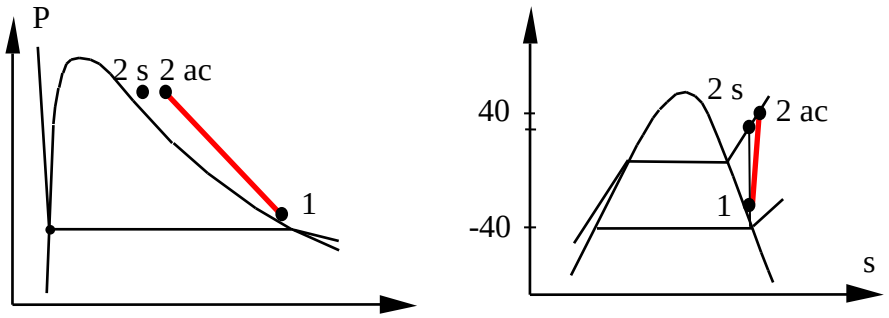
$s_{gen} = s_2 - s_1 = 1.2152 - 1.1489 =$ **0.0663 kJ/kg-K**

$w^{rev} = \psi_1 - \psi_2 = h_1 - h_2 - T_0 (s_1 - s_2)$

$= -58.65 - 298.15 (1.1489 - 1.2152)$

$= -58.65 + 19.767 =$ **–38.9 kJ/kg**

Irreversibility: $i = T_o s_{gen} = 298.15 \text{ K} \times 0.0663 \text{ kJ/kg-K} =$ **19.77 kJ/kg**

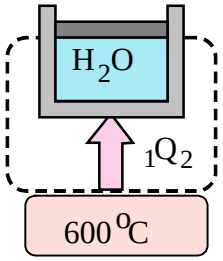


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.40

A constant pressure piston/cylinder contains 2 kg of water at 5 MPa and 100°C. Heat is added from a reservoir at 600°C to the water until it reaches 600°C. We want to find the total irreversibility in the process.

Solution:
C.V. Piston cylinder out to the reservoir (incl. the walls).



Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Entropy Eq.: $m(s_2 - s_1) = {}_1Q_2/T_{res} + {}_1S_{2\,gen}$

State 1: $h_1 = 422.71$ kJ/kg, $s_1 = 1.303$ kJ/kg K

State 2: $h_2 = 3666.47$ kJ/kg, $s_2 = 7.2588$ kJ/kg K

Process: $P = C \Rightarrow {}_1W_2 = P(V_2 - V_1)$

From the energy equation we get

$${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = m(h_2 - h_1) = 2(3666.47 - 422.71) = 6487.5 \text{ kJ}$$

From the entropy equation we get

$${}_1S_{2\,gen} = m(s_2 - s_1) - \frac{{}_1Q_2}{T_{res}} = 2(7.2588 - 1.303) - \frac{6487.5}{273 + 600} = 4.4816 \frac{\text{kJ}}{\text{K}}$$

Now the irreversibility is from Eq. 8.18

$${}_1I_2 = m\,{}_1i_2 = T_o\ {}_1S_{2\,gen} = 298.15 \text{ K} \times 4.4816 \frac{\text{kJ}}{\text{K}} = \mathbf{1336\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.41

A constant "flow" of steel parts 2 kg/s at 20°C goes into a furnace where they are heat treated to 900°C by a source at an average 1250 K. Find the reversible work and the irreversibility in this process?

Energy Eq.: $0 = \dot{m}(h_i - h_e) + \dot{Q}$

Entropy Eq.: $0 = \dot{m}(s_i - s_e) + \dot{Q} / T_s + \dot{S}_{gen}$

$$\dot{Q} = \dot{m}(h_e - h_i) = \dot{m}C_P (T_e - T_i) = 2 \text{ kg/s} \times 0.46 \text{ kJ/kg-K} \times 880 \text{ K}$$
$$= 809.6 \text{ kW}$$

$$\dot{S}_{gen} = \dot{m}(s_e - s_i) - \dot{Q} / T_s = \dot{m}C_P \ln(T_e/T_i) - \dot{Q} / T_s$$
$$= 2 \text{ kg/s} \times 0.46 \text{ kJ/kg-K} \times \ln(1173 / 293) - 809.6 \text{ kW} / 1250 \text{ K}$$
$$= 0.6285 \text{ kW/K}$$

$$\dot{I} = T_0 \dot{S}_{gen} = 293 \text{ K} \times 0.6285 \text{ kW/K} = \mathbf{184.15 \text{ kW}}$$

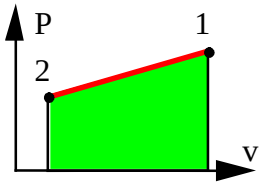
The reversible work is equal to the irreversibility plus the actual work, Eq.8.12

$$\dot{W}^{rev} = \dot{I} + \dot{W}_{ac} = \dot{I} = \mathbf{184.15 \text{ kW}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.42

Calculate the reversible work and irreversibility for the process described in Problem 3.146, assuming that the heat transfer is with the surroundings at 20°C.
Solution:



Linear spring gives

$$ {}_1W_2 = \int PdV = \tfrac{1}{2}(P_1 + P_2)(V_2 - V_1) $$

$$ {}_1Q_2 = m(u_2 - u_1) + {}_1W_2 $$

Equation of state: PV = mRT

State 1: $V_1 = mRT_1/P_1 = 2 \times 0.1889 \times 673.15 /500 = 0.5087\ m^3$

State 2: $V_2 = mRT_2/P_2 = 2 \times 0.1889 \times 313.15 /300 = 0.3944\ m^3$

$${}_1W_2 = \tfrac{1}{2}(500 + 300)(0.3944 - 0.5087) = -45.72\ kJ$$

From Figure 3.26: $C_p(T_{avg}) = 5.25\ R = 0.99 \Rightarrow C_V = 0.803 = C_p - R$

For comparison the value from Table A.5 at 300 K is $C_V = 0.653$ kJ/kg K

$${}_1Q_2 = mC_V(T_2 - T_1) + {}_1W_2 = 2 \times 0.803(40 - 400) - 45.72 = -623.9\ kJ$$

$$ {}_1W_2^{rev} = T_o(S_2 - S_1) - (U_2 - U_1) + {}_1Q_2\,(1 - T_o/T_H) $$

$$ = T_o m(s_2 - s_1) + {}_1W_2^{ac} - {}_1Q_2\ T_o/T_o $$

$$ = T_o m[C_P \ln(T_2 / T_1) - R \ln(P_2 / P_1)] + {}_1W_2^{ac} - {}_1Q_2 $$

$$ = 293.15 \times 2\ [\ 0.99 \ln(313/673) - 0.1889 \ln(300/500)] - 45.72 + 623.9 $$

$$ = -387.8 - 45.72 + 623.9 = \mathbf{190.4\ kJ} $$

$$ {}_1I_2 = {}_1W_2^{rev} - {}_1W_2^{ac} = 190.4 - (-45.72) = \mathbf{236.1\ kJ} $$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.43

An air compressor receives atmospheric air at T_0 = 17°C, 100 kPa, and compresses it up to 1400 kPa. The compressor has an isentropic efficiency of 88% and it loses energy by heat transfer to the atmosphere as 10% of the isentropic work. Find the actual exit temperature and the reversible work.

C.V. Compressor

Isentropic: $w_{c,in,s} = h_{e,s} - h_i$; $s_{e,s} = s_i$

From table A.7.1 and entropy equation we get

$$s^o_{Te\,s} = s^o_{Ti} + R \ln (P_e/P_i) = 6.83521 + 0.287 \ln(14) = 7.59262 \text{ kJ/kgK}$$

Back interpolate in Table A.7: $\Rightarrow h_{e,s} = 617.23$ kJ/kg

$$w_{c,in,s} = 617.23 - 290.43 = 326.8 \text{ kJ/kg}$$

Actual: $w_{c,in,ac} = w_{c,in,s}/\eta_c = 371.36$ kJ/kg; $q_{loss} = 32.68$ kJ/kg

$$w_{c,in,ac} + h_i = h_{e,ac} + q_{loss}$$

$$\Rightarrow h_{e,ac} = 290.43 + 371.36 - 32.68 = 629.1 \text{ kJ/kg}$$

$$\Rightarrow T_{e,ac} = \mathbf{621\ K}$$

Reversible: $w^{rev} = h_i - h_{e,ac} + T_0(s_{e,ac} - s_i)$

$$= 290.43 - 629.1 + 290.15 \times (7.6120 - 6.8357)$$

$$= -338.67 + 225.38 = \mathbf{-113.3\ kJ/kg}$$

Since q_{loss} is also to the atmosphere it is the net q exchanged with the ambient that explains the change in s.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.44

Two flows of air both at 200 kPa of equal flow rates mix in an insulated mixing chamber. One flow is 1 kg/s at 1500 K and the other is 2 kg/s at 300 K. Find the irreversibility in the process per kilogram of air flowing out.

C.V. Mixing chamber

Continuity Eq..: $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$

Energy Eq.: $\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$

Entropy Eq.: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen} = \dot{m}_3 s_3$

Properties from Table A.7

$h_3 = (h_1 + 2h_2)/3 = (1635.8 + 2 \times 300.47)/3 = 745.58$ kJ/kg

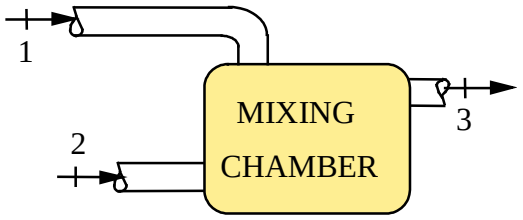
$\Rightarrow s^{\circ}_{T3} = 7.7848$ kJ/kg K (linear interpolation)

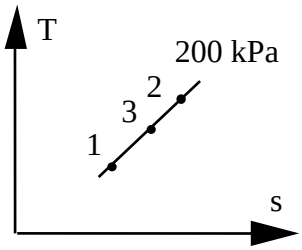
From the entropy equation (same P so no correction for that)

$\dot{S}_{gen}/\dot{m}_3 = s_3 - (s_1 + 2s_2)/3 = 7.7848 - (8.61208 + 2 \times 6.86926)/3$

$= 0.3346$ kJ/kg K

$i = \dot{I}/\dot{m}_3 = T_0 \dot{S}_{gen}/\dot{m}_3 = 298.15 \times 0.3346 =$ **99.76 kJ/kg**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.45

Fresh water can be produced from saltwater by evaporation and subsequent condensation. An example is shown in Fig. P8.45, where 150-kg/s saltwater, state 1, comes from the condenser in a large power plant. The water is throttled to the saturated pressure in the flash evaporator and the vapor, state 2, is then condensed by cooling with sea water. As the evaporation takes place below atmospheric pressure, pumps must bring the liquid water flows back up to P_0. Assume that the saltwater has the same properties as pure water, the ambient is at 20°C and that there are no external heat transfers. With the states as shown in the table below find the irreversibility in the throttling valve and in the condenser.

State	1	2	5	7	8
T [°C]	30	25	23	17	20
h [kJ/kg]	125.77	2547.2	96.5	71.37	83.96
s [kJ/kg K]	0.4369	8.558	0.3392	0.2535	0.2966

C.V. Valve. $P_2 = P_{sat}(T_2 = T_3) = 3.169$ kPa

Continuity Eq.: $\dot{m}_1 = m_{ex} = \dot{m}_2 + \dot{m}_3$

Energy Eq.: $h_1 = h_e$; Entropy Eq.: $s_1 + s_{gen} = s_e$

$h_e = h_1 \Rightarrow x_e = (125.77 - 104.87)/2442.3 = 0.008558$

$\Rightarrow s_e = 0.3673 + 0.008558 \times 8.1905 = 0.4374$ kJ/kg K

$\dot{m}_2 = (1 - x_e)\dot{m}_1 = 148.716$ kg/s

$s_{gen} = s_e - s_1 = 0.4374 - 0.4369 = 0.000494$ kJ/kg K

$\dot{I} = \dot{m}T_0 s_{gen} = 150 \times 293.15 \times 0.000494 =$ **21.72 kW**

C.V. Condenser.

Energy Eq.: $\dot{m}_2 h_2 + \dot{m}_7 h_7 = \dot{m}_2 h_5 + \dot{m}_7 h_8 \Rightarrow$

$$\dot{m}_7 = \dot{m}_2 \times (h_2 - h_5)/(h_8 - h_7) = 148.716 \times \frac{2547.2 - 96.5}{83.96 - 71.37} = 28\,948 \frac{\text{kg}}{\text{s}}$$

Entropy Eq.: $\dot{m}_2 s_2 + \dot{m}_7 s_7 + \dot{S}_{gen} = \dot{m}_2 s_5 + \dot{m}_7 s_8$

$\dot{I} = T_0 \dot{S}_{gen} = T_0 \left[\dot{m}_2(s_5 - s_2) + \dot{m}_7(s_8 - s_7) \right]$

$= 293.15[148.716(0.3392 - 8.558) + 28948(0.2966 - 0.2535)]$

$= 293.15 \times 25.392 =$ **7444 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.46

A rock bed consists of 6000 kg granite and is at 70°C. A small house with lumped mass of 12000 kg wood and 1000 kg iron is at 15°C. They are now brought to a uniform final temperature by circulating water between the rock bed and the house. Find the final temperature and the irreversibility of the process, assuming an ambient at 15°C.

C.V. Total Rockbed and house. No work, no Q irreversible process.

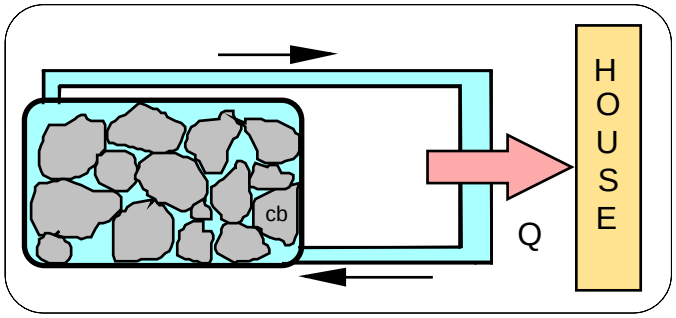
Energy Eq.: $(mC)_{rock}(T_2 - 70) + (mC_{wood} + mC_{Fe})(T_2 - 15) = \emptyset$

T_2 = **29.0°C = 302.2 K**

Entropy Eq.: $S_2 - S_1 = \sum m_i(s_2 - s_1)_i = 0 + S_{gen}$

$$S_{gen} = \sum m_i(s_2 - s_1)_i = 5340 \ln \frac{302.2}{343.15} + 15580 \ln \frac{302.2}{288.15} = 63.13 \text{ kJ/K}$$

$${}_1I_2 = (T_0)_1 S_{2,gen} = 288.15 \times 63.13 = \textbf{18 191 kJ}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.47

A computer CPU chip consists of 50 g silicon, 20 g copper, and 50g polyvinyl chloride (plastic). It now heats from ambient 25^{o}C to 70^{o}C in an adiabatic process as the computer is turned on. Find the amount of irreversibility.

C.V. CPU chip. The process has electrical work input and no heat transfer.

Entropy Eq.: $S_2 - S_1 = \sum m_i(s_2 - s_1)_i = \int dQ/T + {}_1S_{2\,gen} = {}_1S_{2\,gen}$

Irreversibility: ${}_1I_2 = T_0 \ {}_1S_{2\,gen}$

For the solid masses we will use the specific heats, Table A.3, and they all have the same temperature so

$$\sum m_i(s_2 - s_1)_i = \sum m_i C_i \ln(T_2 / T_1)_i = \ln (T_2/T_1) \sum m_i C_i$$

$$\sum m_i C_i = 0.05 \times 0.7 + 0.02 \times 0.42 + 0.05 \times 0.96 = 0.0914 \text{ kJ/K}$$

$${}_1S_{2\,gen} = S_2 - S_1 = 0.0914 \times \ln (343.15 / 288.15) = 0.016 \text{ kJ/K}$$

$${}_1I_2 = T_0 \ {}_1S_{2\,gen} = 298.15 \text{ K} \times 0.016 \text{ kJ/K} = \mathbf{4.77\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.48

A car air-conditioning unit has a 0.5-kg aluminum storage cylinder that is sealed with a valve and it contains 2 L of refrigerant R-134a at 500 kPa and both are at room temperature 20°C. It is now installed in a car sitting outside where the whole system cools down to ambient temperature at –10°C. What is the irreversibility of this process?

C.V. Aluminum and R-134a

Energy Eq.: $m_{Al}(u_2 - u_1)_{Al} + m_R(u_2 - u_1)_R = {}_1Q_2 - {}_1W_2 \quad ({}_1W_2 = 0)$

Entropy Eq.: $m_{AL}(s_2 - s_1)_{Al} + m_R(s_2 - s_1)_R = {}_1Q_2/T_0 + {}_1S_{2\,gen}$

Table A.3 for specific heat $C_{v,Al} = C_{p,Al} = 0.9$ kJ/kg K

$(u_2 - u_1)_{Al} = C_{v,Al}(T_2 - T_1) = 0.9(-10 - 20) = -27$ kJ/kg

$(s_2 - s_1)_{Al} = C_{p,Al} \ln(T_2/T_1) = 0.9 \ln(263.15/293.15) = -0.09716$ kJ/kg K

Table B.5.2: $v_1 = 0.04226$ m^3/kg, $u_1 = 390.5$ kJ/kg,

$s_1 = 1.7342$ kJ/kg K, $m_{R134a} = V/v_1 = 0.0473$ kg

$v_2 = v_1 = 0.04226$ & $T_2 \Rightarrow x_2 = (0.04226 - 0.000755)/0.09845 = 0.4216$

$u_2 = 186.57 + 0.4216 \times 185.7 = 264.9$ kJ/kg,

$s_2 = 0.9507 + 0.4216 \times 0.7812 = 1.2801$ kJ/kg K

${}_1Q_2 = 0.5 \times (-27) + 0.0473(264.9 - 390.5) = -19.44$ kJ

$${}_1S_{2\,gen} = 0.5\,(-0.09716) + 0.0473(1.2801 - 1.7342) + \frac{19.44}{263.15} = 0.003815 \text{ kJ/K}$$

${}_1I_2 = T_0\,({}_1S_{2\,gen}) = 263.15 \times 0.003815 =$ **1.0 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.49

R-134a is filled into an insulated 0.2 m^3 initially empty container from a line at 500 kPa, saturated vapor until the flow stops by itself. Find the final mass and temperature in the container and the total irreversibility in the process.

Solution:

C.V. Cannister filling process where: ${}_1Q_2 = \emptyset$; ${}_1W_2 = \emptyset$; $m_1 = \emptyset$

Continuity Eq.4.20: $m_2 - \emptyset = m_{in}$;

Energy Eq.4.21: $m_2u_2 - \emptyset = m_{in}h_{line} + \emptyset + \emptyset \quad \Rightarrow \quad u_2 = h_{line}$

Entropy Eq.7.13: $m_2s_2 - \emptyset = m_{in}s_{line} + \emptyset + {}_1S_{2\ gen}$

Inlet state: Table B.5.1 $h_{line} = 407.45$ kJ/kg, $s_{line} = 1.7198$ kJ/kg K

State 2: $P_2 = P_{line}$ and $u_2 = h_{line} = 407.45$ kJ/kg > $u_g \Rightarrow T_2 =$ **40°C**

$v_2 = 0.04656\ m^3/kg$, $s_2 = 1.7971$ kJ/kg K

$m_2 = V / v_2 = 0.2/0.04656 =$ **4.296 kg**

${}_1S_{2\ gen} = m_2(s_2 - s_{line}) = 4.296\ (1.7971 - 1.7198) =$ **0.332 kJ/K**

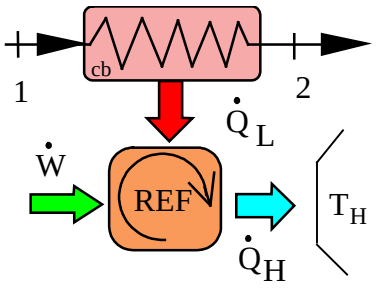
8.50

The water cooler in Problem 5.24 operates steady state. Find the rate of exergy destruction (irreversibility).



Energy equation for heat exchanger

$$\dot{Q}_L = \dot{m}(h_1 - h_2) = \dot{m}\, C_P\, (T_1 - T_2)$$
$$= 0.4 \text{ kg/s} \times 4.18 \text{ kJ/kg-K} \times (35 - 15) \text{ K}$$
$$= 33.44 \text{ kW}$$

$$\beta = \text{COP} = \dot{Q}_L / \dot{W} \quad \Rightarrow \quad \dot{W} = \dot{Q}_L / \beta = 33.44 / 3 = 11.15 \text{ kW}$$

Energy equation for the refrigerator

$$\dot{Q}_H = \dot{Q}_L + \dot{W} = 33.44 \text{ kW} + 11.15 \text{ kW} = 44.59 \text{ kW}$$

C.V. Total

Entropy Eq.: $0 = \dot{m}(s_1 - s_2) - \dot{Q}_H/T_H + \dot{S}_{gen}$

$$\dot{S}_{gen} = \dot{Q}_H/T_H - \dot{m}(s_1 - s_2) = \dot{Q}_H/T_H - \dot{m}C_p \ln(T_1/T_2)$$
$$= \frac{44.59 \text{ kW}}{298.15 \text{ K}} - 0.4 \text{ kg/s} \times 4.18 \text{ kJ/kg-K} \times \ln \frac{308.15}{288.15}$$
$$= 0.0857 \text{ kW/K}$$

$$\dot{I} = T_0\, \dot{S}_{gen} = 298.15 \text{ K} \times 0.0857 \text{ kW/K} = \mathbf{25.55 \text{ kW}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.51

Air enters the turbocharger compressor (see Fig. P8.51), of an automotive engine at 100 kPa, 30°C, and exits at 200 kPa. The air is cooled by 50°C in an intercooler before entering the engine. The isentropic efficiency of the compressor is 75%. Determine the temperature of the air entering the engine and the irreversibility of the compression-cooling process.

Solution:

a) Compressor. First ideal which is reversible adiabatic, constant s:

$$T_{2S} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 303.15\left(\frac{200}{100}\right)^{0.2857} = 369.5 \text{ K}$$

$$w_S = C_{P0}(T_1 - T_{2S}) = 1.004(303.15 - 369.5) = -66.565 \text{ kJ/kg}$$

Now the actual compressor

$$w = w_S/\eta_S = -66.565/0.75 = -88.75 \text{ kJ/kg} = C_P(T_1 - T_2)$$

$$\Rightarrow T_2 = 391.55 \text{ K}$$

$$T_3(\text{to engine}) = T_2 - \Delta T_{\text{INTERCOOLER}} = 391.55 - 50$$

$$= 341.55 \text{ K} = \mathbf{68.4°C}$$

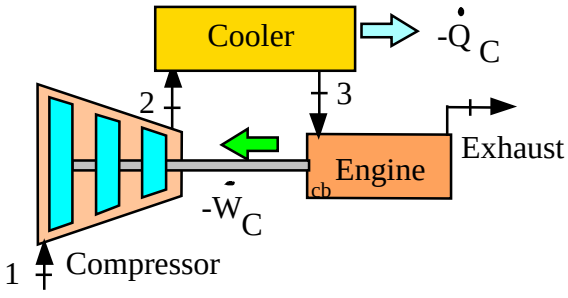
b) Irreversibility from Eq.8.15 with rev. work from Eq.8.14, ($q = 0$ at T_H)

$$s_3 - s_1 = 1.004 \ln\left(\frac{341.55}{303.15}\right) - 0.287 \ln\left(\frac{200}{100}\right) = -0.0792 \frac{\text{kJ}}{\text{kg K}}$$

$$i = T(s_3 - s_1) - (h_3 - h_1) - w \qquad [\, w^{rev} = (h_1 - Ts_1) - (h_3 - Ts_3) \,]$$

$$= T(s_3 - s_1) - C_P(T_3 - T_1) - C_P(T_1 - T_2)$$

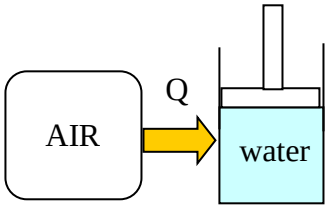
$$= 303.15(-0.0792) - 1.004(-50) = \mathbf{+26.2 \text{ kJ/kg}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.52

A constant pressure piston/cylinder has 1 kg of saturated liquid water at 100 kPa. A rigid tank contains air at 1000 K, 1000 kPa. They are now thermally connected by conduction through the walls cooling the air tank and bringing the water to saturated vapor. Find the required amount of air and the irreversibility of the process assuming no external heat transfer.



State: 1 = initial air
2 = final air
3 = initial water
4 = final water we assume $T_4 = T_2$

Take CV as each of the masses. This gives Q from the two energy equations.

$$Q = m_{H2O}(u_4 - u_3) + W_{H2O} = m_{H2O}(h_4 - h_3) = m_{H2O}\, h_{fg} = 2258.02 \text{ kJ}$$

$$Q = -m_{air}(u_2 - u_1) = -m_{air}\, C_v\, (T_2 - T_1)$$

$$m_{air} = m_{H2O}\, h_{fg} / C_v\, (T_1 - T_2) = \frac{2258.02}{0.717\ (1000 - 372.77)} = \mathbf{5.0209\ kg}$$

The entropy equation Eq.8.37 for an irreversible process becomes

$$(S_2 - S_1)_{tot} = m_{air}(s_2 - s_1) + m_{H2O}(s_4 - s_3) = 0 + {}_1S_{2\,gen}$$

$$m_{H2O}(s_4 - s_3) = m_{H2O}\, s_{fg} = 1 \text{ kg} \times 6.0568 \text{ kJ/kg-K} = 6.0568 \text{ kJ/K}$$

$$s_2 - s_1 = C_v \ln \frac{T_2}{T_1} + R \ln \frac{v_2}{v_1} = C_v \ln \frac{T_2}{T_1} = 0.717 \ln \frac{372.77}{1000} = -0.70753 \frac{\text{kJ}}{\text{kg-K}}$$

Now solve for the entropy generation

$${}_1S_{2\,gen} = m_{air}(s_2 - s_1) + m_{H2O}(s_4 - s_3)$$

$$= 5.0209\ (-0.70753) + 6.0568 = 2.5044 \text{ kJ/K}$$

$${}_1I_2 = T_0\ (\ {}_1S_{2\,gen}\ ) = 298.15 \times 2.5044 = \mathbf{746.6\ kJ}$$

Exergy

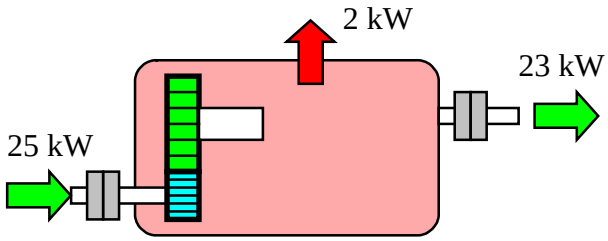
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.53

The automatic transmission in a car receives 25 kW shaft work and gives out 23 kW to the drive shaft. The balance is dissipated in the hydraulic fluid and metal casing, all at 45°C, which in turn transmits it to the outer atmosphere at 20°C. Find all the exergy transfer rates.

Solution:

C.V. Total unit. Steady state and surface at 45°C



Exergy transfer:

$$\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H; \qquad \dot{\Phi}_W = \dot{W};$$

The two shaft works are 100% exergy

$$\dot{\Phi}_W = \dot{W} = 25 \text{ kW} \quad \text{coming in and} \quad \dot{\Phi}_W = \dot{W} = 23 \text{ kW} \quad \text{leaving}$$

The remaingning balance of energy leaves as heat transfer from the 45°C surface

$$\dot{\Phi}_{\text{out with Q}} = \left(1 - \frac{T_o}{T_{\text{Surface}}}\right) \dot{Q}_{\text{out}} = \left(1 - \frac{293.15}{273.15 + 45}\right) 2 \text{ kW} = \mathbf{0.157\ kW}$$

Here we used 293.15 for the reference T as it was the ambient. Once the heat transfer is redistributed at the ambient T the exergy transfer is zero.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

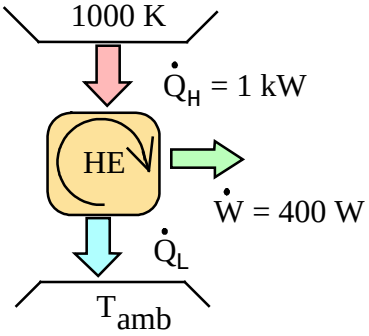
8.54

A heat engine receives 1 kW heat transfer at 1000 K and gives out 400 W as work with the rest as heat transfer to the ambient. What are the fluxes of exergy in and out?

Exergy flux in: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H = \left(1 - \frac{298.15}{1000}\right) 1 \text{ kW} =$ **0.702 kW**

Exergy flux out: $\dot{\Phi}_L = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L =$ **0** $\quad (T_L = T_o)$

The other exergy flux out is the power $\dot{\Phi}_{out} = \dot{W} =$ **0.4 kW**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

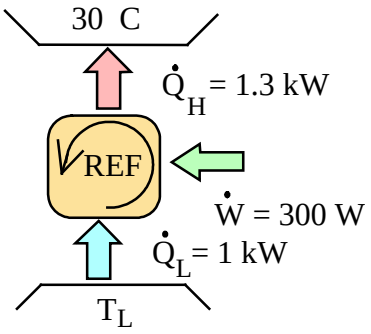
8.55

In a refrigerator 1 kW is removed from the -10^{o}C cold space and 1.3 kW is moved into the 30^{o}C warm space. Find the exergy fluxes including direction associated with the two heat transfers.

$$\dot{\Phi}_H = (1 - \frac{T_o}{T_H})\,\dot{Q}_H = (1 - \frac{298.15}{303.15})\ 1.3\ \text{kW} = \mathbf{0.021\ kW}$$

$$\dot{\Phi}_L = (1 - \frac{T_o}{T_L})\,\dot{Q}_L = (1 - \frac{298.15}{263.15})\ 1\ \text{kW} = \mathbf{-0.133\ kW}$$

I.e. the flux goes into the cold space! Why? As you cool it $T < T_o$ and you increase its exergy, it is further away from the ambient.



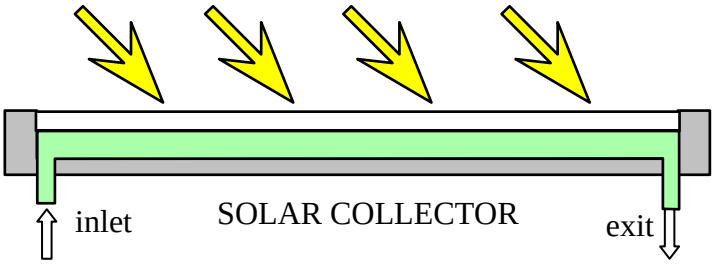
The refrigerator gives 0.133 kW of exergy to the cold space and 0.021 kW to the hot space in terms of exergy driven by a work input of $\dot{W} = (1.3 - 1) = 0.3$ kW that is a second law efficiency of about 50%.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.56

A steady stream of R-410A at ambient temperature, 20°C and 800 kPa enters a solar collector and it exits at 80°C, 600 kPa. Calculate the change in exergy of the R410a.

Solution:



Inlet (T,P) Table B.4.2: $h_i = 300.02$ kJ/kg, $s_i = 1.1105$ kJ/kg K

Exit (T,P) Table B.4.2: $h_e = 359.67$ kJ/kg, $s_e = 1.3265$ kJ/kg K

From Eq.8.23 or flow terms in Eq.8.38

$$\Delta\psi_{ie} = \psi_e - \psi_i = (h_e - h_i) - T_0(s_e - s_i) = (359.67 - 300.02)$$
$$- 293.15(1.3265 - 1.1105) = \mathbf{-3.67\ kJ/kg}$$

Remark: it is negative due to the pressure loss.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.57

A heat pump has a coefficient of performance of 2 using a power input of 3 kW. Its low temperature is T_o and the high temperature is 80°C, with an ambient at T_o. Find the fluxes of exergy associated with the energy fluxes in and out.

First let us do the energies in and out

$$\text{COP} = \beta = \frac{\dot{Q}_H}{\dot{W}} \quad \Rightarrow \quad \dot{Q}_H = \beta\, \dot{W} = 2 \times 3 \text{ kW} = 6 \text{ kW}$$

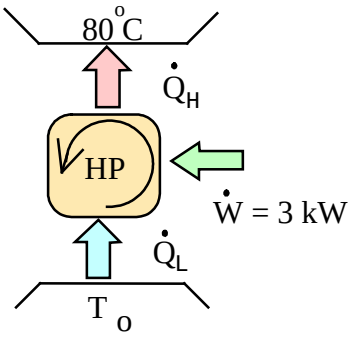
Energy Eq.: $\dot{Q}_L = \dot{Q}_H - \dot{W} = 6 - 3 = 3$ kW

Exergy flux in: $\dot{\Phi}_L = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L = \mathbf{0}$ $\quad (T_L = T_o)$

Exergy flux in: $\dot{\Phi}_W = \dot{W} = \mathbf{3\ kW}$

Exergy flux out: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H = \left(1 - \frac{298.15}{353.15}\right) 6 \text{ kW} = \mathbf{0.935\ kW}$

Remark: The process then destroys (3 – 0.935) kW of exergy.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.58

A flow of air at 1000 kPa, 300 K is throttled to 500 kPa. What is the irreversibility? What is the drop in flow exergy?

A throttle process is constant enthalpy if we neglect kinetic energies.

Process: $h_e = h_i$ so ideal gas => $T_e = T_i$

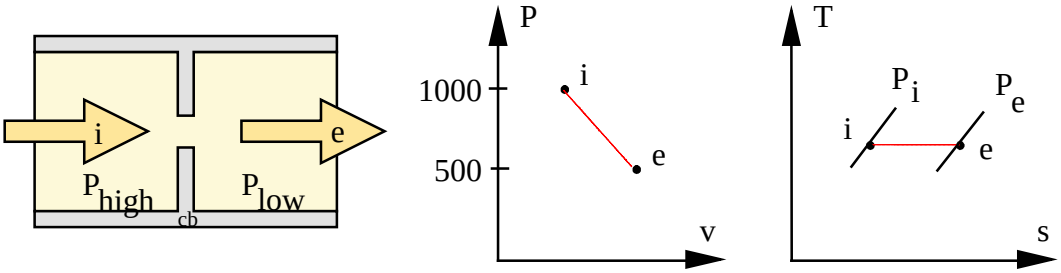
Entropy Eq.: $s_e - s_i = s_{gen} = s^o_{Te} - s^o_{Ti} - R \ln \frac{P_e}{P_i} = 0 - R \ln \frac{P_e}{P_i}$

$$s_{gen} = - 0.287 \ln (500 / 1000) = 0.2 \text{ kJ/kg K}$$

Eq.8.15: $i = T_o s_{gen} = 298\ 0.2 =$ **59.6 kJ/kg**

The drop in exergy is exergy destruction, which is the irreversibility

$$\Delta\psi = i = \textbf{59.6 kJ/kg}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.59

A power plant has an overall thermal efficiency of 40% receiving 100 MW of heat transfer from hot gases at an average of 1300 K and rejects heat transfer at 50°C from the condenser to a river at ambient temperature 20°C. Find the rate of both energy and exergy a) from the hot gases and b) from the condenser.

C.V. High T heat exchanger.

Energy flux in: $\dot{Q}_H = 100$ MW

Exergy flux in: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H = \left(1 - \frac{293.15}{1300}\right) 100 \text{ MW} =$ **77.45 MW**

C.V. condenser.

Overall power plant: $\dot{W} = \eta \dot{Q}_H$ so from energy equation

Energy flux out $\dot{Q}_L = \dot{Q}_H - \dot{W} = (1 - \eta)\, \dot{Q}_H = 0.6 \times 100 \text{ MW} =$ **60 MW**

Exergy flux out: $\dot{\Phi}_L = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L = \left(1 - \frac{293.15}{323.15}\right) 60 \text{ MW} =$ **5.57 MW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.60

Find the change in exergy from inlet to exit of the condenser in Problem 7.48.

Solution:

Condenser of Prob. 7.48 has inlet equal to turbine exit.

State 2: $P_2 = 20$ kPa; $s_2 = s_1 = 6.7993$ kJ/kg K

$$\Rightarrow \quad x_2 = (6.7993 - 0.8319)/7.0766 = 0.8433$$

$$h_2 = 2240.1 \text{ kJ/kg}$$

State 3: $P_2 = P_3$; $T_3 = 40°C$; Compressed liquid assume sat.liq. same T

Table B.1.1 $h_3 = 167.5$ kJ/kg; $s_3 = 0.5724$ kJ/kg K

From Eq.8.23 or from flow terms in Eq.8.38

$$\psi_3 - \psi_2 = (h_3 - T_o s_3) - (h_2 - T_o s_2)$$

$$= (h_3 - h_2) - T_o(s_3 - s_2)$$

$$= (167.5 - 2240.1) - 298.2(0.5724 - 6.7993)$$

$$= -2072.6 + 1856.9 = \mathbf{-215.7 \text{ kJ/kg}}$$

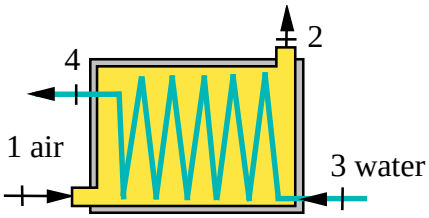
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.61

Calculate the change in exergy (kW) of the two flows in Problem 7.105.

Solution:

The two flows in the heat exchanger exchanges energy and thus also exergy (exergy). Fist find state 4



Air A.7: $h_1 = 1046.22$, $h_2 = 401.3$ kJ/kg,

$s^o_{T1} = 8.1349$, $s^o_{T2} = 7.1593$ kJ/kg K

Water B.1.1: $h_3 = 83.94$ kJ/kg, $s_3 = 0.2966$ kJ/kg K

Energy Eq.6.10: $\dot{m}_{AIR}\Delta h_{AIR} = \dot{m}_{H2O}\Delta h_{H2O}$

$h_4 - h_3 = (\dot{m}_{AIR}/\dot{m}_{H2O})(h_1 - h_2) = (2/0.5)644.92 = 2579.68$ kJ/kg

$h_4 = h_3 + 2579.68 = 2663.62 \quad < \quad h_g$ at 200 kPa

$T_4 = T_{sat} = 120.23°C$,

$x_4 = (2663.62 - 504.68)/2201.96 = 0.9805$,

$s_4 = 1.53 + x_4\, 5.597 = 7.01786$ kJ/kg K

We consider each flow separately and for each flow exergy is Eq.8.23, include mass flow rate as in Eq.8.38, use $T_o = 20$ C

For the air flow:

$$\dot{m}_1(\psi_1 - \psi_2) = \dot{m}_1 [\, h_1 - h_2 - T_o (\, s_1 - s_2 \,) \,]$$

$$= 2 [\, 1046.22 - 401.3 - 293.2(8.1349 - 7.1593 - 0.287 \ln \frac{125}{100})]$$

$$= 2\,(644.92 - 267.22\,) = \mathbf{755.4\ kW}$$

For the water flow:

$$\dot{m}_3(\psi_4 - \psi_3) = \dot{m}_3 [\, h_4 - h_3 - T_o (\, s_4 - s_3 \,) \,]$$

$$= 0.5 [\, 2663.62 - 83.94 - 293.2(7.01786 - 0.2966)]$$

$$= 0.5[\, 2579.68 - 1970.7\,] = \mathbf{304.7\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.62

A steady-flow device receives R-410A at 40^{o}C, 800 kPa and it exits at 40^{o}C, 100 kPa. Assume a reversible isothermal process. Find the change in specific exergy.

C.V. The steady flow device assume $T_0 = 25^{o}$C

Inlet (T,P) Table B.4.2: $h_i = 319.42$ kJ/kg, $s_i = 1.1746$ kJ/kg K

Exit (T,P) Table B.4.2: $h_e = 330.12$ kJ/kg, $s_e = 1.4380$ kJ/kg K

From Eq.8.22 or 10.23

$$\Delta\psi_{ie} = \psi_e - \psi_i = (h_e - h_i) - T_0(s_e - s_i) = (330.12 - 319.42)$$

$$- 298.2(1.4380 - 1.1746) = \mathbf{-67.85\ kJ/kg}$$

The device is like an expander, P drops so work is out and s increases so heat transfer comes in.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.63

Consider the springtime melting of ice in the mountains, which gives cold water running in a river at 2°C while the air temperature is 20°C. What is the exergy of the water relative to the temperature of the ambient?
Solution:

$\psi = h_1 - h_0 - T_0(s_1 - s_0)$ flow exergy from Eq.8.22

Approximate both states as saturated liquid from Table B.1.1

ψ = 8.392 - 83.96 - 293.15(0.03044 - 0.2966) = **2.457 kJ/kg**

Why is it positive? As the water is brought to 20°C it can be heated with q_L from a heat engine using q_H from atmosphere $T_H = T_0$ thus giving out work.

Clip-art from Microsoft.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.64

Nitrogen flows in a pipe with velocity 300 m/s at 500 kPa, 300°C. What is its exergy with respect to an ambient at 100 kPa, 20°C?

Solution:
From the exergy or exergy in Eq.8.22

$$\psi = h_1 - h_0 + (1/2)\mathbf{V}_1^2 - T_0(s_1 - s_0)$$

$$= C_p(T_1 - T_0) + (1/2)\mathbf{V}_1^2 - T_0\left[C_p \ln\left(\frac{T_1}{T_0}\right) - R \ln\left(\frac{P_1}{P_0}\right)\right]$$

$$= 1.042(300 - 20) + \frac{300^2}{2000} - 293.15\left(1.042 \ln\left(\frac{573.15}{293.15}\right) - 0.2968 \ln\left(\frac{500}{100}\right)\right)$$

$$= \mathbf{272\ kJ/kg}$$

Notice that the high velocity does give a significant contribution.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.65

Compressed air for machines and tools in a plant is generated by a central compressor receiving air at 100 kPa, 300 K, 1 kg/s delivering it at 600 kPa to a buffer tank and a distribution pipe. After flowing through the tank and pipe the air is at the ambient 300 K at its point of use. Assume a reversible adiabatic compressor and find the compressor exit temperature and the increase in air exergy through the compressor.

C.V. Compressor

Energy: $0 = h_1 - h_2 + w_C$; Entropy: $0 = s_1 - s_2 + 0$

$$s_2 - s_1 = s^0_{T2} - s^0_{T1} - R \ln(P_2/P_1) \quad \text{find } s^0_{T2} \text{ and then } T_2$$

or with constant specific heat

$$T_2 = T_1 \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300 \left(\frac{600}{100}\right)^{0.2857} = \mathbf{500.5\ K}$$

Exergy increase through the compressor matches with the compressor work

$$\psi_2 - \psi_1 = (h_2 - h_1) - T_0(s_2 - s_1) = h_2 - h_1 = C_P (T_2 - T_1) = w_C$$

$$= 1.004 \text{ kJ/kgK } (500.5 - 300) \text{ K} = \mathbf{201.3\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.66

For the air system in the previous problem find the increase in the air exergy from the inlet to the point of use. How much exergy was lost in the flow after the compressor exit?

From inlet, state 1 to final point of use state 3.

$$\psi_3 - \psi_1 = (h_3 - h_1) - T_0(s_3 - s_1) = 0 - T_0[0 - R \ln(P_3/P_1)]$$
$$= T_0 R \ln(P_3/P_1) = 298.15 \text{ K} \times 0.287 \text{ kJ/kgK} \times \ln (600/100)$$
$$= \mathbf{153.3 \text{ kJ/kg}}$$

Compressor exit, reversible adiabatic, constant s process: $s_2 = s_1$

$$T_2 = T_1 \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300 \left(\frac{600}{100}\right)^{0.2857} = 500.5 \text{ K}$$

So then

$$\psi_{lost} = \psi_2 - \psi_3 = -(\psi_3 - \psi_1) + (\psi_2 - \psi_1) = -(\psi_3 - \psi_1) + h_2 - h_1$$
$$= -(\psi_3 - \psi_1) + C_{P0}(T_2 - T_1)$$
$$= -153.3 \text{ kJ/kg} + 1.004 \text{ kJ/kgK} \times (500.5 - 300) \text{ K}$$
$$= \mathbf{48 \text{ kJ/kg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.67

Calculate the exergy of the water at the initial and final states of Problem 6.130, and the irreversibility of the process.

State properties

1: $u_1 = 83.94$ kJ/kg, $s_1 = 0.2966$ kJ/kg K, , $v_1 = 0.001$ m^3/kg

2: $u_2 = 3124.3$ kJ/kg, $s_2 = 7.7621$ kJ/kg K, $v_2 = 0.354$ m^3/kg

0: $u_o = 104.86$ kJ/kg, $s_o = 0.3673$ kJ/kg K, $v_o = 0.001003$ m^3/kg

Process transfers: ${}_1W_2^{ac} = 203$ kJ, ${}_1Q_2^{ac} = 3243.4$ kJ, $T_H = 873.15$ K

$\phi = (u - T_o s) - (u_o - T_o s_o) + P_o(v - v_o)$

$\phi_1 = (83.94 - 298.15\times0.2966) - (104.86 - 298.15\times0.3673)$

$+ 100\ (0.001002 - 0.001003) = 0.159$ kJ/kg

$\phi_2 = (3124.3 - 298.15\times7.7621) - (104.86 - 298.15\times0.3673)$

$+ 100\ (0.35411 - 0.001003) = 850$ kJ/kg

${}_1I_2 = m(\phi_1 - \phi_2) + [1 - (T_o/T_H)]{}_1Q_2^{ac} - {}_1W_2^{ac} + P_o(V_2 - V_1)$

$= -849.84 + (1 - \frac{298.15}{873.15}) 3243.4 - 203 + 100\ (0.3541 - 0.001)$

$= -849.84 + 2135.9 - 203 + 35.31 =$ **1118 kJ**

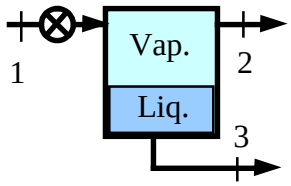
[($S_{gen} = 3.75$ kJ/K; $T_o S_{gen} = 1118$ kJ so OK]

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.68

A geothermal source provides 10 kg/s of hot water at 500 kPa, 145°C flowing into a flash evaporator that separates vapor and liquid at 200 kPa. Find the three fluxes of exergy (inlet and two outlets) and the irreversibility rate.

C.V. Flash evaporator chamber. Steady flow with no work or heat transfer.



Cont. Eq.: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$;

Energy Eq.: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3$

Entropy Eq.: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3$

B.1.1: $h_o = 104.87$, $s_o = 0.3673$, B.1.4: $h_1 = 610.7$, $s_1 = 1.7902$

B.1.2: $h_2 = 2706.63$, $s_2 = 7.1271$, $h_3 = 504.68$, $s_3 = 1.530$

$$h_1 = x h_2 + (1 - x) h_3 \quad \Rightarrow \quad x = \dot{m}_2/\dot{m}_1 = \frac{h_1 - h_3}{h_2 - h_3} = 0.04815$$

$$\dot{m}_2 = x\dot{m}_1 = 0.4815 \text{ kg/s} \qquad \dot{m}_3 = (1-x)\dot{m}_1 = 9.5185 \text{ kg/s}$$

$$\dot{S}_{gen} = 0.4815 \times 7.1271 + 9.5185 \times 1.53 - 10 \times 1.7902 = 0.093 \text{ kW/K}$$

Flow exergy Eq.8.22: $\psi = (h - T_o s) - (h_o - T_o s_o) = h - h_o - T_o(s - s_o)$

$$\psi_1 = 610.7 - 104.87 - 298.15\,(1.7902 - 0.3673) = 81.59 \text{ kJ/kg}$$

$$\psi_2 = 2706.63 - 104.87 - 298.15\,(7.1271 - 0.3673) = 586.33 \text{ kJ/kg}$$

$$\psi_3 = 504.68 - 104.87 - 298.15\,(1.53 - 0.3673) = 53.15 \text{ kJ/kg}$$

$\dot{m}_1 \psi_1 =$ **815.92 kW** $\dot{m}_2\psi_2 =$ **282.3 kW** $\dot{m}_3\psi_3 =$ **505.9 kW**

Balance of flow terms in Eq.8.38

$$\dot{I} = \dot{m}_1 \psi_1 - \dot{m}_2 \psi_2 - \dot{m}_3\psi_3 = \textbf{27.7 kW} \quad (= T_o \dot{S}_{gen})$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.69

An air compressor is used to charge an initially empty 200-L tank with air up to 5 MPa. The air inlet to the compressor is at 100 kPa, 17°C and the compressor isentropic efficiency is 80%. Find the total compressor work and the change in exergy of the air.

C.V. Tank + compressor Transient process with constant inlet conditions, no heat transfer.

Continuity: $m_2 - m_1 = m_{in}$ ($m_1 = 0$) Energy: $m_2u_2 = m_{in}h_{in} - {}_1W_2$

Entropy: $m_2s_2 = m_{in}s_{in} + {}_1S_{2\,gen}$

Reversible compressor: ${}_1S_{2\,GEN} = 0 \quad \Rightarrow \; s_2 = s_{in}$

State 1: $v_1 = RT_1/P_1 = 0.8323\ m^3/kg$, the ambient state

State inlet, Table A.7.1: $h_{in} = 290.43$ kJ/kg, $s^o_{Tin} = 6.83521$ kJ/kg K

Eq.6.19: $s^o_{T2} = s^o_{Tin} + R \ln \left(\frac{P_2}{P_{in}}\right) = 6.83521 + 0.287 \ln \left(\frac{5000}{100}\right) = 7.95796$

Table A.7.1 $\Rightarrow$ $T_{2,s} = 854.6$ K, $u_{2,s} = 637.25$ kJ/kg

$\Rightarrow {}_1w_{2,s} = h_{in} - u_{2,s} = 290.43 - 637.25 = -346.82$ kJ/kg

Actual compressor: ${}_1w_{2,AC} = {}_1w_{2,s}/\eta_c = -433.53$ kJ/kg

$u_{2,AC} = h_{in} - {}_1w_{2,AC} = 290.43 - (-433.53) = 723.96$ kJ/kg

$\Rightarrow T_{2,AC} = 958.5$ K, $s^o_{T2\,ac} = 8.08655$ kJ/kg K

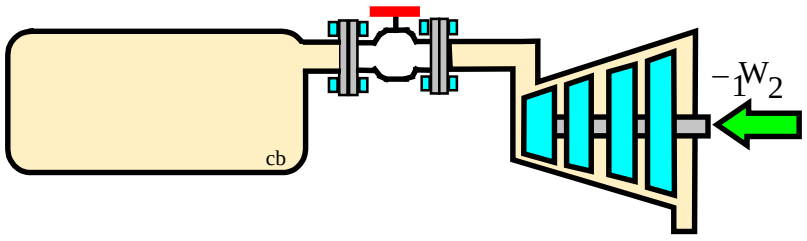
State 2 $\boxed{u, P}$ $v_2 = RT_2/P_2 = 0.05502\ m^3/kg$ so $m_2 = V_2/v_2 = 3.635$ kg

$\Rightarrow {}_1W_2 = m_2\,({}_1w_{2,AC}) =$ **-1575.9 kJ**

$m_2(\phi_2 - \phi_1) = m_2[u_2 - u_1 + P_0(v_2 - v_1) - T_0(s_2 - s_1)]$

$= 3.635\,[723.96 - 207.19 + 100(0.05502 - 0.8323) - 290[8.08655 -$

$6.83521 - 0.287 \ln(5000/100)] =$ **1460.4 kJ**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.70

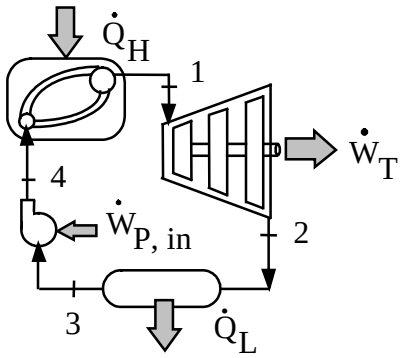
Find the exergy at all 4 states in the power plant of Problem 7.48 with an ambient at 298 K.

Solution:

Flow exergy from Eq.8.22 neglecting kinetic and potential energy is:

$$\psi = h - h_0 - T_0(s - s_0)$$

so we need (h,s) for all four states.



$P_1 = P_4 = 20$ MPa, $T_1 = 700$ °C

$h_1 = 3809.1$ kJ/kg,

$s_1 = 6.7993$ kJ/kg K

$P_2 = P_3 = 20$ kPa, $T_3 = 40$ °C

State 3: (P, T) Comp. liquid, take sat. liquid Table B.1.1

$h_3 = 167.5$ kJ/kg,

$v_3 = 0.001008$ m^3/kg

C.V. Turbine.

Entropy Eq.7.8: $s_2 = s_1 = 6.7993$ kJ/kg K

Table B.1.2 $s_2 = 0.8319 + x_2 \times 7.0766$ => $x_2 = 0.8433$

$h_2 = 251.4 + 0.8433 \times 2358.33 = 2240.1$ kJ/kg

$w_T = h_1 - h_2 = 3809.1 - 2240.1 = 1569$ kJ/kg

CV. Pump, property relation v = constant gives work from Eq.7.15 as

$w_P = - v_3(P_4 - P_3) = -0.001008(20000 – 20) = -20.1$ kJ/kg

$h_4 = h_3 - w_P = 167.5 + 20.1 = 187.6$ kJ/kg

Flow exergy from Eq.8.23 and notice that since turbine work and pump work are reversible they represent also change in avalability.

$\psi_1 = h_1 - h_0 - T_0(s_1 - s_0) = 3809.1 – 104.87 - 298 (6.7993 – 0.3673)$

$= \mathbf{1787.5\ kJ/kg}$

$\psi_2 = h_2 - h_0 - T_0(s_2 - s_0) = \psi_1 - w_T = 1787.5 - 1569 = \mathbf{218.5\ kJ/kg}$

$\psi_3 = h_3 - h_0 - T_0(s_3 - s_0) = 167.5 - 104.87 - 298(0.5724 - 0.3673)$

$= \mathbf{1.51\ kJ/kg}$

$\psi_4 = h_4 - h_0 - T_0(s_4 - s_0) = \psi_3 - w_P = 1.51 + 20.1 = \mathbf{21.61\ kJ/kg}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.71

An electric stove has one heating element at 300°C getting 750 W of electric power. It transfers 90% of the power to 1 kg water in a kettle initially at 20°C, 100 kPa, the rest 10% leaks to the room air. The water at a uniform T is brought to the boiling point. At the start of the process what is the rate of exergy transfer by: a) electrical input b) from heating element and c) into the water at T_{water}.

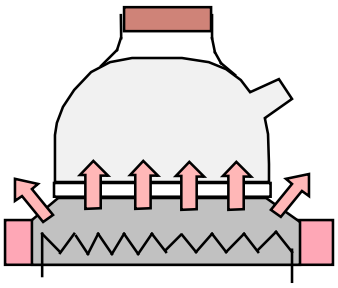
a) Work is exergy $\dot{\Phi} = \dot{W} =$ **750 W**

b) Heat transfer at 300°C is only partly exergy

$$\dot{\Phi} = \left(1 - \frac{T_o}{T_H}\right)\dot{Q} = \left(1 - \frac{293.15}{273.15 + 300}\right) 750 = \mathbf{366\ W}$$

c) Water receives heat transfer at 20°C as 90% of 750 W = 675 W

$$\dot{\Phi} = \left(1 - \frac{T_o}{T_{water}}\right)\dot{Q} = \left(1 - \frac{293.15}{273.15 + 20}\right) 675 = \mathbf{0\ W}$$



750 W at 300°C

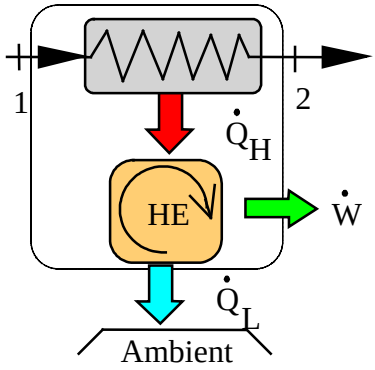
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.72

Air flows at 1500 K, 100 kPa through a constant pressure heat exchanger giving energy to a heat engine and comes out at 500 K. What is the constant temperature the same heat transfer should be delivered at to provide the same exergy?

Solution:

C.V. Heat exchanger



Continuity eq.: $\dot{m}_1 = \dot{m}_2$;

Energy Eq.4.12: $\dot{m}_1 h_1 = \dot{m}_1 h_2 + \dot{Q}_H$

Table A.7.1: $h_1 = 1635.8$ kJ/kg,

$h_2 = 503.36$ kJ/kg, $s_1 = 8.61209$ kJ/kg K

$s_2 = 7.38692$ kJ/kg K

$q_{out} = h_1 - h_2 = 1635.8 - 503.36 = 1132.4$ kJ/kg

Exergy from heat transfer at T: $\Delta\psi = (1 - \frac{T_o}{T_H})\, q_{out} = \psi_1 - \psi_2$

Eq.8.23 and the flow terms per unit mass flow in Eq.8.38:

$$\psi_1 - \psi_2 = h_1 - h_2 - T_o (s_1 - s_2)$$

$$= 1132.4 - 298.15\ (8.6121 - 7.38692)$$

$$= 1132.4 - 356.3 = 767.1 \text{ kJ/kg}$$

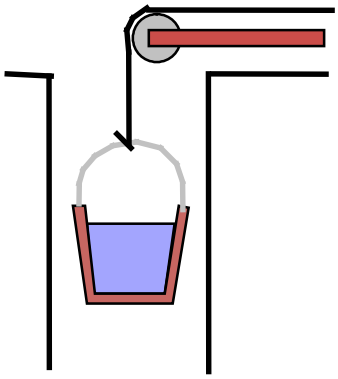
$$1 - \frac{T_o}{T_H} = (\psi_1 - \psi_2) / q_{out} = 767.1 / 1132.4 = 0.6774$$

$$\frac{T_o}{T_H} = 0.3226 \ \Rightarrow \quad \mathbf{T_H = 924\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.73

A wooden bucket (2 kg) with 10 kg hot liquid water, both at 85°C, is lowered 400 m down into a mineshaft. What is the exergy of the bucket and water with respect to the surface ambient at 20°C?



C.V. Bucket and water. Both thermal exergy and potential energy terms.

$v_1 \approx v_0$ for both wood and water so work to atm. is zero.

Use constant heat capacity table A.3 for wood and table B.1.1 (sat. liq.) for water.
From Eq.8.28

$$\phi_1 - \phi_0 = m_{wood}[u_1 - u_0 - T_0(s_1 - s_0)] + m_{H_2O}[u_1 - u_0 - T_0(s_1 - s_0)] + m_{tot}g(z_1 - z_0)$$

$$= 2 \text{ kg } [1.26 \frac{\text{kJ}}{\text{kg K}} (85 - 20) \text{ K} - 293.15 \text{ K} \times 1.26 \frac{\text{kJ}}{\text{kg K}} \times \ln \frac{273.15 + 85}{293.15}]$$

$$+ 10 \text{ kg } [355.82 - 83.94 - 293(1.1342 - 0.2966)] \text{ kJ/kg}$$

$$+ 12 \text{ kg} \times 9.807 \text{ (m/s}^2\text{)} \times (-400) \text{ m } /1000 \text{ (J/kJ)}$$

$$= 15.85 + 263.38 - 47.07 = \mathbf{232.2 \text{ kJ}}$$

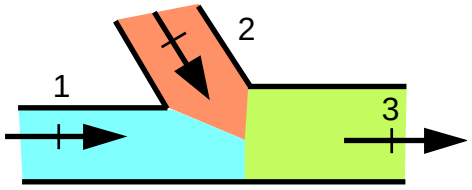
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.74

A flow of 0.1 kg/s hot water at 70°C is mixed with a flow of 0.2 kg/s cold water at 20°C in a shower fixture. What is the rate of exergy destruction (irreversibility) for this process?

Solution:

Continuity Eq.4.9:



$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3$$

$$= 0.1 + 0.2 = 0.3 \text{ kg/s}$$

Energy Eq.4.10:

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen} = \dot{m}_3 s_3$

Use specific heat from A.4 and Eq.6.11 for s change or Table B.1.1 saturated liquid values. Divide the energy equation with $\dot{m}_3 C_P$

$$T_3 = (\dot{m}_1/\dot{m}_3)T_1 + (\dot{m}_2/\dot{m}_3)T_2 = \frac{1}{3} \times 70 + \frac{2}{3} \times 20 = 36.67^{\circ}\text{C}$$

$$\dot{S}_{gen} = \dot{m}_1(s_3 - s_1) + \dot{m}_2(s_3 - s_2)$$

$$= 0.1 \times 4.18 \ln (309.82/343.15) + 0.2 \times 4.18 \ln (309.82/293.15)$$

$$= 0.00353 \text{ kW/K}$$

$$\dot{\Phi}_{Destruction} = \dot{I} = T_o \dot{S}_{gen} = 298.15 \times 0.00353 = \mathbf{1.05\ kW}$$

You could also have decided to use 20°C for the ambient T in this problem.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.75

A 1 kg block of copper at 350°C is quenched in a 10 kg oil bath initially at ambient temperature of 20°C. Calculate the final uniform temperature (no heat transfer to/from ambient) and the change of exergy of the system (copper and oil).

Solution:

C.V. Copper and oil. $C_{co} = 0.42$ kJ/kg K, $C_{oil} = 1.8$ kJ/kg K

$$m_2u_2 - m_1u_1 = {}_1Q_2 - {}_1W_2 = 0 = m_{co}C_{co}(T_2 - T_1)_{co} + (mC)_{oil}(T_2 - T_1)_{oil}$$

$$1 \times 0.42 \, (T_2 - 350) + 10 \times 1.8 \, (T_2 - 20) = 0$$

$$18.42 \, T_2 = 507 \quad \Rightarrow \quad T = 27.5°C = 300.65 \text{ K}$$

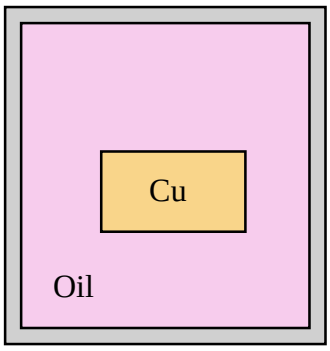
For each mass copper and oil, we neglect work term (v = C) so Eq.8.28 is

$$(\phi_2 - \phi_1) = u_2 - u_1 - T_o(s_2 - s_1) = mC \, [(T_2 - T_1) - T_o \ln (T_2 / T_1)]$$

$$m_{cv}(\phi_2 - \phi_1)_{cv} + m_{oil} \, (\phi_2 - \phi_1)_{oil} =$$

$$= 0.42 \times [(-322.5) - 293.15 \ln \frac{300.65}{623.15}] + 10 \times 1.8 \, [7.5 - 293.15 \ln \frac{300.65}{293.15}]$$

$$= - 45.713 + 1.698 = \mathbf{- 44.0 \text{ kJ}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.76

A water kettle has 1 kg of saturated liquid water at P_o. It is on an electric stove that heats it from a hot surface at 500 K. Water vapor escapes from the kettle and when the last liquid drop disappears the stove is turned off. Find the destruction of exergy two places: a) between the hot surface and the water and b) between the electrical wire input and the hot surface.

C.V. The water, this is a control mass. We bring it from saturated liquid to saturated vapor same pressure.

Energy eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2 \Rightarrow {}_1Q_2 = m\,(h_2 - h_1) = mh_{fg} = 2257$ kJ

C.V. Kettle bottom, consider the hot surface to water heat transfer.

$$\psi_{in} = \left(1 - \frac{T_o}{T_{H\ surface}}\right) {}_1Q_2 = \left(1 - \frac{298.15}{500}\right) 2257\ \text{kJ} = 911\ \text{kJ}$$

$$\psi_{out} = \left(1 - \frac{T_o}{T_{water}}\right) {}_1Q_2 = \left(1 - \frac{298.15}{373.15}\right) 2257\ \text{kJ} = 453.6\ \text{kJ}$$

The destruction is the drop in exergy

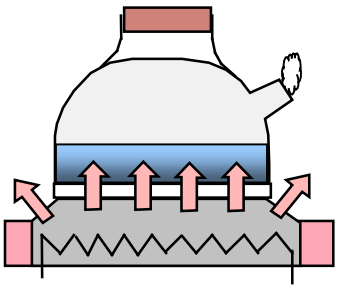
$$\psi_{destruction} = \psi_{in} - \psi_{out} = 911 - 453.6 = \mathbf{457.4\ kJ}$$

C.V. Wire and hot plate.

$$\psi_{in} = W_{electrical} = {}_1Q_2 = 2257\ \text{kJ}$$

$$\psi_{out} = \left(1 - \frac{T_o}{T_{H\ surface}}\right) {}_1Q_2 = \left(1 - \frac{298.15}{500}\right) 2257\ \text{kJ} = 911\ \text{kJ}$$

$$\psi_{destruction} = \psi_{in} - \psi_{out} = 2257 - 911 = \mathbf{1346\ kJ}$$



Comment: We could also have found the destruction of exergy by finding the entropy generation terms and then $\psi_{destruction} = T_o\, S_{gen}$

8.77

A 200 L insulated tank contains nitrogen gas at 200 kPa, 300 K. A line with nitrogen at 500 K, 500 kPa adds 40% more mass to the tank with a flow through a valve. Use constant specific heats to find the final temperature and the exergy destruction.

C.V. Tank, no work and no heat transfer.

Continuity Eq.4.20: $m_2 - m_1 = m_i$

Energy Eq.4.21: $m_2 u_2 - m_1 u_1 = m_i h_i + {}_1Q_2$

Entropy Eq.7.12: $m_2 s_2 - m_1 s_1 = m_i s_i + \int dQ/T + {}_1S_{2\,gen}$

Process Eq.: ${}_1Q_2 = 0, \quad m_2 = 1.4\, m_1; \quad m_i = 0.4\, m_1$

Write $h_i = u_i + RT_i$ then the energy equation contains only u's so we can substitute the u differences with $C_{v0}\,\Delta T$ and divide by $m_2\, C_{v0}$ to get

$$T_2 = \frac{m_1}{m_2} T_1 + \frac{m_i}{m_2} T_i + \frac{m_i\, R}{m_2 C_{v0}} T_i$$

$$= \frac{1}{1.4} 300 + \frac{0.4}{1.4} 500 + \frac{0.4}{1.4} \frac{0.2968}{0.745} 500 = \mathbf{414.0\ K}$$

We need the pressure for the entropy

$$P_2 = m_2 R T_2/V = 1.4\, P_1 \times T_2/T_1 = 1.4 \times 200 \times 414/300 = 386.4\ \text{kPa}$$

$$m_1 = \frac{P_1 V_1}{RT_1} = \frac{200 \times 0.2}{0.2968 \times 300} = 0.4492\ \text{kg}; \quad m_2 = 1.4\, m_1 = 0.6289\ \text{kg}$$

The entropy generation, with entropy difference from Eq.6.16, becomes

$${}_1S_{2\,gen} = m_2 s_2 - m_1 s_1 - m_i s_i = m_2(s_2 - s_i) - m_1(s_1 - s_i)$$

$$= m_2 \left[C_{P0} \ln\left(\frac{T_2}{T_i}\right) - R \ln\left(\frac{P_2}{P_i}\right)\right] - m_1 \left[C_{P0} \ln\left(\frac{T_1}{T_i}\right) - R \ln\left(\frac{P_1}{P_i}\right)\right]$$

$$= 0.6289\left[\, 1.042 \ln\left(\frac{414}{500}\right) - 0.2968 \ln\left(\frac{386.4}{500}\right)\right]$$

$$- 0.4492 \left[1.042 \ln\left(\frac{300}{500}\right) - 0.2968 \ln\left(\frac{200}{500}\right)\right] = 0.0414\ \text{kJ/K}$$

$$\Phi_{destruction} = T_o\, {}_1S_{2\,gen} = 298.15 \times 0.0414\ \text{kJ} = \mathbf{12.34\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.78

A 10-kg iron disk brake on a car is initially at 10°C. Suddenly the brake pad hangs up, increasing the brake temperature by friction to 110°C while the car maintains constant speed. Find the change in exergy of the disk and the energy depletion of the car's gas tank due to this process alone. Assume that the engine has a thermal efficiency of 35%.

Solution:

All the friction work is turned into internal energy of the disk brake.

Energy eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2 \Rightarrow {}_1Q_2 = m_{Fe}C_{Fe}(T_2 - T_1)$

${}_1Q_2 = 10 \times 0.45 \times (110 - 10) = 450$ kJ

Neglect the work to the surroundings at P_0, so change in exergy is from Eq.8.27

$\Delta\phi = m(u_2 - u_1) - T_0 m(s_2 - s_1)$

Change in s for a solid, Eq.6.11

$$m(s_2 - s_1) = mC \ln(T_2/T_1) = 10 \times 0.45 \times \ln\left(\frac{383.15}{283.15}\right) = 1.361 \text{ kJ/K}$$

$\Delta\phi = 450 - 283.15 \times 1.361 =$ **64.63 kJ**

$W_{engine} = \eta_{th} Q_{gas} = {}_1Q_2 =$ Friction work

$Q_{gas} = {}_1Q_2/\eta_{th} = 450/0.35 =$ **1285.7 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.79

Water as saturated liquid at 200 kPa goes through a constant pressure heat exchanger as shown in Fig. P8.79. The heat input is supplied from a reversible heat pump extracting heat from the surroundings at 17°C. The water flow rate is 2 kg/min and the whole process is reversible, that is, there is no overall net entropy change. If the heat pump receives 40 kW of work find the water exit state and the increase in exergy of the water.

C.V. Heat exchanger + heat pump.

$\dot{m}_1 = \dot{m}_2 = 2$ kg/min, $\quad \dot{m}_1 h_1 + \dot{Q}_0 + \dot{W}_{in} = \dot{m}_1 h_2, \quad \dot{m}_1 s_1 + \dot{Q}_0/T_0 = \dot{m}_1 s_2$

Substitute $\dot{Q}_0$ into energy equation and divide by $\dot{m}_1$

$$h_1 - T_0 s_1 + w_{in} = h_2 - T_0 s_2$$

LHS = 504.7 - 290.15 × 1.5301 + 40×60/2 = 1260.7 kJ/kg

State 2: P_2 , $\quad h_2 - T_0 s_2 = 1260.7$ kJ/kg

At sat. vap. $h_g - T_0 s_g = 638.8$ so state 2 is superheated vapor at 200 kPa.

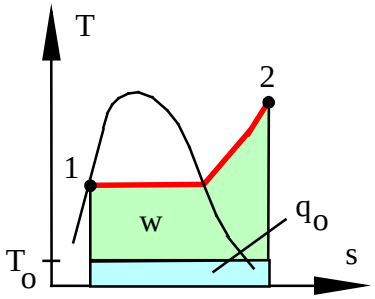
At 600°C: $\quad h_2 - T_0 s_2 = 3703.96 - 290.15 \times 8.7769 = 1157.34$ kJ/kg

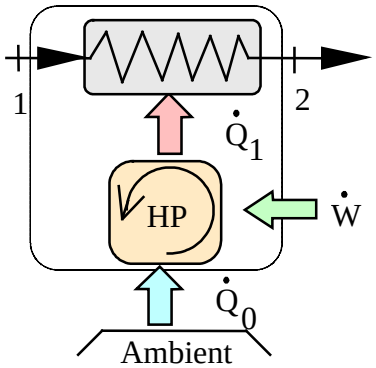
At 700°C: $\quad h_2 - T_0 s_2 = 3927.66 - 290.15 \times 9.0194 = 1310.68$ kJ/kg

Linear interpolation $\Rightarrow$ **T_2 = 667°C**

$\Delta\psi = (h_2 - T_0 s_2) - (h_1 - T_0 s_1) = w_{in} =$ **1200 kJ/kg**

$= 1260.7 - 504.7 + 290.15 \times 1.5301 \approx$ **1200 kJ/kg**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.80

Ammonia, 2 kg, at 400 kPa, 40°C is in a piston/cylinder together with an unknown mass of saturated liquid ammonia at 400 kPa. The piston is loaded so it keeps constant pressure and the two masses are allowed to mix to a final uniform state of saturated vapor without external heat transfer. Find the total exergy destruction in the process.

C.V. All the ammonia.

Continuity Eq.: $m_2 - m_A - m_B = 0$

Energy Eq.: $m_2u_2 - m_Au_A - m_Bu_B = Q - W$

Entropy Eq.: $m_2s_2 - m_As_A - m_Bs_B = \int dQ/T + {}_1S_{2\ gen}$

Process: $Q = 0,\ P = C$ so $W = P(V_2 - V_A - V_B)$

State A: $h_A = 1543.6$ kJ/kg, $s_A = 5.7111$ kJ/kg-K, $m_A = 2$ kg

State B: $h_B = 171.65$ kJ/kg, $s_B = 0.6793$ kJ/kg-K, $m_B = ?$ kg

State 2: $h_2 = 1440.2$ kJ/kg, $s_2 = 5.3559$ kJ/kg-K, $m_2 = m_A + m_B$

Insert the process equation into the energy equation

$$m_2h_2 - m_Ah_A - m_Bh_B = 0$$

Now solve the energy equation for the unknown mass m_B

$$m_B = m_A \frac{h_2 - h_A}{h_B - h_2} = 2 \text{ kg} \frac{1440.2 - 1543.6}{171.65 - 1440.2} = 0.163 \text{ kg}$$

Solve for entropy generation

$$\begin{aligned} {}_1S_{2\ gen} &= m_2s_2 - m_As_A - m_Bs_B \\ &= 2.163 \times 5.3559 - 2 \times 5.7111 - 0.163 \times 0.6793 \\ &= 0.051886 \text{ kJ/K} \end{aligned}$$

Exergy destruction

$$\psi_{destruction} = T_o\, S_{gen} = 298.15 \times 0.051886 = \mathbf{15.47\ kJ}$$

Exergy Balance Equation

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.81

Apply the exergy equation to solve Problem 8.18
A refrigerator should remove 1.5 kW from the cold space at -10°C while it rejects heat to the kitchen at 25°C. Find the reversible work.

The exergy balance equation is Eq.8.38

$$\frac{d\Phi}{dt} = \left(1 - \frac{T_o}{T}\right) \dot{Q}_{cv} - \dot{W}_{cv} + P_o \frac{dV}{dt} + \dot{m}_i \psi_i - \dot{m}_e \psi_e - T_o \dot{S}_{gen}$$

$$0 = (1 - \frac{T_o}{T_L}) \dot{Q}_L - (1 - \frac{T_o}{T_H}) \dot{Q}_H - \dot{W}_{cv} + 0 + 0 - 0 - 0$$

The two d/dt terms are zero due to steady state, no flow and reversible give zero for the last three terms so we get the equation we can solve for the work

$$\dot{W}_{cv} = (1 - \frac{T_o}{T_L}) \dot{Q}_L - (1 - \frac{T_o}{T_H}) \dot{Q}_H$$

To solve we need the heat transfer $\dot{Q}_H$ as we do have $\dot{Q}_L$ = 1.5 kW. We need to use the entropy equation to get

$$\dot{Q}_H = (T_H/T_L)\, \dot{Q}_L = \frac{298.15}{263.15} 1.5 \text{ kW} = 1.6995 \text{ kW}$$

$$\dot{W}_{cv} = (1 - \frac{T_o}{T_L}) \dot{Q}_L - (1 - \frac{T_o}{T_H}) \dot{Q}_H = \dot{Q}_L - \dot{Q}_H + \frac{T_o}{T_H} \dot{Q}_H - \frac{T_o}{T_L} \dot{Q}_L$$

$$= \dot{Q}_L - \dot{Q}_H = 1.5 - 1.6995 = -0.1995 \text{ kW} = \mathbf{-0.2\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.82

Apply the exergy equation to solve Problem 8.35 with $T_o = 20^oC$.

A 20^oC room is heated with a 2000 W electric baseboard heater. What is the rate of irreversibility?

The exergy balance equation is Eq.8.38

$$\frac{d\Phi}{dt} = \left(1 - \frac{T_o}{T}\right) \dot{Q}_{cv} - \dot{W}_{cv} + P_o \frac{dV}{dt} + \dot{m}_i \psi_i - \dot{m}_e \psi_e - T_o \dot{S}_{gen}$$

For the heater we have steady state (d/dt terms are zero), one $\dot{Q}_{cv}$ out at T_o, electrical work in and no flow terms leaving us with

$$0 = \left(1 - \frac{T_o}{T_o}\right) \times \dot{Q}_{cv} + \dot{W}_{electrical} - T_o \dot{S}_{gen}$$

$$\dot{I} = T_o \dot{S}_{gen} = \dot{W}_{electrical} = \mathbf{2000\ W}$$

This assumes that $T_o = 20^oC$.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.83

Estimate some reasonable temperatures to use and find all the fluxes of exergy in the refrigerator given in Example 5.2

We will assume the following temperatures:

Ambient: $T = 20^{o}C$ usually it is the kitchen air.

Low T: $T = 5^{o}C$ (refrigerator) $T = -10^{o}C$ (freezer)

$$\dot{\Phi}_W = \dot{W} = \mathbf{150\ W}$$

$$\dot{\Phi}_H = (1 - \frac{T_o}{T_H})\, \dot{Q}_H = (1 - \frac{T_{amb}}{T_{amb}})\, \dot{Q}_H = \mathbf{0}$$

$$\dot{\Phi}_L = (1 - \frac{T_o}{T_L})\, \dot{Q}_L = (1 - \frac{293}{278})\, 250 = \mathbf{-13.5\ W}$$

I.e. the flux goes into the cold space! Why? As you cool it $T < T_o$ and you increase its exergy, it is further away from the ambient.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.84

Find the specific flow exergy in and out of the steam turbine in Example 7.1 assuming an ambient at 293 K. Use the exergy balance equation to find the reversible specific work. Does this calculation of specific work depend on T_o?

Solution:

The specific flow exergy is from Eq. 8.22

$$\psi_i = h_i + \frac{1}{2}\mathbf{V}_i^2 - T_o s_i - (h_o - T_o s_o)$$

Reference state: $h_o = 83.94$ kJ/kg, $s_o = 0.2966$ kJ/kg K,

$$h_o - T_o s_o = -2.9638 \text{ kJ/kg}$$

The properties are listed in Example 7.1 so the specific flow exergies are

$$\psi_i = 3051.2 + 1.25 - 293 \times 7.1228 - (-2.9638) = \mathbf{968.43\ kJ/kg}$$

$$\psi_e = 2655.0 + 20 - 293 \times 7.1228 - (-2.9638) = \mathbf{590.98\ kJ/kg}$$

The reversible work is from Eq.8.29, with q = 0 and steady state, so

$$w = \psi_i - \psi_e = 968.43 - 590.98 = \mathbf{377.45\ kJ/kg}$$

The offset T_o terms drop out as we take the difference and also ($s_i = s_e$)

$$\psi_i - \psi_e = h_i - h_e - T_o(s_i - s_e) = h_i - h_e$$

Notice since the turbine is reversible we get the same as in Example 7.1

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.85

Apply the exergy equation to solve Problem 8.36.
A refrigerator removes 1.5 kW from the cold space at -10°C using 750 W of power input while it rejects heat to the kitchen at 25°C. Find the rate of irreversibility.

The exergy balance equation is Eq.8.38

$$\frac{d\Phi}{dt} = \left(1 - \frac{T_o}{T}\right) \dot{Q}_{cv} - \dot{W}_{cv} + P_o \frac{dV}{dt} + \dot{m}_i \psi_i - \dot{m}_e \psi_e - T_o \dot{S}_{gen}$$

$$0 = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L - \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H - \dot{W}_{cv} + 0 + 0 - 0 - T_o \dot{S}_{gen}$$

The two d/dt terms are zero due to steady state and no flow. Now solve for the irreversibility, notice the $\dot{Q}_H$ term drops out since $T_H = T_o$.

$$\dot{I} = T_o \dot{S}_{gen} = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L - \dot{W}_{cv}$$

$$= \left(1 - \frac{298.15}{263.15}\right) 1.5 \text{ kW} - (-0.75) \text{ kW}$$

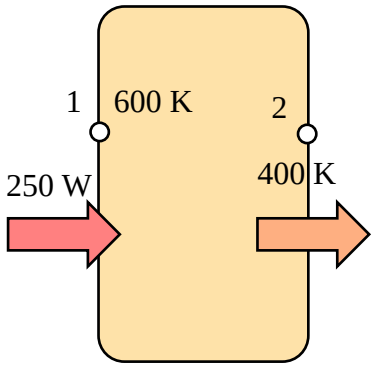
$$= -0.2 \text{ kW} + 0.75 \text{ kW} = \mathbf{0.55\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.86

Evaluate the steady state exergy fluxes due to a heat transfer of 50 W through a wall with 600 K on one side and 400 K on the other side. What is the exergy destruction in the wall.

Solution:



Exergy flux due to a $\dot{Q}$ term Eq.8.36:

$$\dot{\Phi}_Q = (1 - \frac{T_o}{T})\,\dot{Q}$$

$$\dot{\Phi}_1 = (1 - \frac{T_o}{T_1})\,\dot{Q} = (1 - \frac{298}{600})\,50 = 25.2 \text{ W}$$

$$\dot{\Phi}_2 = (1 - \frac{T_o}{T_2})\,\dot{Q} = (1 - \frac{298}{400})\,50 = 12.75 \text{ W}$$

Steady state state so no storage and Eq.8.38 is

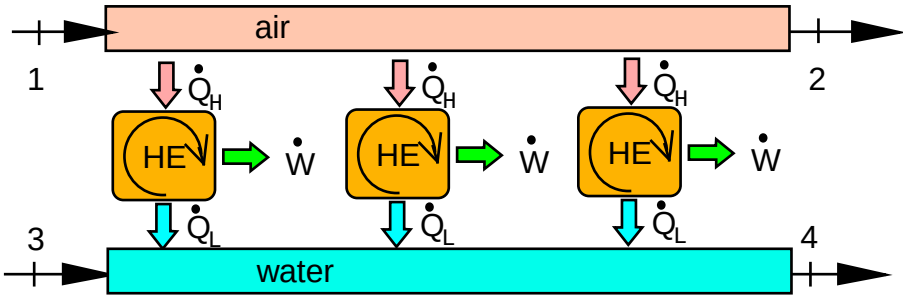
$$0 = \dot{\Phi}_1 - \dot{\Phi}_2 - \dot{\Phi}_{destr.}$$

$$\dot{\Phi}_{destr.} = \dot{\Phi}_1 - \dot{\Phi}_2 = 25.2 - 12.75 = \mathbf{12.45\ W}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.87

A counterflowing heat exchanger cools air at 600 K, 400 kPa to 320 K using a supply of water at 20°C, 200 kPa. The water flow rate is 0.1 kg/s and the air flow rate is 1 kg/s. Assume this can be done in a reversible process by the use of heat engines and neglect kinetic energy changes. Find the water exit temperature and the power out of the heat engine(s).



C.V. Total

Energy eq.: $\dot{m}_a h_1 + \dot{m}_{H_2O} h_3 = \dot{m}_a h_2 + \dot{m}_{H_2O} h_4 + \dot{W}$

Entropy Eq,: $\dot{m}_a s_1 + \dot{m}_{H_2O} s_3 = \dot{m}_a s_2 + \dot{m}_{H_2O} s_4$ $\quad (s_{gen} = 0)$

Table A.7: $h_1 = 607.316$ kJ/kg, $\quad s^\circ_{T1} = 7.57638$ kJ/kg K

Table A.7: $h_2 = 320.576$ kJ/kg, $\quad s^\circ_{T2} = 6.93413$ kJ/kg K,

Table B.1.1: $\quad h_3 = 83.96$ kJ/kg, $\quad s_3 = 0.2966$ kJ/kg K

From the entropy equation we first find state 4

$$s_4 = (\dot{m}_a/\dot{m}_{H_2O})(s_1 - s_2) + s_3 = (1/0.1)(7.57638 - 6.93413) + 0.2966 = 6.7191$$

4: $P_4 = P_3$, $s_4 \Rightarrow$ Table B.1.2: $\quad x_4 = (6.7191\text{-}1.530)/5.597 = 0.9271$,

$h_4 = 504.68 + 0.9271 \times 2201.96 = 2546.1$ kJ/kg, $\quad T_4 =$ **120.20°C**

From the energy equation

$$\dot{W} = \dot{m}_a(h_1 - h_2) + \dot{m}_{H_2O}(h_3 - h_4)$$

$$= 1(607.32 - 320.58) + 0.1(83.96 - 2546.1) = \mathbf{40.53\ kW}$$

The work could be found from the exergy balance equation (requires state 4) as

$$\dot{W} = \dot{m}_a(\psi_1 - \psi_2) + \dot{m}_{H_2O}(\psi_3 - \psi_4)$$

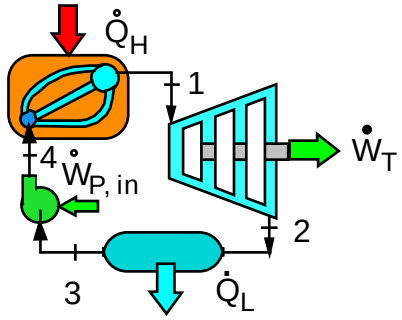
Since the entropies (including $\dot{m}$'s) balance out it is the same as the energy Eq.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.88

Consider the condenser in Problem 7.48. Find the specific energy and exergy that are given out, assuming an ambient at 20°C. Find also the specific exergy destruction in the process.

Solution:



Condenser from state 2 to state 3

$P_2 = P_3 = 20$ kPa

$T_3 = 40$ °C

State 1: (P, T) Table B.1.3

$h_1 = 3809.1$ kJ/kg, $s_1 = 6.7993$ kJ/kg K

C.V. Turbine.

Entropy Eq.7.8: $s_2 = s_1 = 6.7993$ kJ/kg K

Table B.1.2 $s_2 = 0.8319 + x_2 \times 7.0766$ => $x_2 = 0.8433$

$h_2 = 251.4 + 0.8433 \times 2358.33 = 2240.1$ kJ/kg

State 3: (P, T) Compressed liquid, take sat. liq. Table B.1.1

$h_3 = 167.54$ kJ/kg, $s_3 = 0.5724$ kJ/kg K

C.V. Condenser

Energy Eq.: $q_L = h_2 - h_3 = 2240.1 - 167.54 =$ **2072.56 kJ/kg**

Exergy Eq.: $\Delta\psi = \psi_2 - \psi_3 = h_2 - h_3 - T_o(s_2 - s_3)$

$= 2072.56 - 293.15(6.7993 - 0.5724)$

$=$ **247.1 kJ/kg** going out

Since all the exergy that goes out ends up at the ambient where it has zero exergy, the destruction equals the outgoing exergy.

$\psi_{destr} = \Delta\psi =$ **247.1 kJ/kg**

Notice the condenser gives out a large amount of energy but little exergy.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

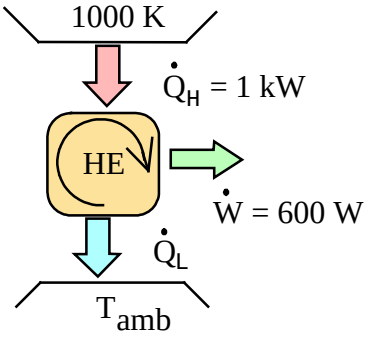
8.89

Apply the exergy equation to find the exergy destruction for Problem 8.54

$$\text{Exergy flux in: } \dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right)\dot{Q}_H = \left(1 - \frac{298.15}{1000}\right) 1 \text{ kW} = 0.702 \text{ kW}$$

$$\text{Exergy flux out: } \dot{\Phi}_L = \left(1 - \frac{T_o}{T_L}\right)\dot{Q}_L = 0 \qquad (T_L = T_o)$$

The other exergy flux out is the power $\dot{\Phi}_{out} = \dot{W} = 0.6$ kW



The exergy balance equation Eq.8.38 for the HE becomes (steady state)

$$0 = \dot{\Phi}_H - \dot{\Phi}_L - \dot{W} - \dot{\Phi}_{destruction}$$

$$\dot{\Phi}_{destruction} = \dot{\Phi}_H - \dot{\Phi}_L - \dot{W} = 702 \text{ W} - 0 - 600 \text{ W} = \mathbf{102\ W}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

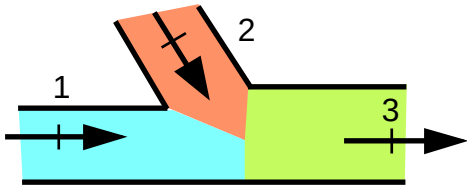
8.90

A flow of 1 kg/s of air at 300 K is mixed with a flow of 2 kg/s air at 1500 K in an insulated pipe junction at a pressure of 100 kPa. Find the exit temperature and the exergy destruction.

Solution:

Continuity Eq.4.9:

$$\dot{m}_1 + \dot{m}_2 = \dot{m}_3 = 1 + 2 = 3 \text{ kg/s}$$



Energy Eq.4.10:

$$\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3$$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{S}_{gen} = \dot{m}_3 s_3$

Due to high T at state 2 use A.7 and Eq.6.19 for s change.

$$h_3 = (\dot{m}_1/\dot{m}_3)h_1 + (\dot{m}_2/\dot{m}_3)h_2 = \frac{1}{3} \times 300.47 + \frac{2}{3} \times 1635.8 = 1190.69 \text{ kJ/kg}$$

From A.7.1: $T_3 =$ **1125.4 K** $\qquad s_{T_3} = 8.27073$ kJ/kg K

$$\dot{S}_{gen} = 2(8.27073 - 8.61208) + 1(8.27073 - 6.86926)$$

$$= 0.71877 \text{ kW/K}$$

$$\dot{\Phi}_{destruction} = T_o \dot{S}_{gen} = 298.15 \times 0.71877 = \textbf{214.3 kW}$$

The pressure correction part of the entropy terms cancel out as all three states have the same pressure.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.91

The condenser in a power plant cools 10 kg/s water at 10 kPa, quality 90% so it comes out as saturated liquid at 10 kPa. The cooling is done by ocean-water coming in at ambient 15°C and returned to the ocean at 20°C. Find the transfer out of the water and the transfer into the ocean-water of both energy and exergy (4 terms).

Solution:
C.V. Water line. No work but heat transfer out.

Energy Eq.: $\dot{Q}_{out} = \dot{m}\,(h_1 - h_2) = 10(2345.35 - 191.81) =$ **21 535 kW**

C.V. Ocean water line. No work but heat transfer in equals water heattransfer out

Energy Eq.: $q = h_4 - h_3 = 83.94 - 62.98 = 20.96$ kJ/kg

$$\dot{m}_{ocean} = \dot{Q}_{out}/q = 21\,535 / 20.96 = 1027.4 \text{ kg/s}$$

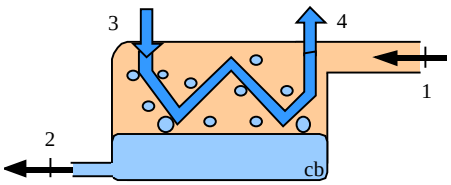
Exergy out of the water follows from a flow term in Eq.8.38

$$\dot{\Phi}_{out} = \dot{m}(\psi_1 - \psi_2) = \dot{m}\,[\,h_1 - h_2 - T_0\,(s_1 - s_2)\,]$$
$$= 10\,[\,2345.35 - 191.81 - 288.15(7.4001 - 0.6492)]$$
$$= \mathbf{2082.3\ kW}$$

Exergy into the ocean water

$$\dot{\Phi}_{ocean} = \dot{m}_{ocean}(\psi_4 - \psi_3) = \dot{m}_{ocean}\,[\,h_4 - h_3 - T_0(s_4 - s_3)]$$
$$= 1027.4\,[\,20.96 - 288.15(0.2966 - 0.2245)]$$
$$= \mathbf{189.4\ kW}$$

Notice there is a large amount of energy exchanged but very little exergy.



Often the cooling media flows inside a long pipe carrying the energy away.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.92

Consider the car engine in Example 5.1 and assume the fuel energy is delivered at a constant 1500 K. The 70% of the energy that is lost is 40% exhaust flow at 900 K and the remainder 30% heat transfer to the walls at 450 K goes on to the coolant fluid at 370 K, finally ending up in atmospheric air at ambient 20°C. Find all the energy and exergy flows for this heat engine. Find also the exergy destruction and where that is done.

From the example in the text we get: $\dot{Q}_L = 0.7\ \dot{Q}_H = 233$ kW

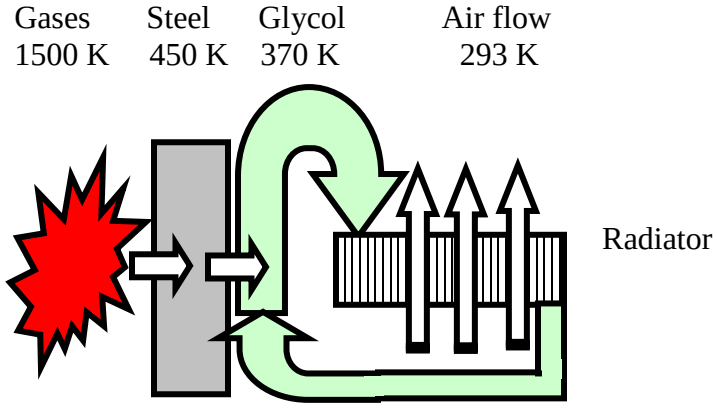
This is separated into two fluxes:

$\dot{Q}_{L1} = 0.4\ \dot{Q}_H = 133$ kW @900 K

$\dot{Q}_{L2} = 0.3\ \dot{Q}_H = 100$ kW @450 K

$= \dot{Q}_{L3} = 100$ kW @370 K

$= \dot{Q}_{L4} = 100$ kW @293 K



Assume all the fuel energy is delivered at 1500 K then that has an exergy of

$$\dot{\Phi}_{QH} = (1 - \frac{T_o}{T_H})\ \dot{Q}_H = (1 - \frac{293}{1500})\ 333 = 267.9 \text{ kW}$$

Work is exergy

$$\dot{\Phi}_W = \dot{W} = 100 \text{ kW}$$

The exhaust flow exergy becomes

$$\dot{\Phi}_{QL1} = (1 - \frac{T_o}{T_{L1}})\ \dot{Q}_H = (1 - \frac{293}{900})\ 133 = 89.7 \text{ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

The heat transfer through the coolant keeps dropping in temperature and are

$$\dot{\Phi}_{QL2} = (1 - \frac{T_o}{T_{L2}})\, \dot{Q}_{QL2} = (1 - \frac{293}{450})\, 100 = 34.9 \text{ kW}$$

$$\dot{\Phi}_{QL3} = (1 - \frac{T_o}{T_{L3}})\, \dot{Q}_{QL3} = (1 - \frac{293}{370})\, 100 = 20.8 \text{ kW}$$

$$\dot{\Phi}_{QL4} = (1 - \frac{T_o}{T_{L4}})\, \dot{Q}_{QL4} = (1 - \frac{293}{293})\, 100 = 0 \text{ kW}$$

The destruction terms are the drops in exergy fluxes. For the inside of the cylinder

$$\dot{\Phi}_{\text{Destruction inside}} = \dot{\Phi}_{QH} - \dot{W} - \dot{\Phi}_{QL1} - \dot{\Phi}_{QL2} = 43.3 \text{ kW}$$

Outside the cylinder, the wall that separates the gas from the coolant gives

$$\dot{\Phi}_{\text{Destruction wall}} = \dot{\Phi}_{QL2} - \dot{\Phi}_{QL3} = 14.1 \text{ kW}$$

The wall in the radiator separating the coolant from the air gives

$$\dot{\Phi}_{\text{Destruction radiator}} = \dot{\Phi}_{QL3} - \dot{\Phi}_{QL4} = 20.8 \text{ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.93

A piston/cylinder has forces on the piston so it keeps constant pressure. It contains 2 kg of ammonia at 1 MPa, 40°C and is now heated to 100°C by a reversible heat engine that receives heat from a 200°C source. Find the work out of the heat engine using the exergy balance equation.

Solution:

To evaluate it we need the change in exergy Eq.8.28

$$\Phi_2 - \Phi_1 = m_{am}(u_2 - u_1) + P_o(V_2 - V_1) - m_{am}T_o(s_2 - s_1)$$

The work ($W = W_{H.E.} + {}_1W_{2,pist}$) is from the integrated exergy Eq.8.38

for a reversible process with no flow terms and use of Eq.8.28

$$W = P_o(V_2 - V_1) + (1 - \frac{T_o}{T_H}){}_1Q_2 - (\Phi_2 - \Phi_1) - 0$$

$$= (1 - \frac{T_o}{T_H}){}_1Q_2 - m_{am}(u_2 - u_1) + m_{am}T_o(s_2 - s_1)$$

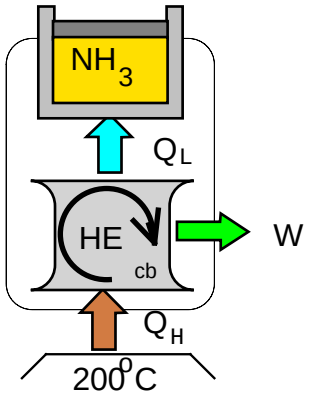
Now we must evaluate the three terms on the RHS and the work ${}_1W_{2,pist}$.

State 1: $u_1 = 1369.8$ kJ/kg, $v_1 = 0.13868$ m^3/kg, $s_1 = 5.1778$ kJ/kg K

State 2: $u_2 = 1490.5$ kJ/kg, $v_2 = 0.17389$ m^3/kg, $s_2 = 5.6342$ kJ/kg K

$${}_1W_{2,pist} = m_{am}P(v_2 - v_1) = 2 \times 1000\ (0.17389 - 0.13868) = 70.42 \text{ kJ}$$

C.V. Heat engine and ammonia (otherwise we involve another Q)



Entropy: $m_{am}(s_2 - s_1) = {}_1Q_2/T_H + 0$

$$\Rightarrow {}_1Q_2 = T_H\, m_{am}(s_2 - s_1)$$

$$= 473.15 \times 2\ (5.6342 - 5.1778)$$

$$= 431.89 \text{ kJ}$$

Substitute this heat transfer into the work term

$$W = (1 - \frac{298.15}{473.15})\ 431.89 - 2(1490.5 - 1369.8) + 2 \times 298.15(5.6342 - 5.1778)$$

$$= 159.74 - 241.4 + 272.15 = 190.49 \text{ kJ}$$

$$W_{H.E.} = W - {}_1W_{2,pist} = 190.49 - 70.42 = \mathbf{120.0\ kJ}$$

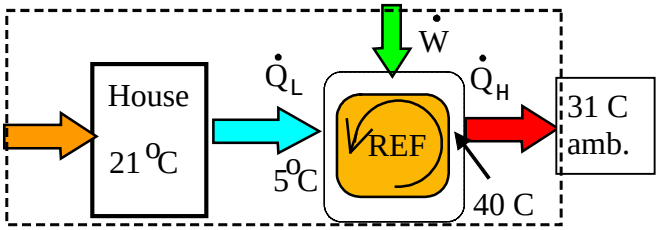
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.94

An air-conditioner on a hot summer day removes 8 kW of energy from a house at 21°C and pushes energy to the outside which is at at 31°C. The house has 15 000 kg mass with an average specific heat of 0.95 kJ/kgK. In order to do this the cold side of the air-conditioner is at 5°C and the hot side is at 40°C. The air-conditioner (refrigerator) has a COP that is 60% of a corresponding Carnot refrigerator. Find the actual air-conditioner COP, the power required to run the air-conditioner, the rate of exergy destruction **inside** the air conditioner and the total rate of exergy destruction due to the air-conditioner and house.

Any heat transfer must go from a higher to a lower T domain.

Q leak from atm. 31 C



A steady state refrigerator definition of COP

$$\text{COP} = \beta_{REF} = \dot{Q}_L / \dot{W} = \dot{Q}_L / (\dot{Q}_H - \dot{Q}_L) = 0.6\, \beta_{Carnot}$$

Carnot: $\beta_{Carnot} = \dfrac{T_L}{T_H - T_L} = \dfrac{5 + 273.15}{40 - 5} = 7.95$; $\beta_{REF} = 0.6 \times 7.95 = \mathbf{4.77}$

$$\Rightarrow \quad \dot{W} = \dot{Q}_L / \beta_{REF} = 8 \text{ kW} / 4.77 = \mathbf{1.68\ kW}$$

$$\dot{Q}_H = \dot{Q}_L + \dot{W} = 9.68 \text{ kW}$$

C.V. Refrigerator (A/C unit).

Energy Eq.: $\dot{E}_{CV} = 0 = \dot{Q}_L + \dot{W} - \dot{Q}_H$

Entropy Eq.: $\dot{S}_{CV} = 0 = \dfrac{\dot{Q}_L}{T_L} - \dfrac{\dot{Q}_H}{T_H} + \dot{S}_{gen\ a/c} \quad \Rightarrow$

$$\dot{\Phi}_{destr.} = T_o\, \dot{S}_{gen\ a/c} = 298.15 \left[\frac{9.68}{40 + 273.15} - \frac{8}{5 + 273.15} \right] = \mathbf{0.64\ kW}$$

CV. Total: house + A/C unit, $\dot{Q}_{Leak}$ and $\dot{Q}_H$ comes from and leaves to atm.

Energy Eq.: $\dot{E}_{CV} = 0 = \dot{Q}_{leak} + \dot{W} - \dot{Q}_H$

Entropy Eq.: $\dot{S}_{CV} = 0 = \dfrac{\dot{Q}_{leak}}{T_{atm}} - \dfrac{\dot{Q}_H}{T_{atm}} + \dot{S}_{gen\ tot} \quad \Rightarrow \dot{S}_{gen\ tot} = \dfrac{\dot{W}}{T_{atm}}$

$$\dot{\Phi}_{destr.} = T_o\, \dot{S}_{gen\ tot} = T_o \frac{\dot{W}}{T_{atm}} = 298.15 \text{ K} \frac{1.68 \text{ kW}}{304.15 \text{ K}} = \mathbf{1.65\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.95

If the air-conditioner in the previous problem is turned off how fast does the house heat up in K/sec?

Once the A/C unit is turned off we do not cool the house so heat leaks in from the atm. at a rate of 8 kW (that is what we had to remove to keep steady state).

Energy Eq.: $$\dot{E}_{CV} = \dot{Q}_{leak} = 8 \text{ kW} = m_{house} C_P \frac{dT}{dt}$$

$$\frac{dT}{dt} = \dot{Q}_{leak} / m_{house} C_P = \frac{8 \text{ kW}}{15\,000 \times 0.95 \text{ kJ/K}} = \mathbf{0.56 \times 10^{-3} \text{ K/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.96

A disk brake of 2 kg steel and 1 kg brake pads is at 20°C. The brakes are now stopping a car so they dissipate energy by friction and heats up to $T_2 = 200^oC$. Assume the brake pads have specific heat of 0.6 kJ/kg-K. After this process the disk and pads now slowly cools to the ambient $20^oC = T_3$. Find the exergy destruction in the braking process (1 to 2) and that in the cooling process (2 to 3).

Control volume around the disk brake assembly.
Energy equation

$$U_2 - U_1 = {}_1Q_2 - {}_1W_2 = -\,{}_1W_2 = m_{st}C_{st}\,(T_2 - T_1) + m_{pad}C_{pad}\,(T_2 - T_1)$$

$$= (2 \times 0.46 + 1 \times 0.6)\ \text{kJ/K} \times (200 - 20)\ \text{K} = 273.6\ \text{kJ}$$

Entropy equation

$$S_2 - S_1 = 0 + {}_1S_{2\ \text{gen}} = {}_1S_{2\ \text{gen}} = m_{st}C_{st}\ln(T_2/T_1) + m_{pad}C_{pad}\ln(T_2/T_1)$$

$$= (2 \times 0.46 + 1 \times 0.6)\ln\frac{473}{293} = 0.7277\ \text{kJ/K}$$

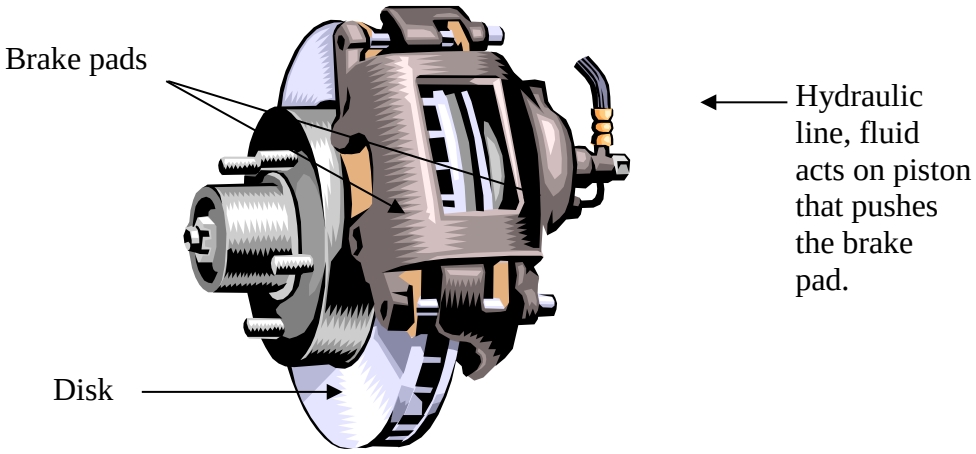
$${}_1\Phi_{2\ \text{destruction}} = T_o\ {}_1S_{2\ \text{gen}} = 298.15\ \text{K} \times 0.7277\ \text{kJ/K} = \mathbf{217\ kJ}$$

The cooling process 2 to 3, extend CV out to ambient T_o.

$$U_3 - U_2 = {}_2Q_3 = -\,273.6\ \text{kJ} \quad [\,= -\,(U_2 - U_1)\,]$$

$${}_2S_{3\ \text{gen}} = S_3 - S_2 - {}_2Q_3 / T_o = -\,0.7277 - \frac{-273.6}{293} = 0.2056\ \text{kJ/K}$$

$${}_2\Phi_{3\ \text{destruction}} = T_o\ {}_2S_{3\ \text{gen}} = 298.15\ \text{K} \times 0.2056\ \text{kJ/K} = \mathbf{61.3\ kJ}$$



Clip-art from Microsoft.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.97

A small house kept at 20°C inside loses 12 kW to the outside ambient at 0°C. A heat pump is used to help heat the house together with possible electrical heat. The heat pump is driven by a motor of 2.5 kW and it has a COP that is one quarter of a Carnot heat pump unit. Find the actual heat pump COP and the exergy destruction in the whole process.

CV. House

Energy: $0 = \dot{Q}_H + \dot{W}_{el.} - \dot{Q}_{Loss}$

Definition of COP: $\beta' = COP_{HP} = \dfrac{\dot{Q}_H}{\dot{W}} = \dfrac{1}{4}\dfrac{T_H}{T_H - T_L} = \dfrac{1}{4}\dfrac{293.15}{20 - 0} = \mathbf{3.664}$

$$\dot{Q}_H = COP_{HP}\, \dot{W}_{HP} = 3.664 \times 2.5 \text{ kW} = 9.16 \text{ kW}$$

$$\dot{W}_{el.} = \dot{Q}_{Loss} - \dot{Q}_H = 12 - 9.16 = 2.84 \text{ kW}$$

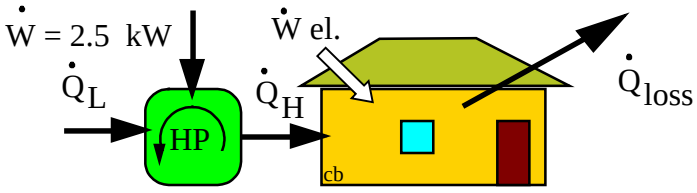
C.V. Total Energy: $0 = \dot{Q}_L + \dot{W}_{HP} + \dot{W}_{el.} - \dot{Q}_{Loss}$

$$\dot{Q}_{Loss} - \dot{Q}_L = \dot{W}_{HP} + \dot{W}_{el.} = 2.5 + 2.84 = 5.34 \text{ kW}$$

Entropy: $0 = \dot{Q}_L/T_L - \dot{Q}_{loss}/T_L + \dot{S}_{gen}$

$$\dot{\Phi}_{destr.} = T_o\, \dot{S}_{gen} = T_o\, (\dot{Q}_{loss} - \dot{Q}_L)\, /T_L = 273.15\, \frac{5.34}{273.15} = \mathbf{5.34\ kW}$$

Comment: We must use $T_o = 273.15$ K here as the $\dot{Q}_L$ and $\dot{Q}_{loss}$ were exchanged with the ambient. Otherwise the destruction becomes larger than the supplied work terms because the exergy exchanged with the ambient is non-zero



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.98

A farmer runs a heat pump using 2 kW of power input. It keeps a chicken hatchery at a constant 30°C while the room loses 10 kW to the colder outside ambient at 10°C. Find the COP of the heat pump, the rate of exergy destruction in the heat pump and its heat exchangers, and the rate of exergy destruction in the heat loss process.

C.V. Hatchery, steady state at 30°C for the hatchery

Energy Eq.: $0 = \dot{Q}_H - \dot{Q}_{Loss} \quad \Rightarrow \quad \dot{Q}_H = \dot{Q}_{Loss} = 10$ kW

$$COP = \dot{Q}_H / \dot{W} = 10\text{kW} / 2\text{ kW} = \mathbf{5}$$

C.V. Heat pump, steady state

Energy eq.: $0 = \dot{Q}_L + \dot{W} - \dot{Q}_H \quad \Rightarrow \quad \dot{Q}_L = \dot{Q}_H - \dot{W} = 8$ kW

Entropy Eq.: $0 = \dfrac{\dot{Q}_L}{T_L} - \dfrac{\dot{Q}_H}{T_H} + \dot{S}_{gen\ HP}$

$$\dot{S}_{gen\ HP} = \frac{\dot{Q}_H}{T_H} - \frac{\dot{Q}_L}{T_L} = \frac{10}{273 + 30} - \frac{8}{273 + 10} = 0.00473 \text{ kW/K}$$

$$\dot{\Phi}_{destr.\ HP} = T_o\, \dot{S}_{gen\ HP} = 283.15 \text{ K} \times 0.00473 \text{ kW/K} = \mathbf{1.34\ kW}$$

C.V. From hatchery at 30°C to the ambient 10°C. This is typically the walls and the outer thin boundary layer of air. Through this goes $\dot{Q}_{Loss}$.

Entropy Eq.: $0 = \dfrac{\dot{Q}_{Loss}}{T_H} - \dfrac{\dot{Q}_{Loss}}{T_{amb}} + \dot{S}_{gen\ walls}$

$$\dot{S}_{gen\ walls} = \frac{\dot{Q}_{Loss}}{T_{amb}} - \frac{\dot{Q}_{Loss}}{T_H} = \frac{10}{283} - \frac{10}{303} = 0.00233 \text{ kW/K}$$

$$\dot{\Phi}_{destr.\ walls} = T_o\, \dot{S}_{gen\ HP} = 283.15 \text{ K} \times 0.00233 \text{ kW/K} = \mathbf{0.66\ kW}$$

Comment: Notice the two exergy destruction terms exactly equals work input. It was necessary to use T_o as ambient T otherwise the flux of exergy associated with the heat transfers $\dot{Q}_L$ and $\dot{Q}_{Loss}$ would be non-zero and a storage effect present.

Device Second-Law Efficiency

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.99

A heat engine receives 1 kW heat transfer at 1000 K and gives out 400 W as work with the rest as heat transfer to the ambient. Find its first and second law efficiencies.

First law efficiency is based on the energies

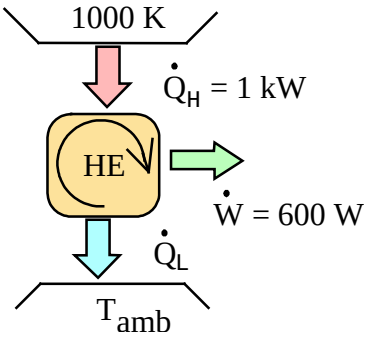
$$\eta_I = \dot{W}/\dot{Q}_H = \frac{0.4}{1} = \mathbf{0.4}$$

The second law efficiency is based on work out versus exergy in

Exergy flux in: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right)\dot{Q}_H = \left(1 - \frac{298.15}{1000}\right) 1 \text{ kW} = 0.702 \text{ kW}$

$$\eta_{II} = \frac{\dot{W}}{\dot{\Phi}_H} = \frac{0.4}{0.702} = \mathbf{0.57}$$

Notice the exergy flux in is equal to the Carnot heat engine power output given 1 kW at 1000 K and rejecting energy to the ambient.

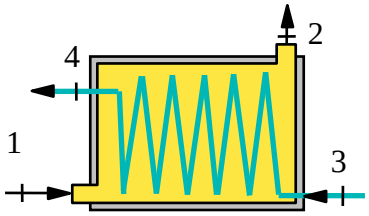


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.100

A heat exchanger increases the exergy of 3 kg/s water by 1650 kJ/kg using 10 kg/s air coming in at 1400 K and leaving with 600 kJ/kg less exergy. What are the irreversibility and the second law efficiency?

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for air and water each. The two flows exchange energy with no heat transfer to/from the outside.



The irreversibility is the destruction of exergy so

$$\dot{I} = \dot{\Phi}_{destruction} = \dot{\Phi}_{in} - \dot{\Phi}_{out} = 10 \times 600 - 3 \times 1650 = \mathbf{1050\ kW}$$

The second law efficiency, Eq.8.32

$$\eta_{II} = \dot{\Phi}_{out} / \dot{\Phi}_{in} = \frac{3 \times 1650}{10 \times 600} = \mathbf{0.825}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

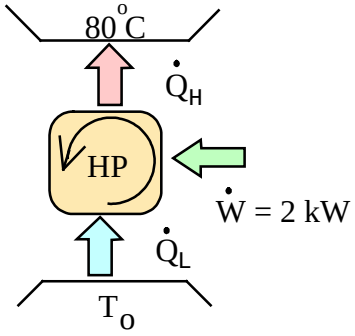
8.101

Find the second law efficiency of the heat pump in problem 8.57.

The second law efficiency is a ratio of exergies namely what we want out divided by what we have to put in. Exergy from first term on RHS Eq. 8.38

$$\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H; \qquad \dot{Q}_H = \beta\, \dot{W} = 2 \times 2 \text{ kW} = 4 \text{ kW}$$

$$\eta_{II} = \frac{\dot{\Phi}_H}{\dot{W}} = \left(1 - \frac{T_o}{T_H}\right) \frac{\dot{Q}_H}{\dot{W}} = \left(1 - \frac{298.15}{353.15}\right) \frac{4}{2} = \mathbf{0.31}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.102

A steam turbine inlet is at 1200 kPa, 500°C. The actual exit is at 300 kPa with an actual work of 407 kJ/kg. What is its second law efficiency?

The second law efficiency is the actual work out measured relative to the reversible work out, Eq. 8.29.

Steam turbine $T_o = 25°C = 298.15$ K

Inlet state: Table B.1.3 $h_i = 3476.28$ kJ/kg; $s_i = 7.6758$ kJ/kg K

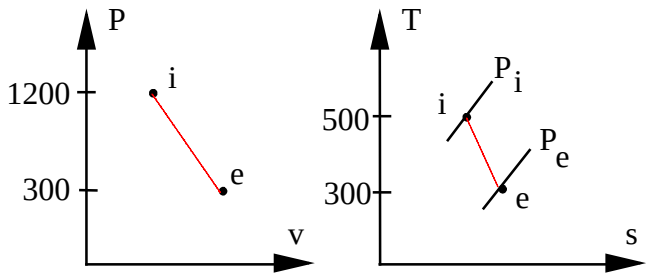
Actual turbine energy Eq.: $h_e = h_i - w_{ac} = 3476.28 - 407 = 3069.28$ kJ/kg

Actual exit state: Table B.1.3 $T_e = 300°C$; $s_e = 7.7022$ kJ/kg K

From Eq.8.29 for steady state and adiabatic process,

$$w^{rev} = (h_i - T_o s_i) - (h_e - T_o s_e) = (h_i - h_e) + T_o(s_e - s_i)$$
$$= (3476.28 - 3069.28) + 298.15(7.7022 - 7.6758)$$
$$= 407 + 7.87 = 414.9 \text{ kJ/kg}$$

$$\eta_{II} = w_{ac}/w^{rev} = 407 / 414.9 = \mathbf{0.98}$$



8.103

Find the second law efficiency for the compressor in problem 8.21.
An air compressor takes air in at the state of the surroundings 100 kPa, 300 K. The air exits at 400 kPa, 200°C using 100 kW of power. Determine the minimum compressor work input.

C.V. Compressor, Steady flow, minimum work in is reversible work.

Energy Eq.: $0 = h_1 - h_2 - w_c$ =>

$$-w_c = h_2 - h_1 = 475.8 - 300.47 = 175.33 \text{ kJ/kg}$$

$\psi_1 = 0$ at ambient conditions

Get the properties from the air table A.7.1 and correct standard entropy for the pressure

$$s_0 - s_2 = s^\circ_{T_0} - s^\circ_{T_2} - R \ln(P_0/P_2)$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$= 6.86926 - 7.3303 - 0.287 \ln(100/400) = -0.06317 \text{ kJ/kg K}$$

$$\psi_2 = h_2 - h_0 + T_0(s_0 - s_2) = 475.79 - 300.473 + 300\ (-0.06317)$$

$$= 156.365 \text{ kJ/kg}$$

$$-w^{REV} = (\psi_2 - \psi_1) = (156.365 - 0) \text{ kJ/kg} = 156.365 \text{ kJ/kg}$$

2^{nd} law efficiency: $\eta_{II} = \dfrac{w_{rev}}{w_{ac}} = \dfrac{-156.365}{-175.33} = \mathbf{0.892}$ $\left(= \dfrac{w_{ac} + i}{w_{ac}} \right)$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.104

Find the isentropic efficiency and the second law efficiency for the compressor in Problem 8.26.

A compressor in a refrigerator receives R-410A at 150 kPa, -40°C and it brings it up to 600 kPa, using an actual specific shaft work of 58.65 kJ/kg in an adiabatic compression. Find the specific reversible work.

C.V. Compressor. Assume adiabatic and neglect kinetic energies.

Energy Eq.: $0 = h_1 - h_2 - w$

Entropy Eq.7.8: $s_2 = s_1 + s_{gen}$

State 1: B.4.2 $h_1 = 263.99$ kJ/kg, $s_1 = 1.1489$ kJ/kg K

$h_{2,AC} = h_1 - w = 263.99 + 58.65 = 322.64$ kJ/kg

State 2ac: B.4.2 P, h_2 => $s_2 = 1.2152$ kJ/kg K

State 2s: B.4.2 (P, $s = s_1$) $h_{2,s} = 302.67$ kJ/kg

We have two different compressors:

IDEAL:	ACTUAL:
$-w_{c,s} = h_{2,s} - h_1 = 38.68$ kJ/kg	$-w_{C,AC} = h_{2,AC} - h_1 = 58.65$ kJ/kg

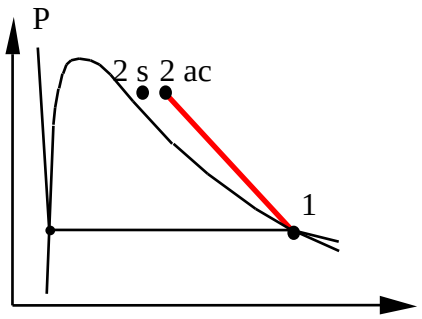
Definition Eq.7.27: $\eta_c = w_{c,s}/w_{c,AC} = \mathbf{0.659}$

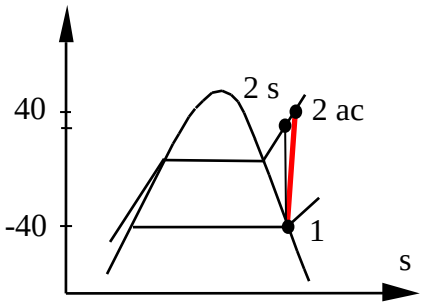
Rev. work Eq.8.29: $w_{rev} = \psi_1 - \psi_{2,AC} = h_1 - h_{2,AC} - T_0(s_1 - s_{2,AC})$

$= -58.65 - 298.15\,(1.1489 - 1.2152)$

$= -58.65 + 19.767 = -38.9$ kJ/kg

2nd law efficiency: $\eta_{II} = \dfrac{w_{rev}}{w_{ac}} = \dfrac{-38.9}{-58.65} = \mathbf{0.663}$ $\left(= \dfrac{w_{ac} + i}{w_{ac}} \right)$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.105

A steam turbine has inlet at 4 MPa, 500°C and actual exit of 100 kPa, x = 1.0. Find its first law (isentropic) and its second law efficiencies.

Solution:

C.V. Steam turbine

Energy Eq.4.13: $w = h_i - h_e$

Entropy Eq.7.9: $s_e = s_i + s_{gen}$

Inlet state: Table B.1.3 $h_i = 3445.2$ kJ/kg; $s_i = 7.0900$ kJ/kg K

Exit (actual) state: Table B.1.2 $h_e = 2675.5$; $s_e = 7.3593$ kJ/kg K

Actual turbine energy equation

$$w = h_i - h_e = 769.7 \text{ kJ/kg}$$

Ideal turbine reversible process so $s_{gen} = 0$ giving

$$s_{es} = s_i = 70900 = 1.3025 + x_{es} \times 6.0568$$

$$x_{es} = 0.9555, \quad h_{es} = 417.4 + 0.9555 \times 2258.0 = 2575.0 \text{ kJ/kg}$$

The energy equation for the ideal gives

$$w_s = h_i - h_{es} = 870.2 \text{ kJ/kg}$$

The first law efficiency is the ratio of the two work terms

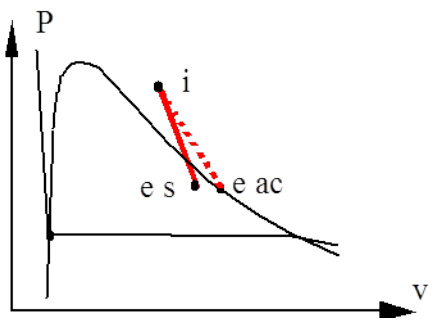
$$\eta_s = w/w_s = \mathbf{0.885}$$

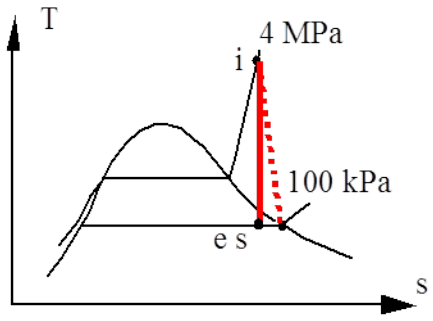
The reversible work for the actual turbine states is, Eq.8.29

$$w^{rev} = (h_i - h_e) + T_o(s_e - s_i)$$
$$= 769.7 + 298.2(7.3593 - 7.0900)$$
$$= 769.7 + 80.3 = 850.0 \text{ kJ/kg}$$

Second law efficiency Eq.8.31

$$\eta_{2^{nd}\,Law} = w/w_{rev} = 769.7/850.0 = \mathbf{0.906}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.106

Find the second law efficiency for the compressed air system in Problem 8.65. Consider the total system from the inlet to the final point of use.

In the total system the exergy increase in the air from inlet to final exit point is the gain and the source is the compressor work input.

Compressor. Reversible adiabatic, constant s: $s_2 = s_1$

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300\left(\frac{600}{100}\right)^{0.2857} = 500.5 \text{ K}$$

$$\psi_2 - \psi_1 = (h_2 - h_1) - T_0(s_2 - s_1) = h_2 - h_1 = C_{P0}(T_2 - T_1)$$
$$= 1.004\ (500.5 - 300) = 201.3 \text{ kJ/kg} = -w_C$$

From inlet, state 1 to final point of use state 3.

$$\psi_3 - \psi_1 = (h_3 - h_1) - T_0(s_3 - s_1) = 0 - T_0[0 - R \ln(P_3/P_1)]$$
$$= T_0 R \ln(P_3/P_1) = 298.15 \times 0.287 \times \ln (600/100)$$
$$= 153.3 \text{ kJ/kg}$$

$$\eta_{II} = \frac{\psi_3 - \psi_1}{\psi_2 - \psi_1} = \frac{153.3}{201.3} = \mathbf{0.76}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.107

A turbine receives steam at 3000 kPa, 500^{o}C and has two exit flows, one at 1000 kPa, 350^{o}C with 20% of the flow and the remainder at 200 kPa, 200^{o}C. Find the isentropic and the second law efficiencies.

C.V. Steam turbine (x = 0.2 = extraction fraction)

Energy Eq.4.13: $w = h_1 - xh_2 - (1 - x)h_3$

Entropy Eq.7.9: $s_e = s_1 + s_{gen}$

Inlet state: Table B.1.3 $h_1 = 3456.48$ kJ/kg; $s_1 = 7.2337$ kJ/kg K

Extraction state: $h_2 = 3157.65$ kJ/kg, $s_2 = 7.3010$ kJ/kg K

Exit (actual) state: Table B.1.3 $h_3 = 2870.46$; $s_3 = 7.5066$ kJ/kg K

Actual turbine energy equation

$$w = 3456.48 - 0.2 \times 3157.65 - 0.8 \times 2870.46 = 528.58 \text{ kJ/kg}$$

Ideal turbine reversible process so $s_{gen} = 0$ giving

$$s_{2s} = s_1 = 7.2337 \Rightarrow h_{2s} = 3117.43 \text{ kJ/kg}$$

$$s_{3s} = s_1 = 7.2337 \Rightarrow h_{3s} = 2750.12 \text{ kJ/kg}$$

The energy equation for the ideal turbine gives

$$w_s = h_1 - xh_{2s} - (1 - x)h_{3s}$$

$$= 3456.48 - 0.2 \times 3117.43 - 0.8 \times 2750.12 = 632.9 \text{ kJ/kg}$$

The first law efficiency: $\eta_s = w/w_s =$ **0.835**

The reversible work for the actual turbine states is, Eq.8.29

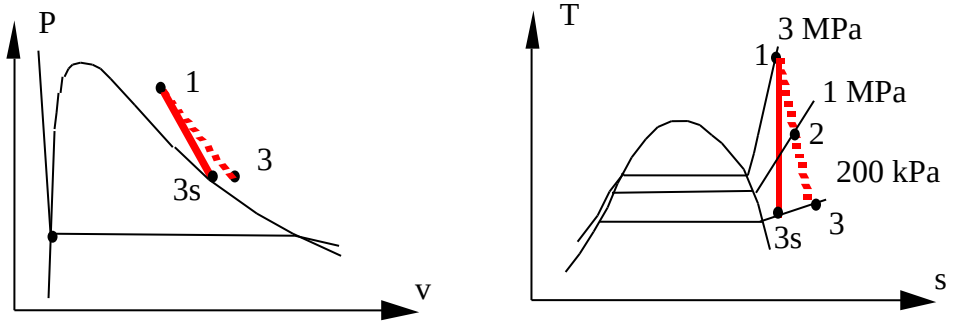
$$w^{rev} = [h_1 - xh_2 - (1 - x)h_3] - T_o[s_1 - xs_2 - (1 - x)s_3]$$

$$= 528.58 - 298.2(7.2337 - 0.2 \times 7.301 - 0.8 \times 7.5066)$$

$$= 528.58 + 69.1 = 597.68 \text{ kJ/kg}$$

Second law efficiency Eq.8.31

$$\eta_{II} = w/w_{rev} = 528.58/597.68 =$$ **0.884**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.108

Steam enters a turbine at 25 MPa, 550°C and exits at 5 MPa, 325°C at a flow rate of 70 kg/s. Determine the total power output of the turbine, its isentropic efficiency and the second law efficiency.

Solution:

$h_i = 3335.6$ kJ/kg, $s_i = 6.1765$ kJ/kg K,

$h_e = 2996.5$ kJ/kg, $s_e = 6.3289$ kJ/kg K

Actual turbine: $w_{T,ac} = h_i - h_e = 339.1$ kJ/kg

$$\dot{W} = \dot{m}\, w_{T,ac} = 70 \times 339.1 = \mathbf{23\ 740\ kW}$$

Isentropic turbine has a different exit state: $s_{e,s} = s_i \Rightarrow h_{e,s} = 2906.6$ kJ/kg

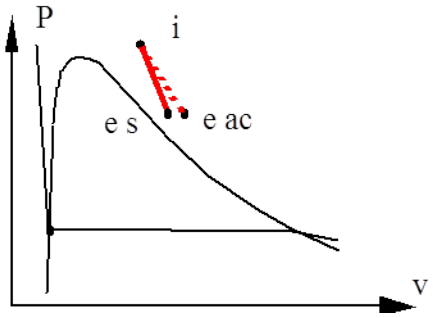
$$w_{T,s} = h_i - h_{e,s} = 429 \text{ kJ/kg}$$

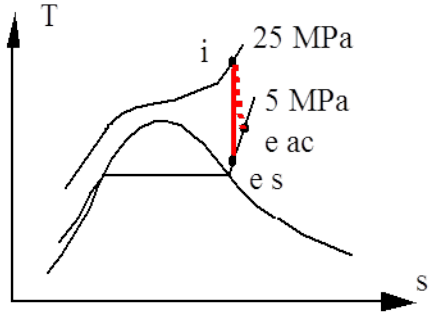
Rev. turbine has the same exit state as the actual turbine:

$$w_{rev} = w_{T,ac} + T_0(s_e - s_i) = 339.1 + 45.44 = 384.54 \text{ kJ/kg}$$

Eq.7.27: $\eta_T = w_{T,ac}/w_{T,s} = 339.1/429 = \mathbf{0.79}$

Eq.8.31: $\eta_{II} = w_{T,ac}/w_{rev} = 339.1/384.54 = \mathbf{0.88}$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.109

A heat engine operating with an evironment at 298 K produces 5 kW of power output with a first law efficiency of 50%. It has a second law efficiency of 80% and T_L = 310 K. Find all the energy and exergy transfers in and out.

Solution:

From the definition of the first law efficiency (conversion efficiency)

$$\dot{Q}_H = \dot{W} / \eta_I = \frac{5}{0.5} = \mathbf{10\ kW}$$

Energy Eq.: $\dot{Q}_L = \dot{Q}_H - \dot{W} = 10 - 5 = \mathbf{5\ kW}$

Exergy output: $\dot{\Phi}_W = \dot{W} = \mathbf{5\ kW}$

From the definition of the second law efficiency $\eta_{II} = \dot{W}/\dot{\Phi}_H$, this requires that we assume the exergy rejected at 310 K is lost and not counted, otherwise the efficiency should be $\eta_{II} = \dot{W}/(\dot{\Phi}_H - \dot{\Phi}_L)$.

Exergy from source: $\dot{\Phi}_H = (1 - \frac{T_o}{T_H})\, \dot{Q}_H = \dot{W}/\eta_{II} = \frac{5}{0.8} = \mathbf{6.25\ kW}$

Exergy rejected: $\dot{\Phi}_L = (1 - \frac{T_o}{T_L})\, \dot{Q}_L = (1 - \frac{298}{310})\, 5 = \mathbf{0.194\ kW}$

Notice from the $\dot{\Phi}_H$ form we could find the single characteristic T_H as

$$(1 - \frac{T_o}{T_H}) = 6.25\ \text{kW} / \dot{Q}_H = 0.625 \quad \Rightarrow \quad T_H = 795\ \text{K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.110

A flow of nitrogen, 0.1 kg/s, comes out of a compressor stage at 500 kPa, 500 K and is now cooled to 310 K in a counterflowing intercooler by liquid water at 125 kPa, 15°C which leaves at 22°C. Find the flowrate of water and the second law efficiency for the heat exchanger.

Solution:

Continuity eq.: $\dot{m}_1 = \dot{m}_2 = \dot{m}_{H2O}$; $\dot{m}_3 = \dot{m}_4 = \dot{m}_{N2}$

Energy eq.: $0 = \dot{m}_{N2}(h_3 - h_4) + \dot{m}_{H2O}(h_2 - h_1)$

Entropy Eq.7.7: $0 = \dot{m}_{N2}(s_3 - s_4) + \dot{m}_{H_2O}(s_2 - s_1) + \dot{S}_{gen}$

Due to the lower range of temperature we will use constant specific heats from A.5 and A.4 so the energy equation is approximated as

$$0 = \dot{m}_{H2O} C_{pH2O}(T_2 - T_1) + \dot{m}_{N2} C_p (T_3 - T_4)$$

Now solve for the water flow rate

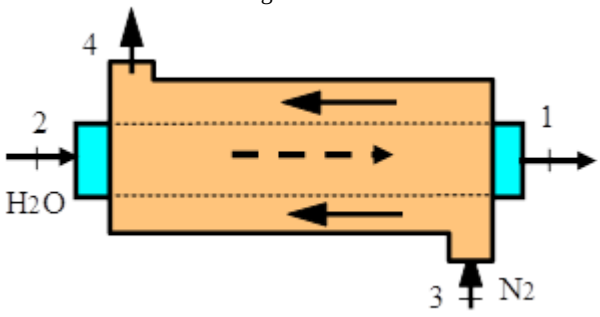
$$\dot{m}_{H2O} = \dot{m}_{N2} C_{pN2}(T_3 - T_4) / [C_{pH2O}(T_1 - T_2)]$$
$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \times (500 - 310) \text{ K} / [4.18 \times (22 - 15) \text{ kJ/kg}]$$
$$= \mathbf{0.677 \text{ kg/s}}$$

The second law efficiency is the exergy gain over the exergy source so we need exergy change in both flows.

$$\dot{m}_{N2}(\psi_4 - \psi_3) = \dot{m}_{N2} C_P [T_4 - T_3 - T_0 \ln(T_4/T_3)]$$
$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \times [310 - 500 - 298.15 \ln \frac{310}{500}] \text{ K} = -4.95 \text{ kW}$$

$$\dot{m}_{H_2O}(\psi_1 - \psi_2) = \dot{m}_{H_2O} C_P [T_1 - T_2 - T_0 \ln(T_1/T_2)]$$
$$= 0.677 \text{ kg/s} \times 4.18 \text{ kJ/kgK} [22 - 15 - 298.15 \ln(\frac{295}{288})] \text{ K} = -0.45 \text{ kW}$$

The nitrogen loses exergy as it cools, but the water also loses why? The water is brought closer to T_0 as it is being heated up which is closer to zero exergy. Both exergies drops and equals total exergy destruction ($T_0 S_{gen} = 5.4$ kW) $\eta_{II} < \mathbf{0}$!.



A hydraulic motor driven compressor, intercooler in pipe between the two stages.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.111

Air flows into a heat engine at ambient conditions 100 kPa, 300 K, as shown in Fig. P8.111. Energy is supplied as 1200 kJ per kg air from a 1500 K source and in some part of the process a heat transfer loss of 300 kJ/kg air happens at 750 K. The air leaves the engine at 100 kPa, 800 K. Find the first and the second law efficiencies.

C.V. Engine out to reservoirs

$$h_i + q_{1500} = q_{750} + h_e + w$$

$$w_{ac} = h_i + q_{1500} - q_{750} - h_e$$

$$= 300.47 + 1200 - 300 - 822.20 = 378.27 \text{ kJ/kg}$$

$$\eta_{TH} = w/q_{1500} = \mathbf{0.3152}$$

For second law efficiency also a q to/from ambient

$$s_i + (q_{1500}/T_H) + (q_0/T_0) = (q_{750}/T_m) + s_e$$

$$q_0 = T_0(s_e - s_i) + (T_0/T_m)q_{750} - (T_0/T_H)q_{1500}$$

$$= 300\left(7.88514 - 6.86925 - 0.287 \ln\frac{100}{100}\right) + \frac{300}{750}\,300$$

$$-(300/1500)\,1200 = 184.764 \text{ kJ/kg}$$

$$w^{rev} = h_i - h_e + q_{1500} - q_{750} + q_0 = w_{ac} + q_0 = 563.03 \text{ kJ/kg}$$

$$\eta_{II} = w_{ac}/w_{rev} = 378.27/563.03 = \mathbf{0.672}$$

Comment: You could also have defined the second law efficiency as

Exergy in: $\varphi_H = (1\text{-}T_0/T_H)\, q_{1500} = 0.80 \times 1200 = 960$ kJ/kg

$$\eta_{II} = w_{ac}/\varphi_H = 378.27 / 960 = 0.394$$

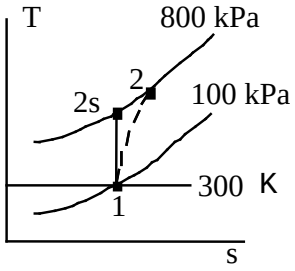
This measure places zero value of the loss at 750 K, zero exergy value for the two flow terms.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.112

Air enters a compressor at ambient conditions, 100 kPa, 300 K, and exits at 800 kPa. If the isentropic compressor efficiency is 85%, what is the second-law efficiency of the compressor process?

Solution:



Ideal (isentropic, Eq.6.23)

$$T_{2s} = 300(8)^{0.286} = 543.8 \text{ K}$$

$$-w_s = 1.004(543.8 - 300) = 244.6 \text{ kJ/kg}$$

$$-w = \frac{-w_s}{\eta_s} = \frac{244.6}{0.85} = 287.8 \text{ kJ/kg}$$

Actual exit temperature

$$T_2 = T_1 + \frac{-w}{C_{P0}} = 300 + \frac{287.8}{1.004} = 586.8 \text{ K}$$

Eq.6.16: $s_2 - s_1 = 1.004 \ln(586.8/300) - 0.287 \ln 8 = 0.07645$ kJ/kgK

Exergy, Eq.8.23

$$\psi_2 - \psi_1 = (h_2 - h_1) - T_0(s_2 - s_1) = 287.8 - 300(0.07645) = 264.9 \text{ kJ/kg}$$

2nd law efficiency, Eq.8.32 or 8.34 (but for a compressor):

$$\eta_{II} = \frac{\psi_2 - \psi_1}{-w} = \frac{264.9}{287.8} = \mathbf{0.92}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.113

Consider that the air in the previous problem after the compressor flows in a pipe to an air tool and at that point the temperature has dropped to ambient 300 K and an air pressure of 750 kPa. What is the second law efficiency for the total system?

C.V. Compressor

Energy: $0 = h_1 - h_2 + w_C$; Entropy: $0 = s_1 - s_2 + 0$

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300\left(\frac{800}{100}\right)^{0.2857} = 543.4 \text{ K}$$

Exergy increase through the compressor matches with the ideal compressor work

$$w_{C\,s} = h_2 - h_1 = C_P\,(T_2 - T_1) = 1.004\,(543.4 - 300)\text{ kJ/kg} = 244.4\text{ kJ/kg}$$

The actual compressor work is

$$w_{C\,ac} = w_{C\,s} / \eta_{C\,s} = 244.4/0.85 = 287.5\text{ kJ/kg}$$

From inlet, state 1 to final point of use state 3.

$$\psi_3 - \psi_1 = (h_3 - h_1) - T_0(s_3 - s_1) = 0 - T_0[0 - R\ln(P_3/P_1)]$$
$$= T_0\,R\ln(P_3/P_1) = 298.15\text{ K} \times 0.287\text{ kJ/kgK} \times \ln(750/100)$$
$$= 172.4\text{ kJ/kg}$$

So then the second law efficiency is the gain $(\psi_3 - \psi_1)$ over the source $w_{C\,ac}$ as

$$\eta_{II} = \frac{\psi_3 - \psi_1}{w_{C\,ac}} = \frac{172.4}{287.5} = \mathbf{0.6}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.114

A compressor is used to bring saturated water vapor at 1 MPa up to 15 MPa, where the actual exit temperature is 650°C. Find the irreversibility and the second-law efficiency.

Solution:

Inlet state: Table B.1.2 $h_i = 2778.08$ kJ/kg, $s_i = 6.5864$ kJ/kg K

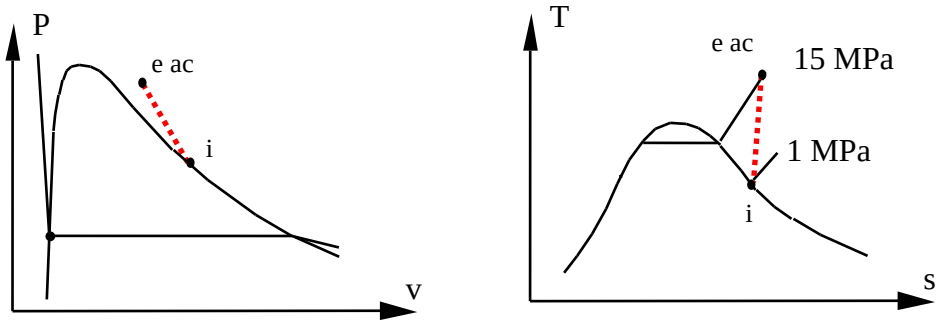
Actual compressor Table B.1.3: $h_{e,ac} = 3712.32$ kJ/kg, $s_{e,ac} = 6.8223$ kJ/kg K

Energy Eq. Actual compressor: $-w_{c,ac} = h_{e,ac} - h_i = 934.2$ kJ/kg

From Eq.8.13: $i = T_0(s_{e,ac} - s_i) = 298.15\ (6.8223 - 6.5864) =$ **70.33 kJ/kg**

From Eq.8.15: $w_{rev} = i + w_{c,ac} = 70.33 - 934.2 = -863.87$ kJ/kg

$$\eta_{II} = -w_{rev}/w_{c,ac} = 863.87/934.2 = \mathbf{0.925}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.115

Use the exergy equation to analyze the compressor in Example 4.8 to find its second law efficiency assuming an ambient at 20^{o}C.

C.V. The R-134a compressor. Steady flow. We need to find the reversible work and compare that to the actual work.

Notice the heat loss goes out to ambient T and has thus 0 exergy.

Exergy eq.: 8.38: $0 = \dot{m}(\psi_1 - \psi_2) + (-\dot{W}^{rev}_{comp}) + 0$

$$-\dot{W}^{rev}_{comp} = \dot{m} [h_2 - h_1 - T_o (s_2 - s_1)]$$

$$= 0.1 \text{ kg/s } [435.1 - 387.2 - 293.15 \text{ K} \times (1.7768 - 1.7665) \frac{\text{kJ}}{\text{kg K}}]$$

$$= 4.5 \text{ kW}$$

$$\eta_{II} = -\dot{W}^{rev}_{comp} / -\dot{W}^{ac}_{comp} = \frac{4.5}{5} = \mathbf{0.90}$$

For a real device this is a little high.

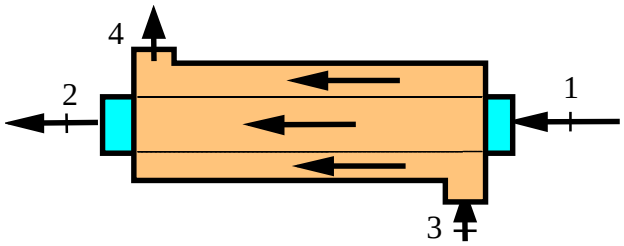
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.116

Calculate the second law efficiency of the coflowing heat exchanger in Problem 7.113 with an ambient at 17°C.

Solution:

C.V. Heat exchanger, steady 2 flows in and two flows out.



First solve for the exit temperature in Problem 7.113

C.V. Heat exchanger, steady 2 flows in and two flows out.

Energy Eq.4.10: $\dot{m}_{O2}h_1 + \dot{m}_{N2}h_3 = \dot{m}_{O2}h_2 + \dot{m}_{N2}h_4$

Same exit tempearture so $T_4 = T_2$ with values from Table A.5

$$\dot{m}_{O2}C_{P\,O2}T_1 + \dot{m}_{N2}C_{P\,N2}T_3 = (\dot{m}_{O2}C_{P\,O2} + \dot{m}_{N2}C_{P\,N2})T_2$$

$$T_2 = \frac{0.5 \times 0.922 \times 290 + 0.6 \times 1.042 \times 500}{0.5 \times 0.922 + 0.6 \times 1.042} = \frac{446.29}{1.0862} = 410.9 \text{ K}$$

The second law efficiency for a heat exchanger is the ratio of the exergy gain by one fluid divided by the exergy drop in the other fluid. We thus have to find the change of exergy in both flows. For each flow exergy in Eq.8.23 include mass flow rate as in Eq.8.38

For the oxygen flow:

$$\dot{m}_{O2}(\psi_2 - \psi_1) = \dot{m}_{O2}\,[\,h_2 - h_1 - T_o\,(\,s_2 - s_1\,)\,]$$

$$= \dot{m}_{O2}\,[\,C_P(T_2 - T_1) - T_o\,[\,C_P \ln(T_2 / T_1) - R \ln(P_2 / P_1)\,]$$

$$= \dot{m}_{O2}C_P\,[\,T_2 - T_1 - T_o \ln(T_2 / T_1)\,]$$

$$= 0.5 \times 0.922\,[\,410.9 - 290 - 290 \ln(410.9/290)\,] = 9.148 \text{ kW}$$

For the nitrogen flow

$$\dot{m}_{N2}(\psi_3 - \psi_4) = \dot{m}_{N2}C_P\,[\,T_3 - T_4 - T_o \ln(T_3 / T_4)\,]$$

$$= 0.6 \times 1.042\,[\,500 - 410.9 - 290 \ln(500/410.9)\,] = 20.122 \text{ kW}$$

From Eq.8.32

$$\eta_{2^{nd}\,Law} = \frac{\dot{m}_{O2}(\psi_1 - \psi_2)}{\dot{m}_{N2}(\psi_3 - \psi_4)} = \frac{9.148}{20.122} = \mathbf{0.513}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.117

An air-compressor receives air at 290 K, 100 kPa and brings it up to a higher pressure in an adiabatic process. The actual specific work is 210 kJ/kg and the isentropic efficiency is 82%. Find the exit pressure and the second law efficiency.

C.V. Compressor. Assume adiabatic and neglect kinetic energies.

Energy Eq.4.13: $w = h_1 - h_2$

Entropy Eq.7.9: $s_2 = s_1 + s_{gen}$

We have two different cases, the ideal and the actual compressor.

$-w_{C,AC} = h_{2,AC} - h_1 = 210$ kJ/kg $= w_{c,s} / \eta_c$

$T_{2,AC} = T_1 - w_{C,AC} / C_P = 290 + 210 / 1.004 = 499.2$ K

For the isentropic compressor we get

$-w_{c,s} = -\eta_c \, w_{C,AC} = 0.82 \times 210 = 172.2$ kJ/kg $= h_{2,s} - h_1$

$T_{2,s} = T_1 - w_{c,s} / C_P = 290 + 172.2/1.004 = 461.5$ K

$P_2 = P_1 (T_{2,s} / T_1)^{k/k-1} = 100 \, (461.5/290)^{3.5} =$ **508.4 kPa**

Now the

$$w^{rev} = (\psi_1 - \psi_{2,AC}) = (h_1 - h_{2,AC}) + T_o(s_{2,AC} - s_1)$$

$$= w_{C,AC} + T_o[\, C_P \ln(T_{2,ac} / T_1) - R \ln (P_2 / P_1)]$$

$$= -210 + 298.15 \, [\, 1.004 \ln(\frac{499.2}{290}) - 0.287 \ln(\frac{508.4}{100}) \,]$$

$$= -210 + 23.4 = -186.6 \text{ kJ/kg}$$

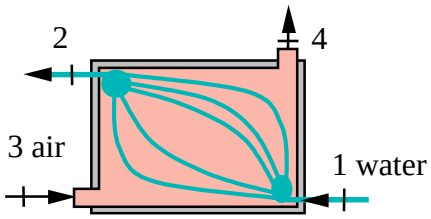
$$\eta_{II} = w^{rev} / w_{C,AC} = \frac{-186.6}{-210} = \mathbf{0.88}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.118

A flow of 2 kg/s water at 1000 kPa, 80°C goes into a constant pressure boiler where the water is heated to 400°C. Assume the hot gases that heats the water is air coming in at 1200 K and leaving at 900 K as in a counter flowing heat exchanger. Find the total rate of irreversibility in the process and the second law efficiency of the boiler setup.

Solution:
C.V. Heat exchanger, steady flow 1 inlet and 1 exit for air and water each. The two flows exchange energy with no heat transfer to/from the outside. We need to find the air mass flow rate.



Energy Eq.: $\dot{m}_{H2O}(h_2 - h_1) = \dot{m}_{air}(h_3 - h_4)$

$$\dot{m}_{air} = \dot{m}_{H2O}\frac{h_2 - h_1}{h_3 - h_4} = 2\,\frac{3263.88 - 335.64}{1277.81 - 933.15} = 16.992 \text{ kg/s}$$

Exergy increase of the water flow

$$\dot{m}_{H2O}(\psi_2 - \psi_1) = \dot{m}_{H2O}[h_2 - h_1 - T_o(s_2 - s_1)]$$
$$= 2\,[3263.88 - 335.64 - 298.15(7.465 - 1.0746)]$$
$$= 2\,[\,2928.24 - 1905.3\,] = 2045.9 \text{ kW}$$

Exergy decrease of the air flow

$$\dot{m}_{air}(\psi_3 - \psi_4) = \dot{m}_{air}[h_3 - h_4 - T_o(s_3 - s_4)]$$
$$= 16.992\,[1277.81 - 933.15 - 298.15(8.34596 - 8.01581)]$$
$$= 4183.9 \text{ kW}$$

The irreversibility is the destruction of exergy

$$\dot{I} = \dot{\Phi}_{destruction} = \dot{\Phi}_{in} - \dot{\Phi}_{out} = 4183.9 \text{ kW} - 2045.9 \text{ kW} = \mathbf{2138\ kW}$$

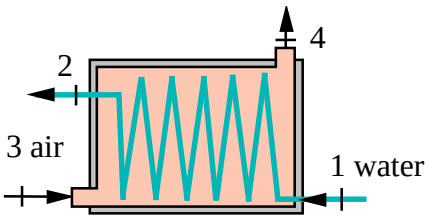
$$\eta_{2^{nd}\,Law} = \frac{\dot{m}_{H2O}(\psi_2 - \psi_1)}{\dot{m}_{air}(\psi_3 - \psi_4)} = \frac{2045.9}{4183.9} = \mathbf{0.489}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.119

A heat exchanger brings 10 kg/s water from 100°C to 500°C at 2000 kPa using air coming in at 1400 K and leaving at 460 K. What is the second law efficiency?

Solution:
C.V. Heat exchanger, steady flow 1 inlet and 1 exit for air and water each. The two flows exchange energy with no heat transfer to/from the outside. We need to find the air mass flow rate.



Energy Eq.: $\dot{m}_{H2O}(h_2 - h_1) = \dot{m}_{air}(h_3 - h_4)$

$$\dot{m}_{air} = \dot{m}_{H2O}\frac{h_2 - h_1}{h_3 - h_4} = 10\,\frac{3467.55 - 420.45}{1515.27 - 462.34} = 28.939 \text{ kg/s}$$

Exergy increase of the water flow

$$\dot{m}_{H2O}(\psi_2 - \psi_1) = \dot{m}_{H2O}[h_2 - h_1 - T_o(s_2 - s_1)]$$
$$= 10\,[\,3467.55 - 420.45 - 298.15(7.4316 - 1.3053)]$$
$$= 10\,[\,3047.1 - 1826.56\,] = 12\,205 \text{ kW}$$

Exergy decrease of the air flow

$$\dot{m}_{air}(\psi_3 - \psi_4) = \dot{m}_{air}[h_3 - h_4 - T_o(s_3 - s_4)]$$
$$= 28.939\,[1515.27 - 462.34 - 298.15(8.52891 - 7.30142)]$$
$$= 19\,880 \text{ kW}$$

$$\eta_{2^{nd}\,Law} = \frac{\dot{m}_{H2O}(\psi_2 - \psi_1)}{\dot{m}_{air}(\psi_3 - \psi_4)} = \frac{12\,205}{19\,880} = \mathbf{0.614}$$

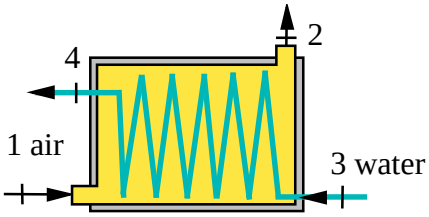
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.120

Calculate the second law efficiency of the counter flowing heat exchanger in Problem 7.105 with an ambient at 20°C.

Solution:

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for air and water each. The two flows exchange energy with no heat transfer to/from the outside.



Heat exchanger Prob 7.105 with T_o = 20°C solve first for state 4.

Energy Eq.4.10: $\dot{m}_{AIR}\Delta h_{AIR} = \dot{m}_{H2O}\Delta h_{H2O}$

From A.7: $h_1 - h_2 = 1046.22 - 401.3 = 644.92$ kJ/kg

From B.1.2 $h_3 = 83.94$ kJ/kg; $s_3 = 0.2966$ kJ/kg K

$h_4 - h_3 = (\dot{m}_{AIR}/\dot{m}_{H2O})(h_1 - h_2) = (2/0.5)644.92 = 2579.68$ kJ/kg

$h_4 = h_3 + 2579.68 = 2663.62 \; < \; h_g$ at 200 kPa

$T_4 = T_{sat} = 120.23$°C,

$x_4 = (2663.62 - 504.68)/2201.96 = 0.9805$,

$s_4 = 1.53 + x_4\, 5.597 = 7.01786$ kJ/kg K

We need the change in exergy for each flow from Eq.8.23

$(\psi_1 - \psi_2) = (h_1 - h_2) + T_o(s_2 - s_1)$

$= (1046.2 - 401.3) + 293.2(7.1593 - 8.1349 - 0.287 \ln(100/125)$

$= 644.9 + 293.2(-0.91156) = 377.6$ kJ/kg

$(\psi_4 - \psi_3) = (h_4 - h_3) + T_o(s_4 - s_3)$

$= (2663.6 - 83.9) - 293.2(7.0179 - 0.2966)$

$= 2579.9 - 1970.7 = 609.0$

Efficiency from Eq.8.32

$$\eta_{2^{nd}\,Law} = [\dot{m}_w(\psi_4 - \psi_3)]/[\dot{m}_A(\psi_1 - \psi_2)]$$

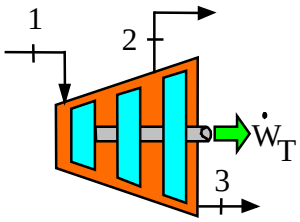
$$= (0.5 \times 609.0)/(2 \times 377.6) = \mathbf{0.403}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.121

A steam turbine receives 5 kg/s steam at 400°C, 10 MPa. One flow of 0.8 kg/s is extracted at 3 MPa as saturated vapor and the remainder runs out at 1500 kPa with a quality of 0.975. Find the second law efficiency of the turbine.

C.V. Turbine. Steady flow and adiabatic q = 0.



Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$;

Energy Eq.4.10: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3 + \dot{W}$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3$

State 1: $h_1 = 3096.46$ kJ/kg, $s_1 = 6.2119$ kJ/kg-K

State 2: $h_2 = 2804.14$ kJ/kg, $s_2 = 6.1869$ kJ/kg-K

State 3: $h_3 = 844.87 + 0.975 \times 1947.28 = 2743.5$ kJ/kg,

$s_3 = 2.315 + 0.975 \times 4.1298 = 6.34156$ kJ/kg-K

$$\dot{W} = \dot{m}_1 h_1 - \dot{m}_2 h_2 - \dot{m}_3 h_3 = 5 \times 3096.46 - 0.8 \times 2804.14 - 4.2 \times 2743.5$$
$$= 1716 \text{ kW}$$

This work is now compared to the reversible work possible

$$\dot{W}^{rev} = \dot{m}_1 \psi_1 - \dot{m}_2 \psi_2 - \dot{m}_3 \psi_3$$

$$= \dot{m}_1 h_1 - \dot{m}_2 h_2 - \dot{m}_3 h_3 - T_o [\, \dot{m}_1 s_1 - \dot{m}_2 s_2 - \dot{m}_3 s_3 \,]$$
$$= 1716 \text{ kW} - 298.15 [5 \times 6.2119 - 0.8 \times 6.1869 - 4.2 \times 6.34156] \text{ kW}$$
$$= 1716 \text{ kW} + 156.4 \text{ kW} = 1872 \text{ kW}$$

$$\eta_{2^{nd}\,Law} = \dot{W} / \dot{W}^{rev} = \frac{1716}{1872} = \mathbf{0.917}$$

8.122

Calculate the irreversibility for the process described in Problem 4.154, assuming that heat transfer is with the surroundings at 17°C.

Solution:

C.V. Cylinder volume out to $T_o = 17\ ^oC$.

Continuity Eq.4.15: $m_2 - m_1 = m_{in}$

Energy Eq.4.16: $m_2u_2 - m_1u_1 = m_{in}h_{line} + {}_1Q_2 - {}_1W_2$

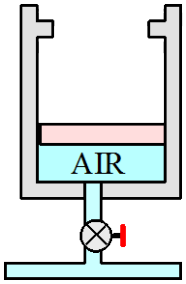
Entropy Eq.7.12: $m_2 s_2 - m_1s_1 = m_is_i + {}_1Q_2 / T_o + {}_1S_{2\ gen}$

Process: P_1 is constant to stops, then constant V to state 2 at P_2

State 1: P_1, T_1 $\quad m_1 = \dfrac{P_1V}{RT_1} = \dfrac{300 \times 0.25}{0.287 \times 290.2} = 0.90$ kg

State 2:

Open to $P_2 = 400$ kPa, $T_2 = 350$ K



$$m_2 = \frac{400 \times 1}{0.287 \times 350} = 3.982 \text{ kg}$$

$$m_i = 3.982 - 0.90 = 3.082 \text{ kg}$$

Only work while constant P

$${}_1W_2 = P_1(V_2 - V_1) = 300(1 - 0.25) = 225 \text{ kJ}$$

Energy eq.:

$${}_1Q_2 = m_2u_2 - m_1u_1 + {}_1W_2 - m_ih_i$$

$$= 3.982 \times 0.717 \times 350 - 0.90 \times 0.717 \times 290.2 + 225$$

$$- 3.082 \times 1.004 \times 600 = -819.2 \text{ kJ}$$

Entropy eq. gives

$$T_o\ {}_1S_{2\ gen} = I = T_o\ [\ m_1\ (s_2 - s_1) + m_i\ (s_2 - s_i)] - {}_1Q_2$$

$$= 290.15[0.9(C_p \ln \frac{350}{290} - R \ln \frac{400}{300}) + 3.082(C_p \ln \frac{350}{600} - R \ln \frac{400}{500})]$$

$$- (\ -\ 819.2 \text{ kJ})$$

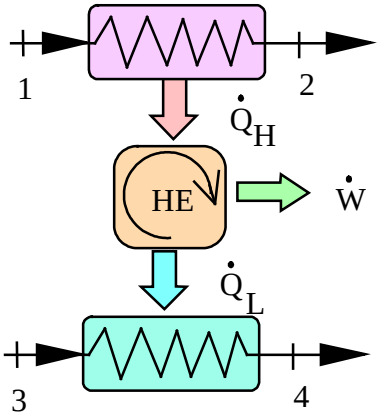
$$= 290.15\ (0.0956 - 1.4705) + 819.2$$

$$= \mathbf{420.3\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.123

The high-temperature heat source for a cyclic heat engine is a steady flow heat exchanger where R-134a enters at 80°C, saturated vapor, and exits at 80°C, saturated liquid at a flow rate of 5 kg/s. Heat is rejected from the heat engine to a steady flow heat exchanger where air enters at 150 kPa and ambient temperature 20°C, and exits at 125 kPa, 70°C. The rate of irreversibility for the overall process is 175 kW. Calculate the mass flow rate of the air and the thermal efficiency of the heat engine.



C.V. R-134a Heat Exchanger,

$\dot{m}_{R134a}$ = 5 kg/s, Table B.5.1

Inlet: $T_1 = 80^oC$, sat. vapor $x_1 = 1.0$,

$h_1 = h_g = 429.189$ kJ/kg,

$s_1 = s_g = 1.6862$ kJ/kg-K

Exit: $T_2 = 80^oC$, sat. liquid $x_2 = 0.0$

$h_2 = h_f = 322.794$ kJ/kg,

$s_2 = s_f = 1.3849$ kJ/kg-K

C.V. Air Heat Exchanger, $C_p = 1.004$ kJ/kg-K, $R = 0.287$ kJ/kg-K

Inlet: $T_3 = 20^oC$, $P_3 = 150$ kPa Exit: $T_4 = 70^oC$, $P_4 = 125$ kPa

$s_4 - s_3 = C_p \ln (T_4 / T_3) - R \ln(P_4 / P_3) = 0.2103$ kJ/kg-K

Entropy Eq. for the total system as control volume (since we know $\dot{I}$):

$$\dot{I} / T_o = \dot{S}_{net} = \dot{m}_{R134a} (s_2 - s_1) + \dot{m}_{air}(s_4 - s_3)$$

$$\dot{m}_{air} = \frac{\dot{I}/T_o - \dot{m}_{R134a}(s_2 - s_1)}{s_4 - s_3} = \frac{(175/293.15) - 5\,(1.3849 - 1.6862)}{0.2103} \frac{\text{kW/K}}{\text{kJ/kg-K}}$$

= **10.0 kg/s**

Energy Eq. for each line: $\dot{Q} + \dot{m}h_{in} = \dot{m}h_{ex} + \dot{W}$; $\dot{W} = 0$

R-134a: ${}_1\dot{Q}_2 = -\dot{Q}_H = \dot{m}_{R134a}(h_2 - h_1) = -532$ kW

Air: $\dot{Q}_L = {}_3\dot{Q}_4 = \dot{m}_{air}(h_4 - h_3) = \dot{m}_{air}\, C_p(T_4 - T_3) = 501.8$ kW

Control volume heat engine

$$\dot{W}_{net} = \dot{Q}_H - \dot{Q}_L = 532 - 501.8 = 30.2 \text{ kW};$$

$$\eta_{th} = \dot{W}_{net} / \dot{Q}_H = \mathbf{0.057,} \quad \mathbf{or\ \ 5.7\%}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.124

A cylinder with a linear spring-loaded piston contains carbon dioxide gas at 2 MPa with a volume of 50 L. The device is of aluminum and has a mass of 4 kg. Everything (Al and gas) is initially at 200°C. By heat transfer the whole system cools to the ambient temperature of 25°C, at which point the gas pressure is 1.5 MPa. Find the exergy at the initial and final states and the destruction of exergy in the process.

State 1: $T_1 = 200\ ^oC, \quad v_1 = V_1/ m = 0.05 / 1.1186 = 0.0447\ m^3/kg$

State 2: $v_2 = v_1 \times (2 / 1.5) \times (298.15 / 473.15) = 0.03756\ m^3/kg$

The metal does not change volume, so the combined is using Eq.8.27 as

$$\phi_1 = m_{gas}\phi_{gas} + m_{Al}\phi_{Al}$$

$$= m_{gas}[u_1-u_o-T_o(s_1 - s_o)]_{cv} + m_{gas}P_o(v_1-v_o) + m_{Al}[u_1-u_o -T_o(s_1-s_o)]_{Al}$$

$$= m_{gas}C_v (T_1 - T_o) - m_{gas}T_o \left[C_p \ln \frac{T_1}{T_o} - R \ln \frac{P_1}{P_o}\right] + m_{gas}P_o (v_1 - v_o)$$

$$+ m_{Al} [C (T_1 - T_o) - T_oC \ln (T_1/T_o)]_{Al}$$

$$\phi_1 = 1.1186 \left[0.653(200-25) - 298.15 \left(0.842 \ln \frac{473.15}{298.15} - 0.18892 \ln \frac{2000}{100}\right)\right.$$

$$\left. + 100 (0.0447 - 0.5633) \right] + 4 \times 0.90 \left[200 -25 - 298.15 \ln \frac{473.15}{298.15} \right]$$

$$= 128.88 + 134.3 = \mathbf{263.2\ kJ}$$

$$\phi_2 = 1.1186 \left[0.653(25 - 25) - 298.15 \left(0.842 \ln \frac{298.15}{298.15} - 0.18892 \ln \frac{1500}{100}\right)\right.$$

$$\left. + 100 (0.03756 - 0.5633) \right] + 4 \times 0.9 \left[25 -25 - 298.15 \ln \frac{298.15}{298.15} \right]$$

$$= 111.82 + 0 = \mathbf{111.82\ kJ}$$

The irreversibility is as in Eq.8.38 integrated over time (no flow terms)

$${}_1I_2 = \phi_1 - \phi_2 + [1 - (T_0/T_H)]\ {}_1Q_2 - {}_1W_2{}^{AC} + P_om(V_2 - V_1)$$

$$= 263.2 - 111.82 + 0 - (-14) + 100 \times 1.1186 (0.03756 - 0.0447) = 164.58\ kJ$$

$$[({}_1S_{s\ gen} = 0.552\ kJ/K; \quad T_o\ {}_1S_{s\ gen} = 164.58\ kJ \quad \text{so OK }]$$

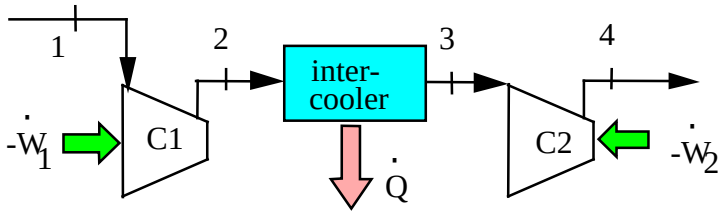
8.125

A two-stage compressor takes nitrogen in at 20°C, 150 kPa compresses it to 600 kPa, 450 K then it flows through an intercooler where it cools to 320 K and the second stage compresses it to 3000 kPa, 530 K. Find the specific exergy increase and the specific exergy destruction in each of the two compressor stages.

The setup is like this:



C.V.: Stage 1 nitrogen, Steady flow

Process: adibatic: $q = 0$, $s_{gen} = 0$

Energy Eq. 4.13: $-w_{C1} = h_2 - h_1$, Entropy Eq. 7.10: $0 = s_1 - s_2 + s_{gen\ C1}$

Assume constant $C_{P0} = 1.042$ from A.5 and Eq.6.16 for change in entropy

$$s_{gen\ C1} = s_2 - s_1 = C_{P0} \ln(T_2/T_1) - R \ln (P_2/P_1)$$

$$= 1.042 \ln(450/293.15) - 0.2968 \ln(600/150) = 0.0351 \text{ kJ/kgK}$$

$$\psi_{destruction\ C1} = T_o\, s_{gen\ C1} = 298.15 \text{ K} \times 0.0351 \text{ kJ/kgK} = \mathbf{10.46\ kJ/kg}$$

$$\psi_2 - \psi_1 = h_2 - h_1 - T_o\,(s_2 - s_1) = C_{P0}(T_2 - T_1) - T_o\,(s_2 - s_1)$$

$$= 1.042(450 - 293.15) - 298.15 \times 0.0351 = \mathbf{152.98\ kJ/kg}$$

$$s_{gen\ C2} = s_4 - s_3 = C_{P0} \ln(T_4/T_3) - R \ln (P_4/P_3)$$

$$= 1.042 \ln(530/320) - 0.2968 \ln(3000/600) = 0.0481 \text{ kJ/kgK}$$

$$\psi_{destruction\ C2} = T_o\, s_{gen\ C2} = 298.15 \text{ K} \times 0.0481 \text{ kJ/kgK} = \mathbf{14.34\ kJ/kg}$$

$$\psi_4 - \psi_3 = h_4 - h_3 - T_o\,(s_4 - s_3) = C_{P0}(T_4 - T_3) - T_o\,(s_4 - s_3)$$

$$= 1.042(530 - 320) - 298.15 \times 0.0481 = \mathbf{204.48\ kJ/kg}$$

Comment: Notice how the exergy increases are the enthalpy increase minus the exergy destruction.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.126

The intercooler in the previous problem uses cold liquid water to cool the nitrogen. The nitrogen flow is 0.1 kg/s and the liquid water inlet is 20°C and setup to flow in the opposite direction as the nitrogen so the water leaves at 35°C. Find the flow rate of the water and the exergy destruction in this intercooler.

C.V. Heat exchanger, steady 2 flows in and two flows out.

Continuity eq.: $\dot{m}_1 = \dot{m}_2 = \dot{m}_{H2O}$; $\dot{m}_3 = \dot{m}_4 = \dot{m}_{N2}$

Energy eq.: $0 = \dot{m}_{N2}(h_3 - h_4) + \dot{m}_{H2O}(h_2 - h_1)$

Entropy Eq.7.7: $0 = \dot{m}_{N2}(s_3 - s_4) + \dot{m}_{H_2O}(s_2 - s_1) + \dot{S}_{gen}$

Due to the lower range of temperature we will use constant specific heats from A.5 and A.4 so the energy equation is approximated as

$$0 = \dot{m}_{H2O} C_{pH2O}(T_2 - T_1) + \dot{m}_{N2} C_p (T_3 - T_4)$$

Now solve for the water flow rate

$$\dot{m}_{H2O} = \dot{m}_{N2} C_{pN2}(T_3 - T_4) / [C_{pH2O}(T_1 - T_2)]$$
$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \times (450 - 320) \text{ K} / [4.18 \times (35 - 20) \text{ kJ/kg}]$$
$$= \mathbf{0.216 \text{ kg/s}}$$

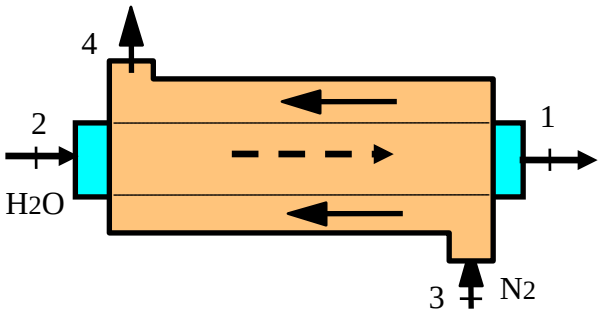
$$\dot{S}_{gen} = \dot{m}_{N2}(s_4 - s_3) + \dot{m}_{H_2O}(s_1 - s_2)$$

$$= \dot{m}_{N2} C_P \ln(T_4/T_3) + \dot{m}_{H_2O} C_P \ln(T_1/T_2)$$

$$= 0.1 \text{ kg/s} \times 1.042 \text{ kJ/kgK} \ln\frac{320}{450} + 0.216 \text{ kg/s} \times 4.18 \text{ kJ/kgK} \ln\frac{308}{293}$$

$$= -0.03552 + 0.04508 = 0.00956 \text{ kW/K}$$

$$\dot{\Phi}_{destruction} = \dot{I} = T_o \dot{S}_{gen} = 298.15 \text{ K} \times 0.00956 \text{ kW/K} = \mathbf{2.85 \text{ kW}}$$



A hydraulic motor driven compressor with intercooler in small pipe between the two stages.

8.127

Find the irreversibility in the cooling process of the glass plate in Problem 4.144.

In a glass factory a 2 m wide sheet of glass at 1500 K comes out of the final rollers that fix the thickness at 5 mm with a speed of 0.5 m/s. Cooling air in the amount of 20 kg/s comes in at 17°C from a slot 2 m wide and flows parallel with the glass. Suppose this setup is very long so the glass and air comes to nearly the same temperature (a co-flowing heat exchanger) what is the exit temperature?

Energy Eq.: $\dot{m}_{glass} h_{glass\ 1} + \dot{m}_{air} h_{air\ 2} = \dot{m}_{glass} h_{glass\ 3} + \dot{m}_{air} h_{air\ 4}$

$$\dot{m}_{glass} = \rho \dot{V} = \rho A V = 2500 \times 2 \times 0.005 \times 0.5 = 12.5 \text{ kg/s}$$

$$\dot{m}_{glass} C_{glass} (T_3 - T_1) + \dot{m}_{air} C_{Pa} (T_4 - T_2) = \varnothing$$

$$T_4 = T_3 \ , \ C_{glass} = 0.80 \text{ kJ/kg K}, \quad C_{Pa} = 1.004 \text{ kJ/kg K}$$

$$T_3 = \frac{\dot{m}_{glass} C_{glass} T_1 + \dot{m}_{air} C_{Pa} T_2}{\dot{m}_{glass} C_{glass} + \dot{m}_{air} C_{Pa}} = \frac{12.5 \times 0.80 \times 1500 + 20 \times 1.004 \times 290}{12.5 \times 0.80 + 20 \times 1.004}$$

$$= 692.3 \text{ K}$$

To find the irreversibility we need the entropy generation term

Entropy Eq.: $\dot{m}_{glass} s_{glass\ 1} + \dot{m}_{air} s_{air\ 2} + \dot{S}_{gen} = \dot{m}_{glass} s_{glass\ 3} + \dot{m}_{air} s_{air\ 4}$

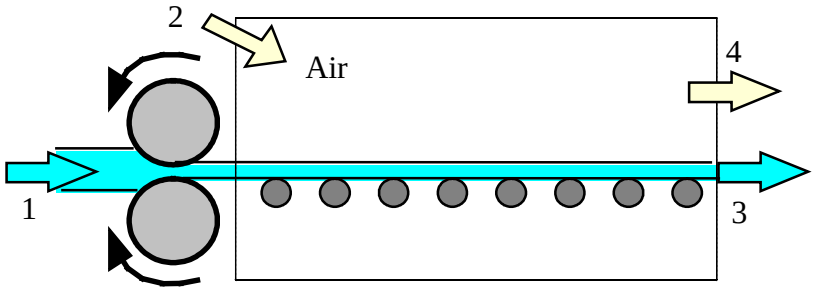
$$\dot{S}_{gen} = \dot{m}_{glass} (s_3 - s_1)_{glass} + \dot{m}_{air} (s_4 - s_2)_{air}$$

$$= \dot{m}_{glass} C_{glass} \ln(T_3 / T_1) + \dot{m}_{air} C_{Pa} \ln(T_4 / T_2)$$

$$= 12.5 \times 0.8 \times \ln(692.3 / 1500) + 20 \times 1.004 \times \ln(692.3/290)$$

$$= -7.732 \text{ kW/K} + 17.472 \text{ kW/K} = 9.74 \text{ kW/K}$$

$$\dot{I} = \dot{\Phi}_{destruction} = T_o \dot{S}_{gen} = 298.15 \text{ K} \times 9.74 \text{ kW/K} = \mathbf{2904\ kW}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.128

Air in a piston/cylinder arrangement is at 110 kPa, 25°C, with a volume of 50 L. It goes through a reversible polytropic process to a final state of 700 kPa, 500 K, and exchanges heat with the ambient at 25°C through a reversible device. Find the total work (including the external device) and the heat transfer from the ambient.

C.V. Total out to ambient

Energy: $m_a(u_2 - u_1) = {}_1Q_2 - {}_1W_{2,tot}$,

Entropy: $m_a(s_2 - s_1) = {}_1Q_2/T_0 + 0$

$m_a = 110 \times 0.05/0.287 \times 298.15 = 0.0643$ kg

$${}_1Q_2 = T_0 m_a(s_2 - s_1) = 298.15 \times 0.0643\big[7.3869 - 6.8631 - 0.287 \ln (700/110)\big] = -0.14 \text{ kJ}$$

$${}_1W_{2,tot} = {}_1Q_2 - m_a(u_2 - u_1)$$

$$= -0.14 - 0.0643 \times (359.844 - 213.037) = \mathbf{-9.58\ kJ}$$

This is identical to the reversible work in Eq.8.17 ($T_j = T_0$).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.129

A rigid container with volume 200 L is divided into two equal volumes by a partition. Both sides contains nitrogen, one side is at 2 MPa, 300°C, and the other at 1 MPa, 50°C. The partition ruptures, and the nitrogen comes to a uniform state at 100°C. Assuming the surroundings are at 25°C find the actual heat transfer and the irreversibility in the process.

Solution:

C.V. Total container

Continuity Eq.: $m_2 - m_A - m_B = 0$

Energy Eq.: $m_A(u_2 - u_1)_A + m_B(u_2 - u_1)_B = {}_1Q_2 - {}_1W_2$

Entropy Eq.: $m_A(s_2 - s_1)_A + m_B(s_2 - s_1)_B = {}_1Q_2/T_{sur} + {}_1S_{s\,gen}$

Process: $V = C \quad \Rightarrow \quad {}_1W_2 = 0$

From the initial state we get the mass as

$$m_2 = m_A + m_B = \frac{P_{A1}V_A}{RT_{A1}} + \frac{P_{B1}V_B}{RT_{B1}}$$

$$= \frac{2000\times0.1}{0.2968\times573.15} + \frac{1000\times0.1}{0.2968\times323.15} = 1.176 + 1.043 = 2.219 \text{ kg}$$

$$P_2 = m_2RT_2/V_{tot} = 2.219 \times 0.2968 \times 373.15/0.2 = 1228.8 \text{ kPa}$$

From the energy equation we get the heat transfer as the change in U

$${}_1Q_2 = m_AC_v(T_2 - T_1)_A + m_BC_v(T_2 - T_1)_B$$

$$= 1.176 \times 0.745 \times (100 - 300) + 1.043 \times 0.745 \times (100 - 50)$$

$$= \mathbf{-136.4\ kJ}$$

The entropy changes are found from Eq.8.16

$$(s_2 - s_1)_A = 1.042 \times \ln\frac{373.15}{573.15} - 0.2968 \times \ln\frac{1228.8}{2000} = -0.09356 \text{ kJ/kg K}$$

$$(s_2 - s_1)_B = 1.042 \times \ln\frac{373.15}{323.15} - 0.2968 \times \ln\frac{1228.8}{1000} = 0.0887 \text{ kJ/kg K}$$

The entropy generation follows from the entropy equation

$${}_1S_{2,gen} = 1.176\times (-0.09356) + 1.043\times 0.0887 + 136.4/298.15 = 0.4396 \text{ kJ/K}$$

Now the irreversibility comes from Eq. 10.13

$${}_1I_2 = T_0 \times {}_1S_{2,gen} = \mathbf{131.08\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.130

Consider the irreversible process in Problem 6.182. Assume that the process could be done reversibly by adding heat engines/pumps between tanks A and B and the cylinder. The total system is insulated, so there is no heat transfer to or from the ambient. Find the final state, the work given out to the piston and the total work to or from the heat engines/pumps.

C.V. Water $m_A + m_B$ + heat engines. No Qexternal, only ${}_1W_{2,cyl} + W_{HE}$

Continuity Eq.: $m_2 = m_{A1} + m_{B1} = 6$ kg,

Energy Eq.: $m_2u_2 - m_{A1}u_{A1} - m_{B1}u_{B1} = -{}_1W_{2,cyl} - W_{HE}$

Entropy Eq.: $m_2s_2 - m_{A1}s_{A1} - m_{B1}s_{B1} = \emptyset + \emptyset$

$v_{A1} = 0.06283$ m^3/kg, $u_{A1} = 3448.5$ kJ/kg, $s_{A1} = 7.3476$ kJ/kg-K,

$v_{B1} = 0.09053$ m^3/kg, $u_{B1} = 2843.7$ kJ/kg, $s_{B1} = 6.7428$ kJ/kg-K

$V_A = m_{A1}\, v_{A1} = 0.2513$ m^3; $V_B = m_{B1}v_{B1} = 0.1811$ m^3

$m_2s_2 = 4\times7.3476 + 2\times6.7428 = 42.876$ kJ/K $\Rightarrow$ $s_2 = 7.146$ kJ/kg K

If $P_2 < P_{lift} = 1.4$ MPa then

$V_{2'} = V_A + V_B = 0.4324$ m^3, $v_{2'} = 0.07207$ m^3/kg

$(P_{lift}, s_2) \Rightarrow v_2 = 0.20135 \Rightarrow V_2 = 1.208$ m$^3 > V_{2'}$ OK

$\Rightarrow P_2 = P_{lift} =$ **1.4 MPa** $u_2 = 2874.2$ kJ/kg

${}_1W_{2,cyl} = P_{lift}(V_2 - V_A - V_B) = 1400\times(1.208 - 0.4324) =$ **1085.84 kJ**

$W_{HE} = m_{A1}u_{A1} + m_{B1}u_{B1} - m_2u_2 - {}_1W_{2,cyl}$

$= 4 \times 3447.8 + 2 \times 2843.7 - 6 \times 2874.2 - 1085.84 =$ **1147.6 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.131

Consider the heat engine in Problem 8.111. The exit temperature was given as 800 K, but what are the theoretical limits for this temperature? Find the lowest and the highest, assuming the heat transfers are as given. For each case give the first and second law efficiency.

The **lowest exhaust temperature** will occur when the maximum amount of work is delivered which is a reversible process. Assume no other heat transfers then

Energy Eq.: $0 = h_i + q_{1500} - q_{750} - h_e - w$

Entropy Eq.: $0 = s_i + q_H/T_H + \cancel{0} - s_e - q_m/T_m$

$$s_e - s_i = q_H/T_H - q_m/T_m = s^\circ_{Te} - s^\circ_{Ti} - R \ln(P_e/P_i)$$

$$s^\circ_{Te} = s^\circ_{Ti} + R \ln(P_e/P_i) + q_H/T_H - q_m/T_m$$

$$= 6.86926 + 0.287 \ln(100/100) + 1200/1500 - 300/750$$

$$= 7.26926 \text{ kJ/kg K}$$

Table A.7.1 $\Rightarrow$ $T_{e,min} = \mathbf{446\ K}$, $h_e = 447.9$ kJ/kg

$$w_{rev} = h_i + q_{1500} - q_{750} - h_e = 300.47 + 1200 - 300 - 447.9$$

$$= 752.57 \text{ kJ/kg}$$

$$\eta_I = \eta_{TH} = \frac{w_{rev}}{q_{1500}} = \frac{752.57}{1200} = \mathbf{0.627}$$

The second law efficiency measures the work relative to the source of exergy and not q_{1500}. So

$$\eta_{II} = \frac{w_{rev}}{(1 - T_o/T_H)q_{1500}} = \frac{752.57}{(1 - 300/1500)1200} = \frac{752.57}{960} = \mathbf{0.784}$$

Comment: This measure places zero value of the loss at 750 K, zero exergy value for the two flow terms.

The **maximum exhaust temperature** occurs with no work out

$$h_e = h_i + q_H - q_m \quad \Rightarrow \quad h_e = 300.473 + 1200 - 300 = 1200.5 \text{ kJ/kg}$$

Table A.7.1 $\Rightarrow$ $T_{e,max} = \mathbf{1134\ K}$

Now : $w_{ac} = 0$ so $\eta_I = \eta_{II} = \mathbf{0}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.132

A small air gun has 1 cm^3 air at 250 kPa, 27°C. The piston is a bullet of mass 20 g. What is the potential highest velocity with which the bullet can leave?

Solution:
The exergy of the air can give the bullet kinetic energy expressed in the exergy change Eq.8.28 (no heat transfer and reversible),

$$\Phi_2 - \Phi_1 = m(u_2 - u_1) + P_o(V_2 - V_1) - mT_o(s_2 - s_1) = -{}_1W_2 + P_o(V_2 - V_1)$$

Ideal gas so: $m = PV/RT = \dfrac{250 \times 1 \times 10^{-6}}{0.287 \times 300} = 2.9 \times 10^{-6}$ kg

The second state with the lowest exergy to give maximum velocity is the dead state and we take $T_o = 20^oC$. Now solve for the exergy change

$$\Phi_2 - \Phi_1 = -m(u_2 - u_1) + mT_o(s_2 - s_1)$$

$$= mC_v(T_1 - T_2) + mT_o \left[C_p \ln(\frac{T_2}{T_1}) - R \ln(\frac{P_2}{P_1}) \right]$$

$$= 2.9 \times 10^{-6} [\ 0.717(27 - 20) + 293.15\ (1.004 \ln\frac{293}{300} - 0.287 \ln\frac{100}{250})]$$

$$= 0.0002180 \text{ kJ} = 0.218 \text{ J} = \tfrac{1}{2} m_{bullet} \mathbf{V}_{ex}^2$$

$$\mathbf{V}_{ex} = \sqrt{2 \times 0.218/0.020} = \mathbf{4.67\ m/s}$$

Comment: Notice that an isentropic expansion from 250 kPa to 100 kPa will give the final air temperature as 230.9 K but less work out. The above process is not adiabatic but Q is transferred from ambient at T_o.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.133

Consider the nozzle in Problem 7.154. What is the second law efficiency for the nozzle?

A nozzle in a high pressure liquid water sprayer has an area of 0.5 cm^2. It receives water at 350 kPa, 20°C and the exit pressure is 100 kPa. Neglect the inlet kinetic energy and assume a nozzle isentropic efficiency of 85%. Find the ideal nozzle exit velocity and the actual nozzle mass flow rate.

Solution:

C.V. Nozzle. Liquid water is incompressible v ≈ constant, no work, no heat transfer => Bernoulli Eq.7.17

$$\tfrac{1}{2}\mathbf{V}_{ex}^2 - 0 = v(P_i - P_e) = 0.001002\ (350 - 100) = 0.2505 \text{ kJ/kg}$$

$$\mathbf{V}_{ex} = \sqrt{2 \times 0.2505 \times 1000 \text{ J/kg}} = 22.38 \text{ m s}^{-1}$$

This was the ideal nozzle now we can do the actual nozzle, Eq. 7.30

$$\tfrac{1}{2}\mathbf{V}_{ex\ ac}^2 = \eta\ \tfrac{1}{2}\mathbf{V}_{ex}^2 = 0.85 \times 0.2505 = 0.2129 \text{ kJ/kg}$$

The second law efficiency is the actual nozzle compared to a reversible process between the inlet and actual exit state. However no work so the reversible exit state (with P_e, $T_{ex\ ac}$) then must have the reversible possible kinetic energy.

Energy actual nozzle: $h_i + 0 = h_e + \tfrac{1}{2}\mathbf{V}_{ex\ ac}^2$ same Z, no q and no w.

The reversible process has zero change in exergies from Eq.8.38 as

$$\psi_i = \psi_e = h_i + 0 - T_o\, s_i = h_e + \tfrac{1}{2}\mathbf{V}_{ex\ rev}^2 - T_o s_e$$

$$\tfrac{1}{2}\mathbf{V}_{ex\ rev}^2 = h_i - h_e + T_o\,(s_e - s_i) = \tfrac{1}{2}\mathbf{V}_{ex\ ac}^2 + T_o\, s_{gen}$$

We can not get properties for these states accurately enough by interpolation so use constant specific heat and incompressibility.

$$h_{ex\ ac} = h_i - \tfrac{1}{2}\mathbf{V}_{ex\ ac}^2 = u_{ex\ ac} + P_e v = u_i + P_i v - \tfrac{1}{2}\mathbf{V}_{ex\ ac}^2$$

$$u_{ex\ ac} - u_i = P_i v - P_e v - \tfrac{1}{2}\mathbf{V}_{ex\ ac}^2 = C(T_{ex\ ac} - T_i)$$

$$T_{ex\ ac} = T_i + (P_i v - P_e v - \tfrac{1}{2}\mathbf{V}_{ex\ ac}^2)/C$$

$$= 20 + [(350 - 100)\ 0.001002 - 0.2129] / 4.18 = 20.01°C$$

$$\tfrac{1}{2}\mathbf{V}_{ex\ rev}^2 = \tfrac{1}{2}\mathbf{V}_{ex\ ac}^2 + T_o\, s_{gen} = 0.2129 + 293.15 \times 4.18 \ln \frac{293.16}{293.15}$$

$$= 0.2547 \text{ kJ/kg}$$

$$\eta_{II} = 0.2129/0.2547 = \mathbf{0.84}$$

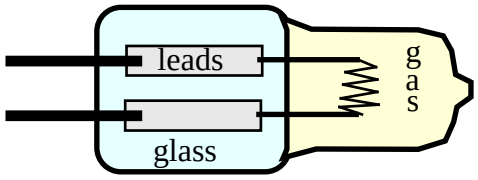
8.134

Consider the light bulb in Problem 6.189. What are the fluxes of exergy at the various locations mentioned? What are the exergy destruction in the filament, the entire bulb including the glass and the entire room including the bulb? The light does not affect the gas or the glass in the bulb but it gets absorbed on the room walls.

A small halogen light bulb receives an electrical power of 50 W. The small filament is at 1000 K and gives out 20% of the power as light and the rest as heat transfer to the gas, which is at 500 K; the glass is at 400 K. All the power is absorbed by the room walls at 25°C. Find the rate of generation of entropy in the filament, in the total bulb including glass and the total room including bulb.

Solution:



$\dot{W}_{el} = 50$ W

$\dot{Q}_{RAD} = 10$ W

$\dot{Q}_{COND} = 40$ W

We will assume steady state and no storage in the bulb, air or room walls.

C.V. Filament steady-state

Energy Eq.3.3: $dE_{c.v.}/dt = 0 = \dot{W}_{el} - \dot{Q}_{RAD} - \dot{Q}_{COND}$

Entropy Eq.6.42: $dS_{c.v.}/dt = 0 = -\dfrac{\dot{Q}_{RAD}}{T_{FILA}} - \dfrac{\dot{Q}_{COND}}{T_{FILA}} + \dot{S}_{gen}$

$$\dot{I} = T_o \dot{S}_{gen} = (\dot{Q}_{RAD} + \dot{Q}_{COND}) \frac{T_o}{T_{FILA}} = T_o \frac{\dot{W}_{el}}{T_{FILA}} = 298 \frac{50}{1000} = \mathbf{14.9\ W}$$

C.V. Bulb including glass

$\dot{Q}_{RAD}$ leaves at 1000 K $\dot{Q}_{COND}$ leaves at 400 K

$$\dot{I} = T_o \dot{S}_{gen} = T_o \int d\dot{Q}/T = 298[-(-10/1000) - (-40/400)] = \mathbf{32.8\ W}$$

C.V. Total room. All energy leaves at 25°C

Eq.3.3: $dE_{c.v.}/dt = 0 = \dot{W}_{el} - \dot{Q}_{RAD} - \dot{Q}_{COND}$

Eq.6.42: $dS_{c.v.}/dt = 0 = -\dfrac{\dot{Q}_{TOT}}{T_{WALL}} + \dot{S}_{gen}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$\dot{I} = T_o \dot{S}_{gen} = T_o \frac{\dot{Q}_{TOT}}{T_{WALL}} = 298 \frac{50}{25+273} = \mathbf{50\ W}$$

Since the room is at T_o then all the incoming exergy is destroyed.

Flux into filament: Flux = $\dot{W}_{el}$ = **50 W**

Flux leaving the filament: $\text{Flux} = (\dot{Q}_{RAD} + \dot{Q}_{COND})(1 - \frac{T_o}{T_{FILA}})$

$$= 50\ \text{W} - 14.9\ \text{W} = \mathbf{35.1\ W}$$

Flux leaving the glass: $\text{Flux} = \dot{Q}_{RAD}(1 - \frac{T_o}{T_{FILA}}) + \dot{Q}_{COND}(1 - \frac{T_o}{T_{glass}})$

$$= 10 \times (1 - \frac{298}{1000}) \text{ W} + 40 \times (1 - \frac{298}{400}) \text{ W}$$

$$= 7.02\ \text{W} + 10.2\ \text{W} = \mathbf{17.22\ W}$$

Flux at walls: Flux = 0 (wall is at T_o)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.135

Air in a piston/cylinder arrangement, shown in Fig. P8.135, is at 200 kPa, 300 K with a volume of 0.5 m^3. If the piston is at the stops, the volume is 1 m^3 and a pressure of 400 kPa is required. The air is then heated from the initial state to 1500 K by a 1700 K reservoir. Find the total irreversibility in the process assuming surroundings are at 20°C.

Solution:

Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Entropy Eq,: $m(s_2 - s_1) = \int dQ/T + {}_1S_{2\ gen}$

Process: $P = P_0 + \alpha(V-V_0)$ if $V \le V_{stop}$

Information: $P_{stop} = P_0 + \alpha(V_{stop}-V_0)$

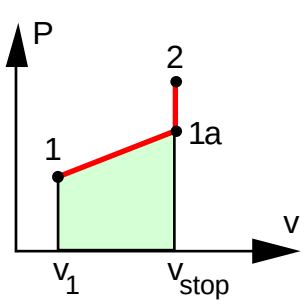
Eq. of state $\Rightarrow$ $T_{stop} = T_1P_{stop}V_{stop}/P_1V_1 = 1200 < T_2$

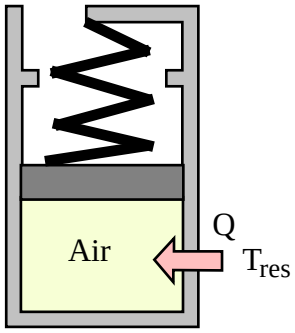
So the piston will hit the stops => $V_2 = V_{stop}$

$$P_2 = (T_2/T_{stop})\, P_{stop} = (1500/1200)\, 400 = 500 \text{ kPa} = 2.5\, P_1$$

State 1:

$$m_2 = m_1 = \frac{P_1V_1}{RT_1} = \frac{200 \times 0.5}{0.287 \times 300} = 1.161 \text{ kg}$$





$${}_1W_2 = \tfrac{1}{2}(P_1 + P_{stop})(V_{stop} - V_1) = \tfrac{1}{2}(200 + 400)(1 - 0.5) = 150 \text{ kJ}$$

$${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = 1.161(1205.25 - 214.36) + 150 = 1301 \text{ kJ}$$

$$s_2 - s_1 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1) = 8.6121 - 6.8693 - 0.287 \ln 2.5 = 1.48 \text{ kJ/kg K}$$

Take control volume as total out to reservoir at T_{RES}

$${}_1S_{2\ gen\ tot} = m(s_2 - s_2) - {}_1Q_2/T_{RES} = 1.161 \times 1.48 - 1301/1700 = 0.953 \text{ kJ/K}$$

$${}_1I_2 = T_0({}_1S_{2\ gen}) = 293.15 \times 0.953 = \mathbf{279\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.136

Air enters a steady-flow turbine at 1600 K and exhausts to the atmosphere at 1000 K. The second law efficiency is 85%. What is the turbine inlet pressure?

C.V.: Turbine, exits to atmosphere so assume P_e = 100 kPa

Inlet: T_i = 1600 K, Table A.7: h_i = 1757.3 kJ/kg, s_i^o = 8. 69051 kJ/kg K

Exit: T_e = 1000 K, h_e = 1046.2 kJ/kg, s_e^o = 8. 13493 kJ/kg K

Energy Eq.: $q + h_i = h_e + w$; $q = 0$ => $w = (h_i - h_e) = 711.1$ kJ/kg

Second law efficiency expresses work as a fraction of exergy change

$\psi_i - \psi_e = w/\eta_{II} = 711.11/0.85 = 836.6$ kJ/kg $= (h_i - h_e) - T_o(s_i - s_e)$

$h_i - h_e = w = 711.11$ kJ/kg, assume $T_o = 25^oC$ →

$s_i - s_e = (711.11 - 836.6) / 298.15 = -0.420896$ kJ/kg-K

$s_i - s_e = s_i^o - s_e^o - R \ln(P_i/P_e) = -0.4209$ kJ/kg K

=> $R \ln(P_i/P_e) = 8.69051 - 8.13493 + 0.420896 = 0.976476$ kJ/kg-K

$P_i/P_e = 30.035$; P_i = **3003 kPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.137

A 1 kg rigid steel tank contains 1.2 kg of R-134a at 20°C and 500 kPa. Now the set-up is placed in a freezer that brings it to -20°C. The freezer operates in a 20°C kitchen and has a coefficient of performance that is half that of a Carnot refrigerator. Find the heat transfer out of the R-134a, the extra work input to the refrigerator due to this process and the total irreversibility including the refrigerator.

C.V. The R-134a and the steel.

Energy Eq.: $m_R(u_2 - u_1)_R + m_{st}(u_2 - u_1)_{st} = {}_1Q_2 - {}_1W_2$

Entropy Eq,: $m_R(s_2 - s_1)_R + m_{st}(s_2 - s_1)_{st} = \int dQ/T + {}_1S_{2\,gen}$

Process: $V = C$ so ${}_1W_2 = 0$

State 1: $v_1 = 0.04226\ m^3/kg$, $u_1 = 390.52\ kJ/kg$, $s_1 = 1.7342\ kJ/kg\text{-}K$

State 2: $v_2 = v_1$, -20°C => 2 phase state

$x_2 = (v_2 - v_f)/v_{fg} = (0.04226 - 0.000738)/0.14576 = 0.28486$

$u_2 = 173.65 + x_2 \times 192.85 = 228.59\ kJ/kg$,

$s_2 = 0.9007 + x_2 \times 0.8388 = 1.13964\ kJ/kg\text{-}K$

${}_1Q_2 = m_R(u_2 - u_1)_R + m_{st}(u_2 - u_1)_{st}$

$= 1.2\ (228.59 - 390.52) + 1 \times 0.46(-20 - 20) =$ **–212.7 kJ**

Refrigerator: $\beta = 0.5\ \beta_{Carnot} = 0.5\ \dfrac{T_L}{T_H - T_L} = 0.5\ \dfrac{253.15}{20 - (-20)} = 3.164$

$W_{ref} = Q_L/\beta = 212.7\ kJ/\ 3.164 =$ **67.23 kJ**

C.V. Total incl. refrigerator. Storage effect in R-134a and steel, otherwise transfer terms.

Energy Eq.: $m_R(u_2 - u_1)_R + m_{st}(u_2 - u_1)_{st} = W_{ref} - Q_H$

Entropy Eq,: $m_R(s_2 - s_1)_R + m_{st}(s_2 - s_1)_{st} = -Q_H/T_0 + {}_1S_{2\,gen}$

$Q_H = W_{ref} - m(u_2 - u_1) = 67.23 - (-212.7) = 279.93\ kJ$

$${}_1S_{2\,gen} = m_R(s_2 - s_1)_R + m_{st}(s_2 - s_1)_{st} + \frac{Q_H}{T_0}$$

$$= 1.2(1.13964\text{-}1.7342) + 1 \times 0.46\ \ln\left(\frac{253.15}{293.15}\right) + \frac{279.93}{293.15}$$

$= -0.713472 - 0.06748 + 0.954904 = 0.17395\ kJ/K$

${}_1I_2 = T_0\ ({}_1S_{2\,gen}) = 293.15 \times 0.17395 =$ **50.99 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.138

A piston/cylinder arrangement has a load on the piston so it maintains constant pressure. It contains 1 kg of steam at 500 kPa, 50% quality. Heat from a reservoir at 700°C brings the steam to 600°C. Find the second-law efficiency for this process. Note that no formula is given for this particular case so determine a reasonable expression for it.

Solution:

1: Table B.1.2 $P_1, x_1 \Rightarrow v_1 = 0.001093 + 0.5\times0.3738 = 0.188\ m^3/kg,$

$h_1 = 640.21 + 0.5\times2108.47 = 1694.5\ kJ/kg,$

$s_1 = 1.8606 + 0.5\times4.9606 = 4.341\ kJ/kg\ K$

2: $P_2 = P_1, T_2 \Rightarrow v_2 = 0.8041,\ h_2 = 3701.7\ kJ/kg,\ s_2 = 8.3521\ kJ/kg\ K$

Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2 = {}_1Q_2 - P(V_2 - V_1)$

${}_1Q_2 = m(u_2 - u_1) + Pm(v_2 - v_1) = m(h_2 - h_1) = 2007.2\ kJ$

${}_1W_2 = Pm(v_2 - v_1) = 308.05\ kJ$

${}_1W_{2\ to\ atm} = P_0m(v_2 - v_1) = 61.61\ kJ$

Useful work out $= {}_1W_2 - {}_1W_{2\ to\ atm} = 246.44\ kJ$

$$\Delta\phi_{reservoir} = (1 - T_0/T_{res})_1Q_2 = \left(1 - \frac{298.15}{973.15}\right) 2007.2 = 1392.2\ kJ$$

$\eta_{II} = W_{net}/\Delta\phi =$ **0.177**

Remark: You could argue that the stored exergy (exergy) should be accounted for in the second law efficiency, but it is not available from this device alone.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.139

A jet of air at 200 m/s flows at 25°C, 100 kPa towards a wall where the jet flow stagnates and leaves at very low velocity. Consider the process to be adiabatic and reversible. Use the exergy equation and the second law to find the stagnation temperature and pressure.

Solution:

C.V. From free flow to stagnation point. Reversible adiabatic steady flow.

Exergy Eq.8.38: $0 = \dot{m}\psi_i - \dot{m}\psi_e - \dot{\Phi}_{destr.}$

Entropy Eq.: $0 = \dot{m}s_i - \dot{m}s_e + \int \dot{m}dq/T + \dot{m}s_{gen} = \dot{m}s_i - \dot{m}s_e + 0 + 0$

Process: Reversible $\dot{\Phi}_{destr.} = 0$, $s_{gen} = 0$, adiabatic $q = 0$

From exergy Eq.: $\psi_e - \psi_i = 0 = h_e - T_o s_e - h_i + T_o s_i - \frac{1}{2}V_i^2$

From entropy Eq.: $s_e = s_i$, so entropy terms drop out

Exergy eq. now leads to: $h_e = h_i + \frac{1}{2}V_i^2 \Rightarrow T_e = T_i + \frac{1}{2}V_i^2 / C_p$

$$T_e = 25 + \frac{1}{2}\frac{200^2 \text{ J/kg}}{1004 \text{ J/kg K}} = \mathbf{44.92^oC}$$

Eq.8.23: $P_e = P_i (T_e/T_e)^{\frac{k}{k-1}} = 100 \left(\frac{273 + 44.92}{273 + 25}\right)^{1.4 / 0.4} = \mathbf{125.4\ kPa}$

State i is the free stream state.

State e is the stagnation state.

Problems Solved Using Pr and vr Functions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.43 Solved using the isentropic P_r function in A.7.2

An air compressor receives atmospheric air at $T_0 = 17°C$, 100 kPa, and compresses it up to 1400 kPa. The compressor has an isentropic efficiency of 88% and it loses energy by heat transfer to the atmosphere as 10% of the isentropic work. Find the actual exit temperature and the reversible work.

C.V. Compressor

Isentropic: $w_{c,in,s} = h_{e,s} - h_i$; $s_{e,s} = s_i$

Table A.7: $P_{r,e,s} = P_{r,i} \times (P_e/P_i) = 0.9917 \times 14 = 13.884$

$\Rightarrow h_{e,s} = 617.51$ kJ/kg

$w_{c,in,s} = 617.51 - 290.58 = 326.93$ kJ/kg

Actual: $w_{c,in,ac} = w_{c,in,s}/\eta_c = 371.51$; $q_{loss} = 32.693$ kJ/kg

$w_{c,in,ac} + h_i = h_{e,ac} + q_{loss}$

$\Rightarrow h_{e,ac} = 290.58 + 371.51 - 32.693 = 629.4$ kJ/kg

$\Rightarrow T_{e,ac} = 621$ K

Reversible: $w^{rev} = h_i - h_{e,ac} + T_0(s_{e,ac} - s_i)$

$= 290.58 - 629.4 + 290.15 \times (7.6121 - 6.8357)$

$= -338.82 + 225.42 =$ **-113.4 kJ/kg**

Since q_{loss} is also to the atmosphere the above term is the net heat transfer and the reversible work requires the heat transfer to be reversible.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.69 Solved using the isentropic P_r function in A.7.2

An air compressor is used to charge an initially empty 200-L tank with air up to 5 MPa. The air inlet to the compressor is at 100 kPa, 17°C and the compressor isentropic efficiency is 80%. Find the total compressor work and the change in exergy of the air.

Solution:

C.V. Tank + compressor Transient process with constant inlet conditions, no heat transfer.

Continuity: $m_2 - m_1 = m_{in}$ ($m_1 = 0$) Energy: $m_2u_2 = m_{in}h_{in} - {}_1W_2$

Entropy: $m_2s_2 = m_{in}s_{in} + {}_1S_{2\,gen}$

Reversible compressor: ${}_1S_{2\,GEN} = 0 \Rightarrow s_2 = s_{in}$

State 1: $v_1 = RT_1/P_1 = 0.8323\ m^3/kg$,

State inlet, Table A.7.1: $h_{in} = 290.43$ kJ/kg, $s^o_{Tin} = 6.8352$ kJ/kg K

Table A.7.2 $P_{rin} = 0.9899$ used for constant s process

Table A.7.2 $\Rightarrow$ $P_{r2} = P_{rin}(P_2/P_{in}) = 0.9899 \times (5000/100) = 49.495$

$\Rightarrow$ $T_{2,s} = 855$ K, $u_{2,s} = 637.2$ kJ/kg

$\Rightarrow$ ${}_1w_{2,s} = h_{in} - u_{2,s} = 290.43 - 637.2 = -346.77$ kJ/kg

Actual compressor: ${}_1w_{2,AC} = {}_1w_{2,s}/\eta_c = -433.46$ kJ/kg

$u_{2,AC} = h_{in} - {}_1w_{2,AC} = 290.43 - (-433.46) = 723.89$ kJ/kg

Backinterpolate in Table A.7.1 $\Rightarrow$ $T_{2,AC} = 958$ K, $s^o_{T2,AC} = 8.0867$ kJ/kg K

$\Rightarrow$ $v_2 = RT_2/P_2 = 0.055\ m^3/kg$

State 2 $\boxed{u, P}$ $m_2 = V_2/v_2 = 3.636$ kg $\Rightarrow$ ${}_1W_2 = m_2({}_1w_{2,AC}) =$ **-1576 kJ**

$m_2(\phi_2 - \phi_1) = m_2[u_2 - u_1 + P_0(v_2 - v_1) - T_0(s_2 - s_1)]$

$= 3.636\ [723.89 - 207.19 + 100(0.055 - 0.8323) - 290[8.0867 - 6.8352 - 0.287 \ln(5000/100)]$ = **1460.3 kJ**

Here we used Eq.6.19 for the change in entropy.

8.140E

A control mass gives out 1000 Btu of energy in the form of

a. Electrical work from a battery
b. Mechanical work from a spring
c. Heat transfer at 700 F

Find the change in exergy of the control mass for each of the three cases.

Solution:

a) Work is exergy $\Delta\Phi = -W_{el} = -$**1000 Btu**

b) Work is exergy $\Delta\Phi = -W_{spring} = -$**1000 Btu**

c) Give the heat transfer to a Carnot heat engine and W is exergy

$$\Delta\Phi = -\left(1 - \frac{T_0}{T_H}\right) Q_{out} = -\left(1 - \frac{537}{1160}\right) 1000 \text{ Btu} = -\mathbf{537\ Btu}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.141E

A fraction of some power to a motor (1), 2 kW, is turned into heat transfer at 800 R (2) and then it dissipates in the ambient at 540 R (3). Give the rates of exergy along the process 1-2-3.

Solution:

The exergy of an amount of heat transfer equals the possible work that can be extracted. This is the work out of a Carnot heat engine with heat transfer to the ambient as the other reservoir. The result is from Chapter 5 as also shown in Eq. 8.1 and Eq. 8.38

1: $\dot{\Phi} = \dot{W} =$ **2 kW = 1.896 Btu/s**

2: $\dot{\Phi} = \dot{W}_{rev\ HE} = (1 - \frac{T_o}{T})\dot{Q} = (1 - \frac{540}{800})\ 2\ kW =$ **0.65 kW = 0.616 Btu/s**

3: $\dot{\Phi} = \dot{W}_{rev\ HE} = (1 - \frac{T_o}{T_o})\dot{Q} = (1 - \frac{540}{540})\ 2\ kW =$ **0 kW = 0 Btu/s**

As the energy transforms from wotrk to heat transfer it loses exergy and as the heat transfer goes to lower and lower T its exergy value drops ending as zero at the ambient T.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.142E

A refrigerator should remove 1.5 Btu/s from the cold space at 15 F while it rejects heat to the kitchen at 77 F. Find the reversible work.

The reversible work is related to the Carnot cycle work as the the two reservoirs are at constant temperatures.

$$\dot{W} = \dot{Q}_L / \beta \; ; \qquad \beta = \dot{Q}_L / \dot{W}_{carnot} = \frac{T_L}{T_H - T_L} = \frac{15 + 459.7}{77 - 15} = 7.65$$

In general we have defined the reversible work with the standard sign definition

$$\dot{W}^{rev} = - \dot{Q}_L / \beta = - \frac{1.5}{7.65} \text{ Btu/s} = \mathbf{-0.2\ Btu/s}$$

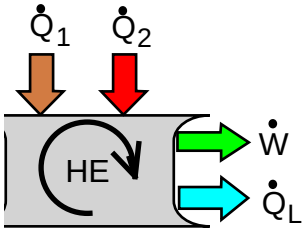
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.143E

A heat engine receives 15 000 btu/h at 1400 R and 30 000 btu/h at 1800 R rejecting energy by heat transfer at 900 R. Assume it is reversible and find the power output. How much power could be produced if it could reject energy at T_o = 540 R?

Solution:

C.V. The heat engine, this is in steady state.



Energy Eq.: $0 = \dot{Q}_1 + \dot{Q}_2 - \dot{Q}_L - \dot{W}$

Entropy Eq.: $0 = \dfrac{\dot{Q}_1}{T_1} + \dfrac{\dot{Q}_2}{T_2} - \dfrac{\dot{Q}_L}{T_L} + 0$

Now solve for $\dot{Q}_L$ from the entropy equation

$$\dot{Q}_L = \frac{T_L}{T_1}\dot{Q}_1 + \frac{T_L}{T_2}\dot{Q}_2 = \frac{900}{1400} \times 15\,000 + \frac{900}{1800} \times 30\,000 = 24\,643 \text{ Btu/h}$$

Substitue into the enrgy equation and solve for the work term

$$\dot{W} = \dot{Q}_1 + \dot{Q}_2 - \dot{Q}_L = 15\,000 + 30\,000 - 24\,643 = \mathbf{20\,357\ Btu/h}$$

For a low temperature of 540 R we can get

$$\dot{Q}_{L2} = \frac{540}{900}\dot{Q}_L = 14\,786 \text{ btu/h}$$

$$\dot{W} = \dot{Q}_1 + \dot{Q}_2 - \dot{Q}_L = 15\,000 + 30\,000 - 14\,786 = \mathbf{30\,214\ Btu/h}$$

Remark: Notice the large increase in the power output.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

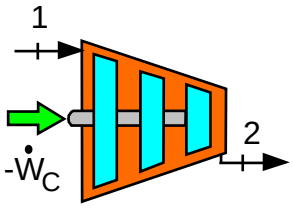
8.144E

The compressor in a refrigerator takes refrigerant R-134a in at 15 lbf/in.^{2}, 0 F and compresses it to 125 lbf/in.^{2}, 100 F. With the room at 70 F find the reversible heat transfer and the minimum compressor work.

Solution:

C.V. Compressor out to ambient. Minimum work in is the reversible work.

Steady flow, 1 inlet and 2 exit



Energy Eq.: $w_c = h_1 - h_2 + q^{rev}$

Entropy Eq.: $s_2 = s_1 + \int dq/T + s_{gen} = s_1 + q^{rev}/T_o + 0$

$$=> \quad q^{rev} = T_o(s_2 - s_1)$$

q^{rev} = 529.67 R × (0.41262 – 0.42288) Btu/lbm-R = **-5.43 Btu/lbm**

$w_{c\,min} = h_1 - h_2 + T_o(s_2 - s_1)$ = 167.193 – 181.059 – 5.43 = **–19.3 Btu/lbm**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.145E

A compressor in a refrigerator receives R-410A at 20 psia, -40 F and it brings it up to 100 psia, using an actual specific work of 23.48 Btu/lbm in an adiabatic compression. Find the specific reversible work.

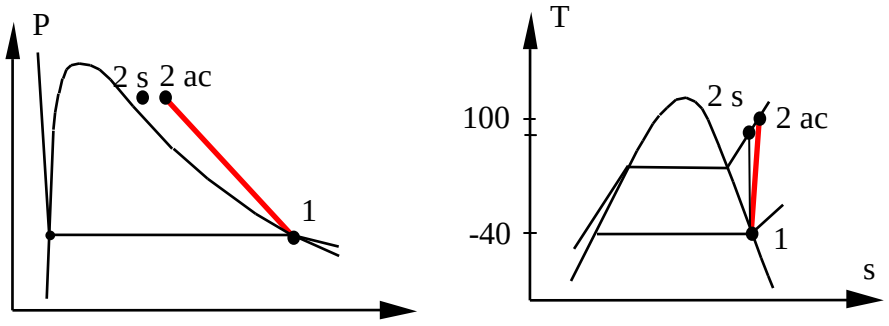
Energy Eq.: $0 = h_1 - h_2 - w$

State 1: F.9.2 $h_1 = 113.73$ Btu/lbm, $s_1 = 0.2772$ Btu/lbm-R

$h_2 = h_1 - w = 113.73 + 23.48 = 137.21$ kJ/kg

State 2: F.9.2 P, $h_2 = 137.21$ Btu/lbm, $T_2 = 100$ F, $s_2 = 0.2840$ Btu/lbm-R

$$w^{rev} = \psi_1 - \psi_2 = h_1 - h_2 - T_0 (s_1 - s_2)$$
$$= 113.73 - 137.21 - 536.7 (0.2772 - 0.2840)$$
$$= -23.48 + 3.65 = \mathbf{-19.83\ Btu/lbm}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.146E

Air flows through a constant pressure heating device as shown in Fig. P8.27. It is heated up in a reversible process with a work input of 85 Btu/lbm air flowing. The device exchanges heat with the ambient at 540 R. The air enters at 540 R, 60 lbf/in.^{2}. Assuming constant specific heat develop an expression for the exit temperature and solve for it.

C.V. Total out to T_0

Energy Eq.: $h_1 + q_0^{rev} - w^{rev} = h_2$

Entropy Eq.: $s_1 + q_0^{rev}/T_0 = s_2 \quad \Rightarrow \quad q_0^{rev} = T_0(s_2 - s_1)$

$h_2 - h_1 = T_0(s_2 - s_1) - w^{rev}$ (same as from Eq. 8.14)

Constant C_p gives: $C_p(T_2 - T_1) = T_0 C_p \ln (T_2/T_1) + 85$

The energy equation becomes

$$\mathbf{T_2 - T_0 \ln(T_2/T_1) = T_1 + 85/C_p}$$

$T_1 = 540$ R, $C_p = 0.24$ Btu/lbm R, $T_0 = 540$ R

$T_2 - 540 \ln (T_2/540) = 540 + (85/0.24) = 894.17$ R

Now trial and error on T_2

At 1400 R LHS = 885.56 R(too low)

At 1420 R LHS = 897.9 R

Interpolate to get $\mathbf{T_2 = 1414\ R}$ (LHS = 894.19 R **OK**)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.147E

An adiabatic and reversible air compressor takes air in at 15 psia, 560 R. The air exits at 90 psia at the rate of 0.8 lbm/s. Determine the minimum compressor work input and repeat for an inlet at 530 R instead. Why is the work less for a lower inlet *T*?

Compressor. Reversible adiabatic, constant s:

Inlet at 560 R: $$T_{2S} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 560\ \text{R}\ \left(\frac{90}{15}\right)^{0.2857} = 934.3\ \text{R}$$

The reversible process ensures the minimum work input.

$$\dot{W} = \dot{m}(-w_S) = \dot{m}C_{P0}(T_{2S} - T_1) = 0.8 \times 0.24\ (934.3 - 560)$$
$$= \mathbf{71.86\ Btu/s}$$

Inlet at 530 R: $$T_{2S} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 530\ \text{R}\ \left(\frac{90}{15}\right)^{0.2857} = 884.3\ \text{R}$$

$$\dot{W} = \dot{m}(-w_S) = \dot{m}C_{P0}(T_{2S} - T_1) = 0.8 \times 0.24\ (884.3 - 530)$$
$$= \mathbf{68.0\ Btu/s}$$

The work term is reduced due to the reduced specific volume, v_1, recall Eq. 7.15 for the indicated shaft work.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.148E

A rock bed consists of 12 000 lbm granite and is at 160 F. A small house with lumped mass of 24 000 lbm wood and 2000 lbm iron is at 60 F. They are now brought to a uniform final temperature with no external heat transfer by connecting the house and rock bed through some heat engines. If the process is reversible, find the final temperature and the work done during the process.

Take C.V. Total (rockbed and heat engine)

Energy Eq.: $m_{rock}(u_2 - u_1) + m_{wood}(u_2 - u_1) + m_{Fe}(u_2 - u_1) = -{}_1W_2$

Entropy Eq.: $m_{rock}(s_2 - s_1) + m_{wood}(s_2 - s_1) + m_{Fe}(s_2 - s_1) = 0$

$$(mC)_{rock} \ln \frac{T_2}{T_1} + (mC)_{wood} \ln \frac{T_2}{T_1} + (mC)_{Fe} \ln \frac{T_2}{T_1} = 0$$

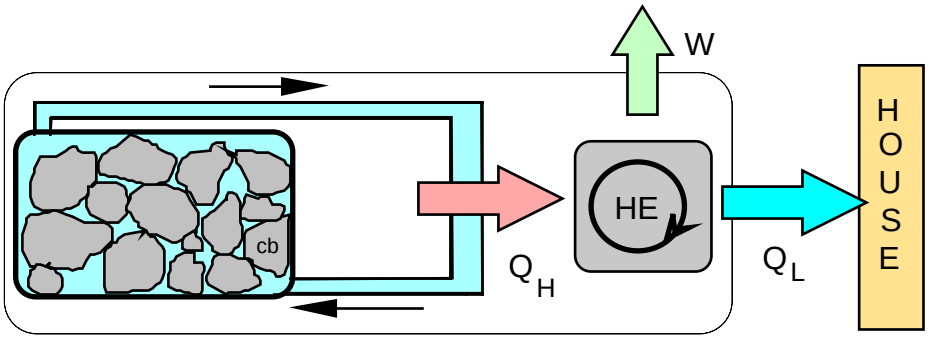
$$12000 \times 0.212 \ln (T_2/619.67) + 24000 \times 0.33 \ln (T_2/519.67)$$
$$+ 2000 \times 0.11 \ln (T_2/519.67) = 0$$

$\Rightarrow$ **T_2 = 541.9 R**

Now from the energy equation

$$-{}_1W_2 = 12\,000 \times 0.212(541.9 - 619.67)$$
$$+ (24\,000 \times 0.33 + 2000 \times 0.11)(541.9 - 519.67)$$

$\Rightarrow$ ${}_1W_2$ = **16 895 Btu**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.149E

A basement is flooded with 250 ft^3 of water at 60 F. It is pumped out with a small pump driven by a 0.75 kW electric motor. The hose can reach 25 ft vertically up and to ensure the water can flow over the edge of a dike it should have a velocity of 45 ft/s at that point generated by a nozzle, see Fig. P8.34. Find the maximum flow rate you can get and how fast the basement can be emptied.

C.V. Pump plus hose and nozzle, single steady state flow. For maximum flow rate assume reversible process so from Eq.8.14:

$$w^{rev} = T_o\,(s_2 - s_1) - (h_{2\,tot} - h_{1\,tot}) + 0$$

Since we have no heat transfer and reversible s is constant and with a liquid flow T is also constant so $h_2 = h_1$. We could also have used Bernoulli equation.

$$w^{rev} = -\left(\frac{1}{2}V_2^2 + gH - 0\right) = -\left(\frac{1}{2}\,45^2/25\,037 + 1 \times 25/778\right)$$

$$= -(0.04044 + 0.032134) = -\,0.07257 \text{ Btu/lbm}$$

Recall 1 Btu/lbm = 25 037 ft^2/s^2 from conversion in Table A.1

$$\dot{m} = \dot{W}/\,(-w^{rev}) = \frac{(0.75/1.055)\text{ Btu/s}}{0.07257\text{ Btu/lbm}} = \mathbf{9.796\ lbm/s}$$

$$m = V/v = 250\ ft^3 / 0.01603\ ft^3/lbm = 15\,596\ lbm$$

$$\Delta t = m / \dot{m} = \frac{15\,596\text{ lbm}}{9.796\text{ lbm/s}} = 1592\text{ sec} = \mathbf{26.5\ min.}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

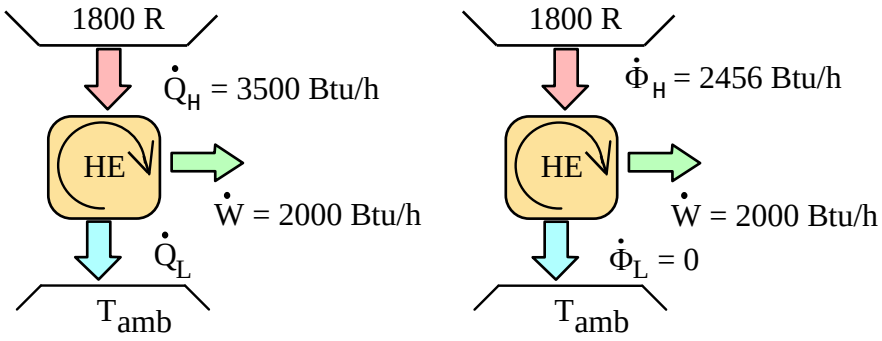
8.150E

A heat engine receives 3500 Btu/h heat transfer at 1800 R and gives out 2000 Btu/h as work with the rest as heat transfer to the ambient. What are the fluxes of exergy in and out?

Exergy flux in: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H = \left(1 - \frac{536.7}{1800}\right) 3500 \text{ Btu/h} =$ **2456 btu/h**

Exergy flux out: $\dot{\Phi}_L = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L =$ **0** $\quad (T_L = T_o)$

The other exergy flux out is the power $\dot{\Phi}_{out} = \dot{W} =$ **2000 Btu/h**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.151E

A flow of air at 150 psia, 540 R is throttled to 75 psia. What is the irreversibility? What is the drop in flow exergy assuming an ambient at 77 F?

A throttle process is constant enthalpy if we neglect kinetic energies.

Process: $h_e = h_i$ so ideal gas => $T_e = T_i$

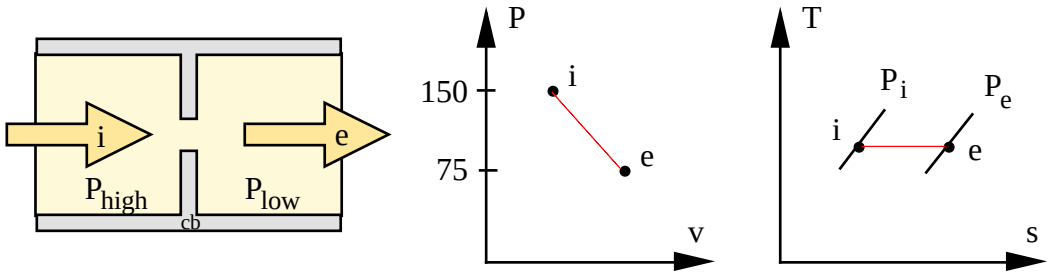
Entropy Eq.: $s_e - s_i = s_{gen} = s^o_{Te} - s^o_{Ti} - R \ln \frac{P_e}{P_i} = 0 - R \ln \frac{P_e}{P_i}$

$$s_{gen} = - \frac{53.34}{778} \ln \left(\frac{75}{150}\right) = 0.0475 \text{ Btu/lbm R}$$

Eq.8.15: $i = T_o \, s_{gen} = 536.7 \times 0.0475 =$ **25.49 Btu/lbm**

The drop in exergy is exergy destruction, which is the irreversibility

$$\Delta\psi = i = \textbf{25.49 Btu/lbm}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Irreversibility

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.152E

A compressor in a refrigerator receives R-410A at 20 psia, -40 F and it brings it up to 100 psia, 100 F in an adiabatic compression. Find the specific work, entropy generation and irreversibility.

States: 1: F.9.2 $h_1 = 113.73$ Btu/lbm, $s_1 = 0.2772$ Btu/lbm-R

2: F.9.2 $h_2 = 137.21$ Btu/lbm, $s_2 = 0.2840$ Btu/lbm-R

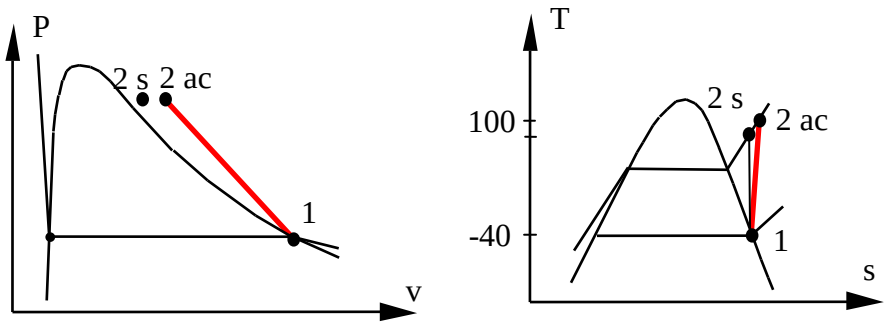
C.V. Compressor, steady state, q = 0, no KE, PE energies.

Energy Eq.: $w = h_1 - h_2 = 113.73 - 137.21 =$ **–23.48 Btu/lbm**

Entropy Eq.: $0 = s_1 - s_2 + s_{gen}$ ⇨

$$s_{gen} = s_2 - s_1 = 0.2840 - 0.2772 = \mathbf{0.0068\ Btu/lbm\text{-}R}$$

Irreversibility: $i = T_o\, s_{gen} = 536.7\ R \times 0.0068$ Btu/lbm-R = **3.65 Btu/lbm**



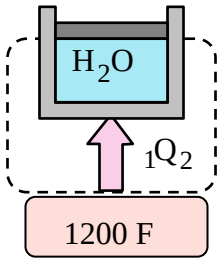
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.153E

A constant pressure piston/cylinder contains 4 lbm of water at 1000 psia and 200 F. Heat is added from a reservoir at 1200 F to the water until it reaches 1200 F. We want to find the total irreversibility in the process.

Solution:

C.V. Piston cylinder out to the reservoir (incl. the walls).



Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Entropy Eq.: $m(s_2 - s_1) = {}_1Q_2/T_{res} + {}_1S_{2\ gen}$

State 1: $h_1 = 168.07$ Btu/lbm, $s_1 = 0.294$ Btu/lbm R

State 2: $h_2 = 1619.67$ Btu/lbm, $s_2 = 1.726$ Btu/lbm R

Process: $P = C \Rightarrow {}_1W_2 = P(V_2 - V_1)$

From the energy equation we get

$${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = m(h_2 - h_1)$$

$$= 4(1619.67 - 168.07) = 5806.4 \text{ Btu}$$

From the entropy equation we get

$${}_1S_{2\ gen} = m(s_2 - s_1) - \frac{{}_1Q_2}{T_{res}} = 4(1.726 - 0.294) - \frac{5806.4}{459.7 + 1200}$$

$$= 2.2295 \text{ Btu/R}$$

Now the irreversibility is from Eq. 8.18

$${}_1I_2 = m\ {}_1i_2 = T_o\ {}_1S_{2\ gen} = 536.7 \text{ R} \times 2.2295 \text{ Btu/R} = \mathbf{1197\ Btu}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.154E

A constant "flow" of steel parts 4 lbm/s at 77 F goes into a furnace where they are heat treated to 1600 F by a source at an average 2100 R. Find the reversible work and the irreversibility in this process?

Energy Eq.: $0 = \dot{m}(h_i - h_e) + \dot{Q}$

Entropy Eq.: $0 = \dot{m}(s_i - s_e) + \dot{Q} / T_s + \dot{S}_{gen}$

$$\dot{Q} = \dot{m}(h_e - h_i) = \dot{m}C_P (T_e - T_i) = 4 \text{ lbm/s} \times 0.11 \text{ Btu/lbm-R} \times 1523 \text{ R}$$
$$= 670 \text{ Btu/s}$$

$$\dot{S}_{gen} = \dot{m}(s_e - s_i) - \dot{Q} / T_s = \dot{m}C_P \ln(T_e/T_i) - \dot{Q} / T_s$$
$$= 4 \text{ lbm/s} \times 0.11 \text{ Btu/lbm-R} \times \ln(2060/537)$$
$$- (670 / 2100) \text{ Btu/s-R}$$
$$= 0.2725 \text{ Btu/s-R}$$

$$\dot{I} = T_0 \dot{S}_{gen} = 537 \text{ R} \times 0.2725 \text{ Btu/s-R} = \mathbf{146.3 \text{ Btu/s}}$$

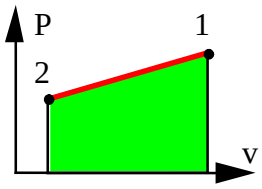
The reversible work is equal to the irreversibility plus the actual work, Eq.8.12

$$\dot{W}^{rev} = \dot{I} + \dot{W}_{ac} = \dot{I} = \mathbf{146.3 \text{ Btu/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.155E

A cylinder with a piston restrained by a linear spring contains 4 lbm of carbon dioxide at 70 psia, 750 F. It is cooled to 75 F, at which point the pressure is 45 psia. Find the reversible work and the irreversibility assuming the heat transfer is with surroundings at 68 F.



Linear spring gives

$$ {}_1W_2 = \int PdV = \tfrac{1}{2}(P_1 + P_2)(V_2 - V_1) $$

$$ {}_1Q_2 = m(u_2 - u_1) + {}_1W_2 $$

Equation of state: PV = mRT

State 1: $V_1 = mRT_1/P_1 = 4 \times 35.1 \times 1209.7 /(70 \times 144) = 16.849\ ft^3$

State 2: $V_2 = mRT_2/P_2 = 4 \times 35.1 \times 534.7 /(45 \times 144) = 11.585\ ft^3$

$$ {}_1W_2 = \tfrac{1}{2}(70 + 45)\ psi\ (\ 11.585 - 16.849)\ ft^3 \times \frac{144\ in^2/ft^2}{778\ lbf\text{-}ft/Btu} $$

$$ = -56.02\ Btu $$

Table F.4 at 77 F is $C_V = 0.156$ Btu/lbm-R

$$ {}_1Q_2 = mC_V(T_2 - T_1) + {}_1W_2 = 4 \times 0.156\ (75 - 750) - 56.02 = -477.2\ Btu $$

$$ {}_1W_2^{rev} = T_o(S_2 - S_1) - (U_2 - U_1) + {}_1Q_2\ (1 - T_o/T_H) $$

$$ = T_o m(s_2 - s_1) + {}_1W_2^{ac} - {}_1Q_2\ T_o/T_o $$

$$ = T_o m[C_P \ln(T_2 / T_1) - R \ln(P_2 / P_1)] + {}_1W_2^{ac} - {}_1Q_2 $$

$$ = 527.7 \times 4\ [\ 0.201 \ln \frac{534.7}{1209.7} - \frac{35.1}{778} \ln \frac{45}{70}\ ] - 56.02 + 477.2 $$

$$ = -304.3 - 56.02 + 477.2 = \mathbf{116.9\ Btu} $$

$$ {}_1I_2 = {}_1W_2^{rev} - {}_1W_2^{ac} = 116.9 - (-56.02) = \mathbf{172.9\ Btu} $$

8.156E

Fresh water can be produced from saltwater by evaporation and subsequent condensation. An example is shown in Fig. P8.45 where 300-lbm/s saltwater, state 1, comes from the condenser in a large power plant. The water is throttled to the saturated pressure in the flash evaporator and the vapor, state 2, is then condensed by cooling with sea water. As the evaporation takes place below atmospheric pressure, pumps must bring the liquid water flows back up to P_0. Assume that the saltwater has the same properties as pure water, the ambient is at 68 F, and that there are no external heat transfers. With the states as shown in the table below find the irreversibility in the throttling valve and in the condenser.

State	1	2	5	7	8
T [F]	86	77	74	63	68
h [Btu/lbm]	54.08	1095.1	42.09	31.08	36.09
s [Btu/lbm R]	0.1043	2.044	0.0821	0.0613	0.0708

C.V. Valve: $\dot{m}_1 = m_{ex} = \dot{m}_2 + \dot{m}_3$,

Energy Eq.: $h_1 = h_e$; Entropy Eq.: $s_i + s_{gen} = s_e$

$P_2 = P_{sat}(T_2 = T_3) = 0.4641$ psia

$h_e = h_1 \Rightarrow x_e = (54.08 - 45.08)/1050.0 = 0.008571$

$\Rightarrow s_e = 0.08769 + 0.008571 \times 1.9565 = 0.1045$ Btu/lbm R

$$\dot{m}_2 = (1 - x_e)\,\dot{m}_i = (1 - 0.008571)\,300 = 297.44 \text{ lbm/s}$$

$s_{gen} = s_e - s_i = 0.1045 - 0.1043 = 0.0002$ Btu/lbm R

$\dot{I} = \dot{m} T_0 s_{gen} = 300$ lbm/s $\times$ 528 R $\times$ 0.0002 Btu/lbm-R $= 31.68$ Btu/s

C.V. Condenser.

Energy Eq.: $\dot{m}_2 h_2 + \dot{m}_7 h_7 = \dot{m}_2 h_5 + \dot{m}_7 h_8 \Rightarrow$

$$\dot{m}_7 = \dot{m}_2 \times (h_2 - h_5)/(h_8 - h_7) = 297.44 \frac{1095.1 - 42.09}{36.09 - 31.08} = 62516 \frac{\text{lbm}}{\text{s}}$$

Entropy Eq.: $\dot{m}_2 s_2 + \dot{m}_7 s_7 + \dot{S}_{gen} = \dot{m}_2 s_5 + \dot{m}_7 s_8$

$$\dot{I} = T_0 \dot{S}_{gen} = T_0 \left[\dot{m}_2 (s_5 - s_2) + \dot{m}_7 (s_8 - s_7) \right]$$

$$= 528 \left[297.44(0.0821 - 2.044) + 62516(0.0708 - 0.0613) \right]$$

$= 528 \times 10.354 =$ **5467 Btu/s**

8.157E

A rock bed consists of 12 000 lbm granite and is at 160 F. A small house with lumped mass of 24 000 lbm wood and 2000 lbm iron is at 60 F. They are now brought to a uniform final temperature by circulating water between the rock bed and the house. Find the final temperature and the irreversibility in the process assuming an ambient at 60 F.

C.V. Total Rockbed and house. No work, no Q irreversible process.

Energy eq.: $m_{rock}(u_2 - u_1) + m_{wood}(u_2 - u_1) + m_{Fe}(u_2 - u_1) = 0$

Entropy Eq.: $m_{rock}(s_2 - s_1) + m_{wood}(s_2 - s_1) + m_{Fe}(s_2 - s_1) = S_{gen}$

$$(mC)_{rock} \ln \frac{T_2}{T_1} + (mC)_{wood} \ln \frac{T_2}{T_1} + (mC)_{Fe} \ln \frac{T_2}{T_1} = S_{gen}$$

Energy eq.: $(mC)_{rock}(T_2 - 160) + (mC_{wood} + mC_{Fe})(T_2 - 60) = 0$

$$12\,000 \times 0.212\,(T_2 - 160) + (24\,000 \times 0.33 + 2000 \times 0.11)(T_2 - 60) = 0$$

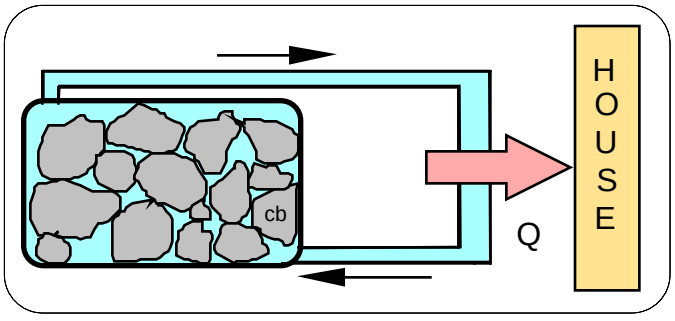
$$2544\,(T_2 - 160) + (7920 + 220)(T_2 - 60) = 0$$

$$T_2 = \mathbf{83.8\ F = 543.5\ R}$$

$$S_{gen} = \sum m_i(s_2 - s_1)_i = (mC)_{rock} \ln \frac{T_2}{T_1} + (mC)_{wood} \ln \frac{T_2}{T_1} + (mC)_{Fe} \ln \frac{T_2}{T_1}$$

$$= 2544 \ln \frac{543.5}{619.67} + (7920 + 220) \ln \frac{543.5}{519.67} = 35.26 \text{ Btu/R}$$

$${}_1I_2 = T_0\, S_{gen} = 519.67 \times 35.26 = \mathbf{18\ 324\ Btu}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.158E

Air enters the turbocharger compressor of an automotive engine at 14.7 lbf/in^2, 90 F, and exits at 25 lbf/in^2, as shown in Fig. P8.51. The air is cooled by 90 F in an intercooler before entering the engine. The isentropic efficiency of the compressor is 75%. Determine the temperature of the air entering the engine and the irreversibility of the compression-cooling process.

Solution:

a) Compressor. First ideal which is reversible adiabatic, constant s:

$$T_{2s} = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 550\ \text{R}\left(\frac{25}{14.7}\right)^{0.286} = 640.2\ \text{R}$$

$$-w_s = C_{P0}(T_{2s} - T_1) = 0.24(640.2 - 550) = 21.65\ \text{Btu/lbm}$$

Now the actual compressor

$$-w = -w_s/\eta_s = 21.65/0.75 = 28.87 = C_{P0}(T_2 - T_1) = 0.24(T_2 - 550)$$

$$\Rightarrow \quad T_2 = 670.3\ \text{R}$$

Cool down 90 F $\quad \Rightarrow \quad T_3 = 670.3 - 90 =$ **580.3 R**

b) Irreversibility from Eq.8.15 with rev. work from Eq.8.14, (q = 0 at T_H)

$$s_3 - s_1 = 0.24 \ln\frac{580.3}{550} - \frac{53.34}{778}\ln\frac{25}{14.7} = -0.0235\ \text{Btu/lbm R}$$

$$i = T(s_3 - s_1) - (h_3 - h_1) - w = T(s_3 - s_1) - C_P(T_3 - T_1) - C_P(T_1 - T_2)$$

$$= 550(-0.0235) - 0.24(-90) = \mathbf{+8.7\ Btu/lbm}$$

Exergy

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.159E

A heat pump has a coefficient of performance of 2 using a power input of 15000 Btu/h. Its low temperature is T_o, and the high temperature is 180 F, with ambient at T_o. Find the fluxes of exergy associated with the energy fluxes in and out.

First let us do the energies in and out

$$\text{COP} = \beta = \frac{\dot{Q}_H}{\dot{W}} \quad \Rightarrow \quad \dot{Q}_H = \beta\, \dot{W} = 2 \times 15\,000 \text{ Btu/h} = 30\,000 \text{ Btu/h}$$

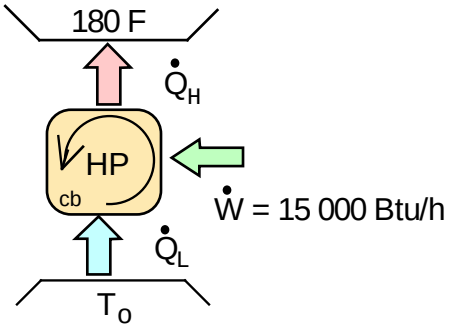
Energy Eq.: $\dot{Q}_L = \dot{Q}_H - \dot{W} = 30\,000 - 15\,000 = 15\,000$ Btu/h

Exergy flux in: $\dot{\Phi}_L = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L = \mathbf{0} \qquad (T_L = T_o)$

Exergy flux in: $\dot{\Phi}_W = \dot{W} = \mathbf{15\,000 \text{ Btu/h}}$

Exergy flux out: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H = \left(1 - \frac{536.7}{639.7}\right) 30\,000 = \mathbf{4830 \text{ Btu/h}}$

Remark: It destroys 15 000 – 4830 = 10 170 Btu/h of exergy.

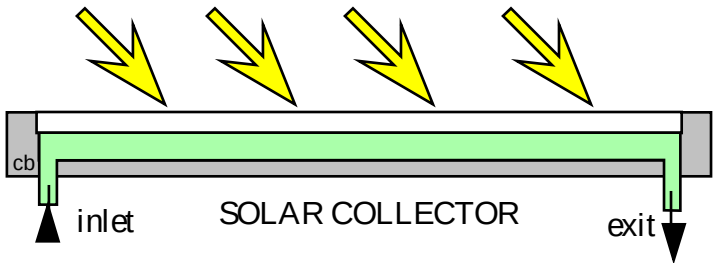


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.160E

A steady flow device receives R-410A at 125 psia, 100 F, and it exits at 15 psia, 100 F. Assume a reversible isothermal process. Find the change in specific exergy.

Solution:



Inlet Table F.9.2 : h_i = 135.96 Btu/lbm, s_i = 0.2763 Btu/lbm R

Exit Table F.9.2 : h_e = 141.10 Btu/lbm, s_e = 0.3411 Btu/lbm R

From Eq.8.23 or flow terms in Eq.8.38

$$\Delta\psi_{ie} = \psi_e - \psi_i = (h_e - h_i) - T_0(s_e - s_i)$$
$$= (141.10 - 135.96) - 536.7\ (0.3411 - 0.2763)$$
$$= \mathbf{-29.6\ Btu/lbm}$$

Remark: it is negative due to the pressure loss.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.161E

Consider the springtime melting of ice in the mountains, which gives cold water running in a river at 34 F while the air temperature is 68 F. What is the exergy of the water relative to the temperature of the ambient?

$\psi = h_1 - h_0 - T_0(s_1 - s_0)$ flow exergy from Eq.8.22

Approximate both states as saturated liquid

$\psi = 1.9973 - 36.088 - 527.67 \times (0.00405 - 0.07081) =$ **1.136 Btu/lbm**

Why is it positive? As the water is brought to 68 F it can be heated with q_L from a heat engine using q_H from atmosphere $T_H = T_0$ thus giving out work.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.162E

Compressed air for machines and tools in a plant is generated by a central compressor receiving air at 15 psia, 540 R, 1 lbm/s delivering it at 90 psia to a buffer tank and a distribution pipe. After flowing through the tank and pipe the air is at the ambient 540 R at its point of use. Assume a reversible adiabatic compressor and find the compressor exit temperature and the increase in air exergy through the compressor.

C.V. Compressor

Energy: $0 = h_1 - h_2 + w_C$; Entropy: $0 = s_1 - s_2 + 0$

$$s_2 - s_1 = s^0_{T2} - s^0_{T1} - R \ln(P_2/P_1) \quad \text{find } s^0_{T2} \text{ and then } T_2$$

or with constant specific heat

$$T_2 = T_1 \left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 540 \text{ R} \left(\frac{90}{15}\right)^{0.2857} = \mathbf{901\ R}$$

Exergy increase through the compressor matches with the compressor work

$$\psi_2 - \psi_1 = (h_2 - h_1) - T_0(s_2 - s_1) = h_2 - h_1 = C_P (T_2 - T_1) = w_C$$

$$= 0.24 \text{ Btu/lbm-R } (901 - 540) \text{ R} = \mathbf{86.6\ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.163E

For the air system in the previous problem find the increase in the air exergy from the inlet to the point of use. How much exergy was lost in the flow after the compressor exit?

From inlet, state 1 to final point of use state 3.

$$\psi_3 - \psi_1 = (h_3 - h_1) - T_0(s_3 - s_1) = 0 - T_0[0 - R \ln(P_3/P_1)]$$

$$= T_0 R \ln(P_3/P_1) = 537 \text{ R} \times (53.34/778) \text{ Btu/lbm-R} \times \ln (90/15)$$

$$= \mathbf{65.97 \text{ Btu/lbm}}$$

Compressor exit, reversible adiabatic, constant s process: $s_2 = s_1$

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 540 \text{ R} \left(\frac{90}{15}\right)^{0.2857} = 901 \text{ R}$$

So then

$$\psi_{lost} = \psi_2 - \psi_3 = -(\psi_3 - \psi_1) + (\psi_2 - \psi_1) = -(\psi_3 - \psi_1) + h_2 - h_1$$

$$= -(\psi_3 - \psi_1) + C_{P0}(T_2 - T_1)$$

$$= -65.97 \text{ kJ/kg} + 0.24 \text{ Btu/lbm-R } (901 - 540) \text{ R}$$

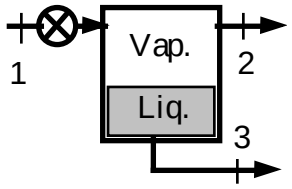
$$= \mathbf{20.67 \text{ btu/lbm}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.164E

A geothermal source provides 20 lbm/s of hot water at 80 lbf/in.^{2}, 280 F flowing into a flash evaporator that separates vapor and liquid at 30 lbf/in.^{2}. Find the three fluxes of exergy (inlet and two outlets) and the irreversibility rate.

C.V. Flash evaporator chamber. Steady flow with no work or heat transfer.



Cont. Eq.: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$;

Energy Eq.: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3$

Entropy Eq.: $\dot{m}_1 s_1 + \dot{S}_{gen} = \dot{m}_2 s_2 + \dot{m}_3 s_3$

Properties from Table F.7.1

$h_o = 45.08$, $h_1 = 249.17$, $h_2 = 1164.3$, $h_3 = 218.9$ Btu/lbm

$s_o = 0.08769$, $s_1 = 0.4098$, $s_2 = 1.6997$, $s_3 = 0.36815$ Btu/lbm R

$$h_1 = x h_2 + (1 - x) h_3 \quad => \quad x = \dot{m}_2/\dot{m}_1 = \frac{h_1 - h_3}{h_2 - h_3} = 0.03202$$

$$\dot{m}_2 = x\dot{m}_1 = 0.64 \text{ lbm/s} \qquad \dot{m}_3 = (1\text{-}x)\dot{m}_1 = 19.36 \text{ lbm/s}$$

$$\dot{S}_{gen} = 0.64 \times 1.6997 + 19.36 \times 0.36815 - 20 \times 0.4098 = 0.0192 \text{ Btu/s-R}$$

Flow exergy Eq.8.22: $\psi = (h - T_o s) - (h_o - T_o s_o) = h - h_o - T_o(s - s_o)$

$\psi_1 = 249.17 - 45.08 - 537 \times (0.4098 - 0.08769) = 31.117$ Btu/lbm

$\psi_2 = 1164.3 - 45.08 - 537 \times (1.6997 - 0.08769) = 253.57$ Btu/lbm

$\psi_3 = 218.9 - -45.08 - 537 \times (0.36815 - 0.08769) = 23.21$ Btu/lbm

$\dot{m}_1 \psi_1 =$ **622.3 Btu/s** $\dot{m}_2\psi_2 =$ **162.3 Btu/s** $\dot{m}_3\psi_3 =$ **449.3 Btu/s**

Balance of flow terms in Eq.8.38

$\dot{I} = \dot{m}_1 \psi_1 - \dot{m}_2 \psi_2 - \dot{m}_3\psi_3 =$ **10.7 Btu/s** $(= T_o \dot{S}_{gen})$

8.166E

An electric stove has one heating element at 600 F getting 750 W of electric power. It transfers 90% of the power to 2 lbm water in a kettle initially at 70 F, 1 atm, the rest 10% leaks to the room air. The water at a uniform T is brought to the boiling point. At the start of the process what is the rate of exergy transfer by: a) electrical input b) from heating element and c) into the water at T_{water}.

We take here the reference T to be the room 70 F = 529.67 R

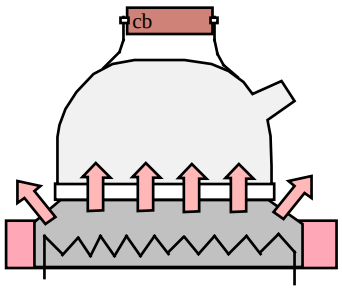
a) Work is exergy $\dot{\Phi} = \dot{W} =$ **750 W**

b) Heat transfer at 600 F is only partly exergy

$$\dot{\Phi} = \left(1 - \frac{T_o}{T_H}\right)\dot{Q} = \left(1 - \frac{529.67}{459.67 + 600}\right) 750 = \textbf{375 W}$$

c) Water receives heat transfer at 70 F as 90% of 750 W = 675 W

$$\dot{\Phi} = \left(1 - \frac{T_o}{T_{water}}\right)\dot{Q} = \left(1 - \frac{529.67}{459.67 + 70}\right) 675 = \textbf{0 W}$$



750 W at 600 F

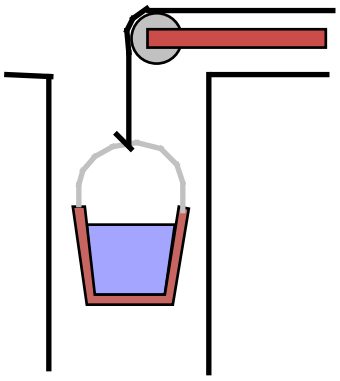
8.167E

A wood bucket (4 lbm) with 20 lbm hot liquid water, both at 180 F, is lowered 1300 ft down into a mineshaft. What is the exergy of the bucket and water with respect to the surface ambient at 70 F?



C.V. Bucket and water. Both thermal exergy and potential energy terms.

$v_1 \approx v_0$ for both wood and water so work to atm. is zero.

Use constant heat capacity table F.2 for wood and table F.7.1 (sat. liquid) for water.
From Eq.8.28

$$\phi_1 - \phi_0 = m_{wood}[u_1 - u_0 - T_0(s_1 - s_0)] + m_{H_2O}[u_1 - u_0 - T_0(s_1 - s_0)] + m_{tot}g(z_1 - z_0)$$

$$= 4[0.3(180 - 70) - 0.3 \times 530 \ln \frac{640}{530}] + 20[147.76 - 38.09$$

$$- 530(0.263 - 0.074)] + 24 \times 32.174 \times (-1300 / 25\,037)$$

$$= 12.05 + 199.3 - 40.1 = \mathbf{171.25\ Btu}$$

Recall 1 Btu/lbm = 25 037 ft^2/s^2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.168E

A 20-lbm iron disk brake on a car is at 50 F. Suddenly the brake pad hangs up, increasing the brake temperature by friction to 230 F while the car maintains constant speed. Find the change in exergy of the disk and the energy depletion of the car's gas tank due to this process alone. Assume that the engine has a thermal efficiency of 35%.

All the friction work is turned into internal energy of the disk brake.

$$m(u_2 - u_1) = {}_1Q_2 - {}_1W_2 \Rightarrow {}_1Q_2 = m_{Fe}C_{Fe}(T_2 - T_1)$$

$${}_1Q_2 = 20 \times 0.107 \times (230 - 50) = 385.2 \text{ Btu}$$

Change in s for a solid, Eq.8.11

$$m(s_2 - s_1) = mC \ln(T_2 / T_1) = 20 \times 0.107 \times \ln\left(\frac{690}{510}\right) = 0.6469 \text{ Btu/R}$$

No change in kinetic or potential energy, no volume change and neglect the work to the surroundings at P_0, so change in exergy is from Eq.8.27

$$\Delta\phi = m(u_2 - u_1) - T_0 m(s_2 - s_1) = 385.2 - 510 \times 0.6469 = \mathbf{55.28\ Btu}$$

$$W_{engine} = \eta_{th} Q_{gas} = {}_1Q_2 = \text{Friction work}$$

$$Q_{gas} = {}_1Q_2/\eta_{th} = 385.2/0.35 = \mathbf{1100\ Btu}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

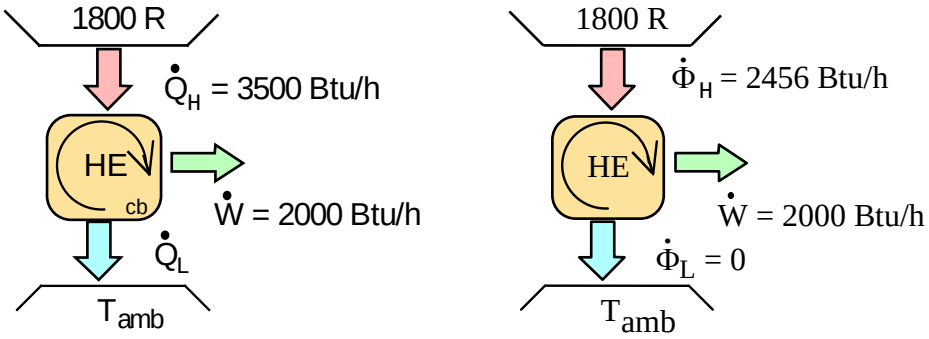
8.169E

Apply the exergy equation to find the exergy destruction in Problem 8.150E

Exergy flux in: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H = \left(1 - \frac{536.7}{1800}\right) 3500 \text{ Btu/h} = 2456 \text{ Btu/h}$

Exergy flux out: $\dot{\Phi}_L = \left(1 - \frac{T_o}{T_L}\right) \dot{Q}_L = \mathbf{0} \qquad (T_L = T_o)$

The other exergy flux out is the power $\dot{\Phi}_{out} = \dot{W} = 2000 \text{ Btu/h}$



The exergy balance equation Eq.8.38 for the HE becomes (steady state)

$$0 = \dot{\Phi}_H - \dot{\Phi}_L - \dot{W} - \dot{\Phi}_{destruction}$$

$$\dot{\Phi}_{destruction} = \dot{\Phi}_H - \dot{\Phi}_L - \dot{W} = 2456 \text{ Btu/h} - 0 - 2000 \text{ Btu/h}$$
$$= \mathbf{456 \text{ Btu/h}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.170E

The condenser in a power plant cools 20 lbm/s water at 120 F, quality 90% so it comes out as saturated liquid at 120 F. The cooling is done by ocean-water coming in at 60 F and returned to the ocean at 68 F. Find the transfer out of the water and the transfer into the ocean-water of both energy and exergy (4 terms).

Solution:
C.V. Water line. No work but heat transfer out.

Energy Eq.: $\dot{Q}_{out} = \dot{m}\,(h_1 - h_2) = 20(1010.99 - 87.99) =$ **18 460 Btu/s**

C.V. Ocean water line. No work but heat transfer in equals water heattransfer out

Energy Eq.: $q = h_4 - h_3 = 36.09 - 28.08 = 8.0$ Btu/lbm

$$\dot{m}_{ocean} = \dot{Q}_{out}/q = 18\,460 / 8.0 = 2308 \text{ kg/s}$$

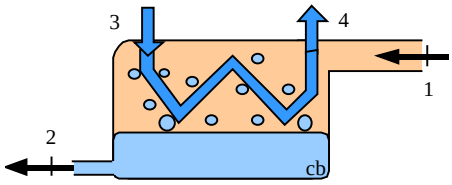
Exergy out of the water follows from flow term Eq.8.38 (we will use $T_o = 60$ F)

$$\dot{\Phi}_{out} = \dot{m}(\psi_1 - \dot{m}\psi_2) = \dot{m}\,[\,h_1 - h_2 - T_o\,(s_1 - s_2)\,]$$
$$= 20\,[\,1010.99 - 87.99 - 519.7(1.7567 - 0.1646)]$$
$$= \mathbf{1912\ Btu/s}$$

Exergy into the ocean water

$$\dot{\Phi}_{ocean} = \dot{m}_{ocean}(\psi_4 - \psi_3) = \dot{m}_{ocean}\,[\,h_4 - h_3 - T_o(s_4 - s_3)]$$
$$= 2308\,[\,8.0 - 519.7(0.0708 - 0.0555)]$$
$$= \mathbf{112\ Btu/s}$$

Notice there is a large amount of energy exchanged, but very little exergy.



Often the cooling media flows inside a long pipe carrying the energy away.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Device 2nd Law Efficiency

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.171E

A heat engine receives 3500 Btu/h heat transfer at 1800 R and gives out 1400 Btu/h as work with the rest as heat transfer to the ambient. Find its first and second law efficiencies.

First law efficiency is based on the energies

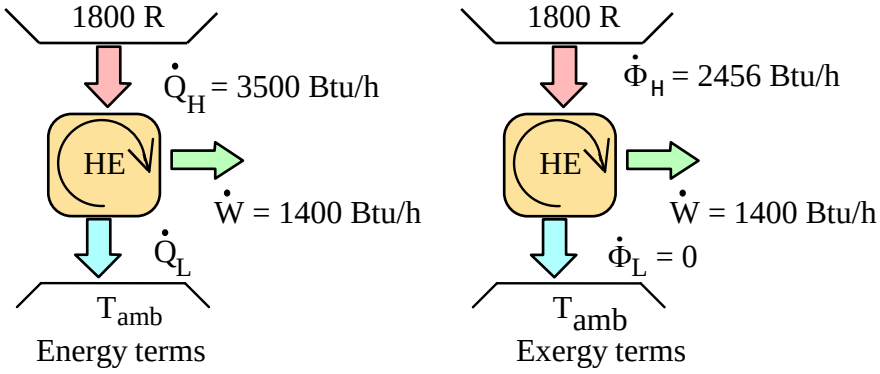
$$\eta_I = \dot{W}/\dot{Q}_H = \frac{1400}{3500} = \mathbf{0.4}$$

The second law efficiency is based on work out versus exergy in

Exergy flux in: $\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right)\dot{Q}_H = \left(1 - \frac{536.7}{1800}\right)3500 \text{ Btu/h} =$ **2456 btu/h**

$$\eta_{II} = \frac{\dot{W}}{\dot{\Phi}_H} = \frac{1400}{2456} = \mathbf{0.57}$$

Notice the exergy flux in is equal to the Carnot heat engine power output given 3500 Btu/h at 1800 R and rejecting energy to the ambient.

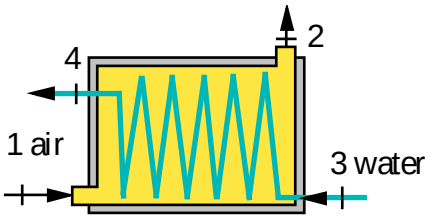


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.172E

A heat exchanger increases the exergy of 6 lbm/s water by 800 btu/lbm using 20 lbm/s air coming in at 2500 R and leaving with 250 Btu/lbm less exergy. What are the irreversibility and the second law efficiency?

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for air and water each. The two flows exchange energy with no heat transfer to/from the outside.



The irreversibility is the destruction of exergy (exergy) so

$$\dot{I} = \dot{\Phi}_{destruction} = \dot{\Phi}_{in} - \dot{\Phi}_{out} = 20 \times 250 - 6 \times 800 = \mathbf{200\ Btu/s}$$

The second law efficiency, Eq.8.32

$$\eta_{II} = \dot{\Phi}_{out} / \dot{\Phi}_{in} = \frac{6 \times 800}{20 \times 250} = \mathbf{0.96}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.173E

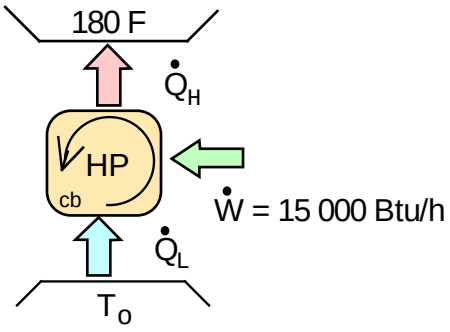
Find the second law efficiency of the heat pump in problem 8.159E.

The second law efficiency is a ratio of exergies namely what we want out divided by what we have to put in. Exergy from first term on RHS Eq. 8.38

$$\dot{\Phi}_H = \left(1 - \frac{T_o}{T_H}\right) \dot{Q}_H;$$

$$\dot{Q}_H = \beta\, \dot{W} = 2 \times 15\,000 \text{ Btu/h} = 30\,000 \text{ Btu/h}$$

$$\eta_{II} = \frac{\dot{\Phi}_H}{\dot{W}} = \left(1 - \frac{T_o}{T_H}\right) \frac{\dot{Q}_H}{\dot{W}} = \left(1 - \frac{536.7}{639.7}\right) \frac{30\,000}{15\,000} = \mathbf{0.32}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.174E

Find the isentropic efficiency and the second law efficiency for the compressor in Problem 8.145

C.V. Compressor. Assume adiabatic and neglect kinetic energies.

Energy Eq.4.13: $w = h_1 - h_2$

Entropy Eq.7.8: $s_2 = s_1 + s_{gen}$

We have two different cases, the ideal and the actual compressor.

State 1: F.9.2 $h_1 = 113.73$ Btu/lbm, $s_1 = 0.2772$ Btu/lbm-R

$h_2 = h_1 - w = 113.73 + 23.48 = 137.21$ kJ/kg

State 2: F.9.2 P, $h_2 = 137.21$ Btu/lbm, $T_2 = 100$ F, $s_2 = 0.2840$ Btu/lbm-R

State 2s: B.4.2 (P, $s = s_1$) $h_{2,s} = 133.44$ Btu/lbm

Actual compressor: $-w_{C,AC} = h_{2,AC} - h_1 = 137.21 - 113.73 = 23.48$ Btu/lbm

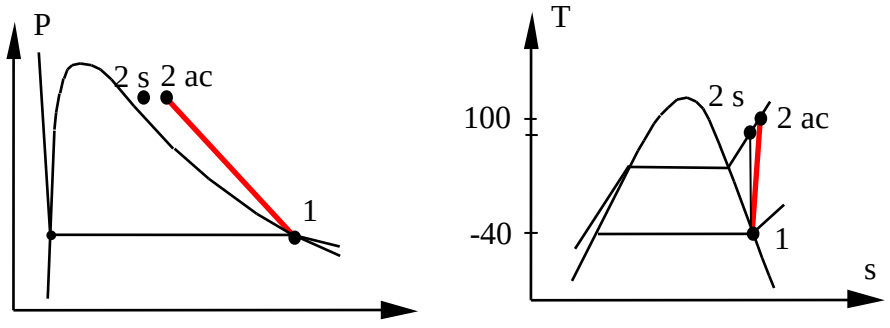
Ideal work: $-w_{c,s} = h_{2,s} - h_1 = 133.44 - 113.73 = 19.71$ Btu/lbm

Definition Eq.7.27: $\eta_c = w_{c,s}/w_{c,AC} = \mathbf{0.839}$

Rev. work Eq.8.29

$$w^{rev} = \psi_1 - \psi_2 = h_1 - h_2 - T_0 (s_1 - s_2)$$
$$= 113.73 - 137.21 - 536.7 (0.2772 - 0.2840)$$
$$= -23.48 + 3.65 = -19.83 \text{ Btu/lbm}$$

2^{nd} law efficiency: $\eta_{II} = \dfrac{w_{rev}}{w_{ac}} = \dfrac{-19.83}{-23.48} = \mathbf{0.8445}$ $\left(= \dfrac{w_{ac} + i}{w_{ac}} \right)$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.175E

A steam turbine has an inlet at 600 psia, and 900 F and actual exit of 1 atm with x = 1.0. Find its first law (isentropic) and the second-law efficiencies

C.V. Steam turbine

Energy Eq.4.13: $w = h_i - h_e$

Entropy Eq.7.9: $s_e = s_i + s_{gen}$

Inlet state: Table F.7.2 $h_i = 1462.92$ Btu/lbm; $s_i = 1.6766$ Btu/lbm R

Exit (actual) state: F.7.2 $h_e = 1150.49$ Btu/lbm; $s_e = 1.7567$ Btu/lbm R

Actual turbine energy equation

$$w = h_i - h_e = 312.43 \text{ Btu/lbm}$$

Ideal turbine reversible process so $s_{gen} = 0$ giving

$$s_{es} = s_i = 1.6766 = 0.3121 + x_{es} \times 1.4446$$

$$x_{es} = 0.94455, \; h_{es} = 180.13 + 0.94455 \times 970.35 = 1096.67$$

The energy equation for the ideal gives

$$w_s = h_i - h_{es} = 366.25 \text{ Btu/lbm}$$

The first law efficiency is the ratio of the two work terms

$$\eta_s = w/w_s = 312.43/366.25 = \mathbf{0.853}$$

The reversible work for the actual turbine states is, Eq.8.29

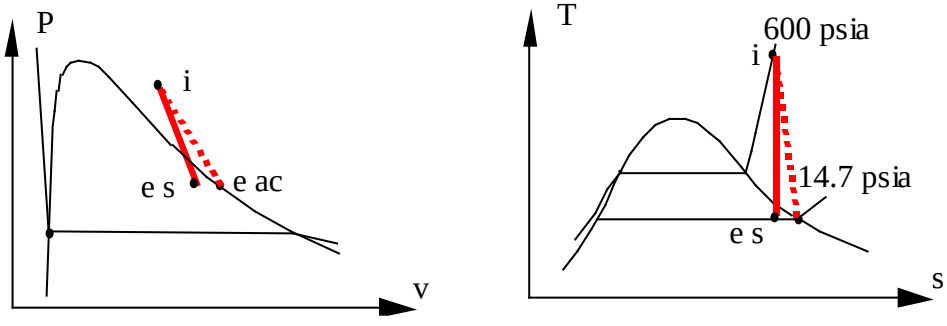
$$w^{rev} = (h_i - h_e) + T_o(s_e - s_i)$$

$$= 312.43 + 536.7(1.7567 - 1.6766)$$

$$= 312.43 + 42.99 = 355.4 \text{ Btu/lbm}$$

Second law efficiency Eq.8.31

$$\eta_{2^{nd}\,Law} = w/w_{rev} = 312.43/355.4 = \mathbf{0.879}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.176E

A heat engine operating with an evironment at 540 R produces 17 000 Btu/h of power output with a first law efficiency of 50%. It has a second law efficiency of 80% and T_L = 560 R. Find all the energy and exergy transfers in and out.

Solution:
From the definition of the first law efficiency

$$\dot{Q}_H = \dot{W} / \eta = \frac{17\ 000}{0.5} = \mathbf{34\ 000\ Btu/h}$$

Energy Eq.: $\dot{Q}_L = \dot{Q}_H - \dot{W} = 34\ 000 - 17\ 000 = \mathbf{17\ 000\ Btu/h}$

$$\dot{\Phi}_W = \dot{W} = \mathbf{17\ 000\ Btu/h}$$

From the definition of the second law efficiency $\eta_{II} = \dot{W}/\dot{\Phi}_H$, this requires that we assume the exergy rejected at 560 R is lost and not counted, otherwise the efficiency should be $\eta_{II} = \dot{W}/(\dot{\Phi}_H - \dot{\Phi}_L)$.

Exergy from source: $\dot{\Phi}_H = (1 - \frac{T_o}{T_H})\ \dot{Q}_H = \frac{17\ 000}{0.8} = \mathbf{21\ 250\ Btu/h}$

Exergy rejected: $\dot{\Phi}_L = (1 - \frac{T_o}{T_L})\ \dot{Q}_L = (1 - \frac{540}{560})\ 17\ 000 = \mathbf{607\ Btu/h}$

Notice from the $\dot{\Phi}_H$ form we could find the single characteristic T_H as

$$(1 - \frac{T_o}{T_H}) = 21\ 250\ \text{Btu/h} / \dot{Q}_H = 0.625 \quad \Rightarrow \quad T_H = 1440\ \text{R}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.177E

Air flows into a heat engine at ambient conditions 14.7 lbf/in.^{2}, 540 R, as shown in Fig. P8.111. Energy is supplied as 540 Btu per lbm air from a 2700 R source and in some part of the process a heat transfer loss of 135 Btu per lbm air happens at 1350 R. The air leaves the engine at 14.7 lbf/in.^{2}, 1440 R. Find the first- and the second-law efficiencies.

C.V. Engine out to reservoirs

$$h_i + q_H = q_L + h_e + w$$

Table F.5: $h_i = 129.18$ Btu/lbm, $s^o_{Ti} = 1.63979$ Btu/lbm R

$h_e = 353.483$ Btu/lbm, $s^o_{Te} = 1.88243$ Btu/lbm R

$$w_{ac} = 129.18 + 540 - 135 - 353.483 = 180.7 \text{ Btu/lbm}$$

$$\eta_{TH} = w/q_H = 180.7/540 = \mathbf{0.335}$$

For second law efficiency also a q to/from ambient

$$s_i + (q_H/T_H) + (q_0/T_0) = (q_{loss}/T_m) + s_e$$

$$q_0 = T_0\left[s_e - s_i + (q_{loss}/T_m) - (q_H/T_H)\right]$$

$$= 540\left(1.88243 - 1.63979 + \frac{135}{1350} - \frac{540}{2700}\right) = 77.02 \text{ Btu/lbm}$$

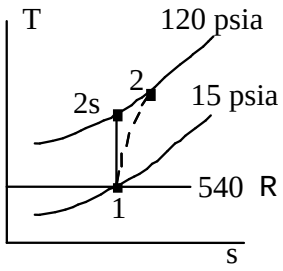
$$w_{rev} = h_i - h_e + q_H - q_{loss} + q_0 = w_{ac} + q_0 = 257.7 \text{ Btu/lbm}$$

$$\eta_{II} = w_{ac}/w_{rev} = 180.7/257.7 = \mathbf{0.70}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.178E

Air enters a compressor at ambient conditions, 15 psia, 540 R, and exits at 120 psia. If the isentropic compressor efficiency is 85%, what is the second-law efficiency of the compressor process?



Ideal (isentropic, Eq.6.23)

$T_{2s} = 540\ (8)^{0.2857} = 978.1$ R

$-w_s = 0.24\ (978.1 - 540) = 105.14$ Btu/lbm

$$-w = \frac{-w_s}{\eta_s} = \frac{105.14}{0.85} = 123.7 \text{ Btu/lbm}$$

Actual exit temperature

$$T_2 = T_1 + \frac{-w}{C_{P0}} = 540 + \frac{123.7}{0.24} = 1055 \text{ R}$$

Eq.6.16: $s_2 - s_1 = 0.24 \ln(1055/540) - (53.34/778) \ln 8 = 0.01817$ Btu/lbm-R

Exergy, Eq.8.23

$\psi_2 - \psi_1 = (h_2 - h_1) - T_0(s_2 - s_1) = 123.7 - 537\ (0.01817) = 113.94$ Btu/lbm

2nd law efficiency, Eq.8.32 or 8.34 (but for a compressor):

$$\eta_{II} = \frac{\psi_2 - \psi_1}{-w} = \frac{113.94}{123.7} = \mathbf{0.92}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.179E

Consider that the air in the previous problem after the compressor flows in a pipe to an air tool and at that point the temperature has dropped to ambient 540 R and an air pressure of 110 psia. What is the second law efficiency for the total system?

C.V. Compressor

Energy: $0 = h_1 - h_2 + w_C$; Entropy: $0 = s_1 - s_2 + 0$

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 540\left(\frac{120}{15}\right)^{0.2857} = 978.1 \text{ R}$$

Exergy increase through the compressor matches with the ideal compressor work

$w_{C\,s} = h_2 - h_1 = C_P(T_2 - T_1) = 0.24(978.1 - 540)$ Btu/lbm = 105.14 Btu/lbm

The actual compressor work is

$$w_{C\,ac} = w_{C\,s} / \eta_{C\,s} = 105.14/0.85 = 123.7 \text{ Btu/lbm}$$

From inlet, state 1 to final point of use state 3.

$$\psi_3 - \psi_1 = (h_3 - h_1) - T_0(s_3 - s_1) = 0 - T_0[0 - R \ln(P_3/P_1)]$$

$$= T_0 R \ln(P_3/P_1) = 537 \text{ R} \times (53.34/778) \text{ Btu/lbmR} \times \ln (110/15)$$

$$= 73.36 \text{ Btu/lbm}$$

So then the second law efficiency is the gain $(\psi_3 - \psi_1)$ over the source $w_{C\,ac}$ as

$$\eta_{II} = \frac{\psi_3 - \psi_1}{w_{C\,ac}} = \frac{73.36}{123.7} = \mathbf{0.59}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.180E

A compressor is used to bring saturated water vapor at 103 lbf/in.^{2} up to 2000 lbf/in.^{2}, where the actual exit temperature is 1200 F. Find the irreversibility and the second law efficiency.

Inlet state: Table F.7.1 $h_i = 1188.4$ Btu/lbm, $s_i = 1.601$ Btu/lbm R

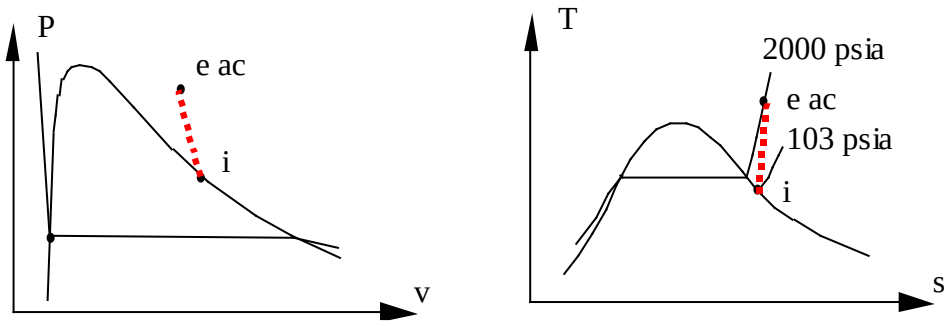
Actual compressor F.7.2: $h_e = 1598.6$ Btu/lbm, $s_e = 1.6398$ Btu/lbm R

Energy Eq. actual compressor: $-w_{c,ac} = h_e - h_i = 410.2$ Btu/lbm

Eq.8.13: $i = T_0(s_e - s_i) = 536.67 \times (1.6398 - 1.601) =$ **20.82 Btu/lbm**

Eq.8.15: $w_{rev} = i + w_{c,ac} = 20.82 + (-410.2) = -389.4$ Btu/lbm

$\eta_{II} = -w_{rev}/(-w_{c,ac}) = 389.4 / 410.2 =$ **0.949**



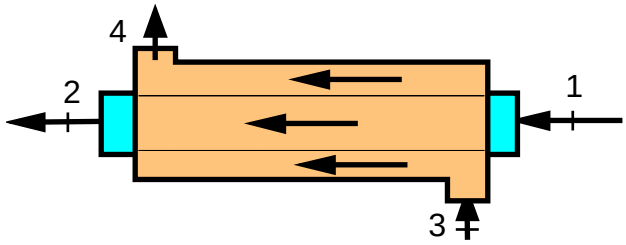
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.181E

A coflowing (same direction) heat exchanger has one line with 0.5 lbm/s oxygen at 68 F and 30 psia entering and the other line has 1.2 lbm/s nitrogen at 20 psia and 900 R entering. The heat exchanger is long enough so that the two flows exit at the same temperature. Use constant heat capacities and find the exit temperature and the second law efficiency for the heat exchanger assuming ambient at 68 F.

Solution:

C.V. Heat exchanger, steady 2 flows in and two flows out.



Energy Eq.4.10: $\dot{m}_{O2}h_1 + \dot{m}_{N2}h_3 = \dot{m}_{O2}h_2 + \dot{m}_{N2}h_4$

Same exit tempearture so $T_4 = T_2$ with values from Table F.4

$$\dot{m}_{O2}C_{P\,O2}T_1 + \dot{m}_{N2}C_{P\,N2}T_3 = (\dot{m}_{O2}C_{P\,O2} + \dot{m}_{N2}C_{P\,N2})T_2$$

$$T_2 = \frac{0.5 \times 0.22 \times 527.7 + 1.2 \times 0.249 \times 900}{0.5 \times 0.22 + 1.2 \times 0.249} = \frac{326.97}{0.4088} = \mathbf{800\ R}$$

The second law efficiency for a heat exchanger is the ratio of the exergy gain by one fluid divided by the exergy drop in the other fluid. For each flow exergy is Eq.8.23 include mass flow rate as in Eq.8.38

For the oxygen flow:

$$\dot{m}_{O2}(\psi_2 - \psi_1) = \dot{m}_{O2}\,[\,h_2 - h_1 - T_0\,(s_2 - s_1)\,]$$

$$= \dot{m}_{O2}\,[\,C_P(T_2 - T_1) - T_0\,[\,C_P \ln(T_2 / T_1) - R \ln(P_2 / P_1)\,]$$

$$= \dot{m}_{O2}C_P\,[\,T_2 - T_1 - T_0 \ln(T_2 / T_1)\,]$$

$$= 0.5 \times 0.22\,[\,800 - 527.7 - 536.7 \ln(800/527.7)\,] = 5.389\ \text{Btu/s}$$

For the nitrogen flow

$$\dot{m}_{N2}(\psi_3 - \psi_4) = \dot{m}_{N2}C_P\,[\,T_3 - T_4 - T_0 \ln(T_3 / T_4)\,]$$

$$= 1.2 \times 0.249\,[\,900 - 800 - 536.7 \ln(900/800)\,] = 10.992\ \text{Btu/s}$$

From Eq.8.32

$$\eta_{2^{nd}\,Law} = \frac{\dot{m}_{O2}(\psi_1 - \psi_2)}{\dot{m}_{N2}(\psi_3 - \psi_4)} = \frac{5.389}{10.992} = \mathbf{0.49}$$

8.182E

Calculate the irreversibility for the process described in Problem 4.211E, assuming that the heat transfer is with the surroundings at 61 F.

C.V. Cylinder volume out to T_o = 61 F.

Continuity Eq.4.15: $m_2 - m_1 = m_{in}$

Energy Eq.4.16: $m_2u_2 - m_1u_1 = m_{in}h_{line} + {}_1Q_2 - {}_1W_2$

Entropy Eq.7.12: $m_2 s_2 - m_1s_1 = m_is_i + {}_1Q_2 / T_o + {}_1S_{2\,gen}$

Process: P_1 is constant to stops, then constant V to state 2 at P_2

State 1: P_1, T_1 $\quad m_1 = \dfrac{P_1V}{RT_1} = \dfrac{45 \times 9 \times 144}{53.34 \times 519.7} = 2.104$ lbm

State 2:

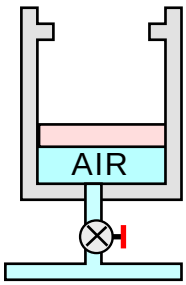
Open to 60 lbf/in^2, T_2 = 630 R

Table F.5:

h_i = 266.13 btu/lbm

u_1 = 88.68 Btu/lbm

u_2 = 107.62 Btu/lbm



Only work as piston moves (V changes) while P = P_1 until V = V_{stop}

$${}_1W_2 = \int PdV = P_1(V_{stop} - V_1) = 45 \times (36 - 9)\frac{144}{778} = 224.9 \text{ Btu}$$

$$m_2 = P_2V_2/RT_2 = \frac{60 \times 36 \times 144}{53.34 \times 630} = 9.256 \text{ lbm}, \quad m_i = 7.152 \text{ lbm}$$

$${}_1Q_2 = m_2u_2 - m_1u_1 - m_i h_i + {}_1W_2$$

$$= 9.256 \times 107.62 - 2.104 \times 88.68 - 7.152 \times 266.13 + 224.9$$

$$= -868.9 \text{ Btu}$$

Use from table F.4: C_p = 0.24, R = 53.34 / 778 = 0.06856 Btu/lbm R,

$$I = T_o\,{}_1S_{2\,gen} = T_o\,[\,m_1\,(s_2 - s_1) + m_i\,(s_2 - s_i)] - {}_1Q_2$$

$$= 520.7[2.104(C_p \ln \frac{630}{519.7} - R \ln \frac{60}{45}) + 7.152(C_p \ln \frac{630}{1100} - R \ln \frac{60}{75})]$$

$$- (- 868.9)$$

$$= 520.7\,(0.05569 - 0.8473) + 868.9$$

$$= \mathbf{456.7\ Btu}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.183E

Calculate the exergy of the system (aluminum plus gas) at the initial and final states of Problem 6.245E, and also the irreversibility.

State 1: $T_1 = 400$ F $v_1 = 2/2.862 = 0.6988$ $P_1 = 300$ psi

Ideal gas $v_2 = v_1(300 / 220)(537 / 860) = 0.595$; $v_o = 8.904 = RT_o / P_o$

The metal does not change volume so the terms as Eq.8.22 are added

$$\phi_1 = m_{gas}\phi_{gas} + m_{Al}\phi_{Al\,1}$$

$$= m_{gas}C_v (T_1 - T_o) - m_{gas}T_o \left[C_p \ln \frac{T_1}{T_o} - R \ln \frac{P_1}{P_o}\right] + m_{gas}P_o (v_1 - v_o)$$

$$+ m_{Al} [C (T_1 - T_o) - T_o C \ln (T_1 / T_o)]_{Al}$$

$$\phi_1 = 2.862[0.156(400-77) - 537(0.201 \ln \frac{860}{537} - \frac{35.1}{778} \ln \frac{300}{14.7})$$

$$+ 14.7 (0.6988 - 8.904)(\frac{144}{778})] + 8 \times 0.21 [400 -77 - 537 \ln \frac{860}{537}]$$

$$= 143.96 + 117.78 = \mathbf{261.74\ Btu}$$

$$\phi_2 = 2.862[0.156(77 - 77) - 537 (0.201 \ln \frac{537}{537} - \frac{35.1}{778} \ln \frac{220}{14.7})$$

$$+ 14.7(0.595 - 8.904)(\frac{144}{778})] + 8 \times 0.21 [77 -77 - 537 \ln \frac{537}{537}]$$

$$= 122.91 + 0 = \mathbf{122.91\ Btu}$$

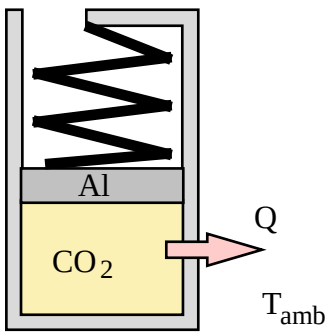
$${}_1W_{2\,CO_2} = \int PdV = 0.5(P_1 + P_2)(V_2 - V_1) = [(300 +220)/2] (1.703 - 2) \frac{144}{778}$$

$$= -14.29 \text{ Btu}$$

$${}_1I_2 = \phi_1 - \phi_2 + (1 - T_o/T_H)\, {}_1Q_2 - {}_1W_2^{AC} + P_o m(V_2 - V_1)$$

$$= 261.74 - 122.91 + 0 - (-14.29) + 14.7 \times 2.862 \times \frac{144}{778} (0.595 - 0.6988)$$

$$= \mathbf{152.3\ Btu}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.184E

Air in a piston/cylinder arrangement, shown in Fig. P8.135, is at 30 lbf/in.^{2}, 540 R with a volume of 20 ft^3. If the piston is at the stops the volume is 40 ft^3 and a pressure of 60 lbf/in.^{2} is required. The air is then heated from the initial state to 2700 R by a 3400 R reservoir. Find the total irreversibility in the process assuming surroundings are at 70 F.

Solution:

Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Entropy Eq,: $m(s_2 - s_1) = \int dQ/T + {}_1S_{2\,gen}$

Process: $P = P_0 + \alpha(V-V_0)$ if $V \le V_{stop}$

Information: $P_{stop} = P_0 + \alpha(V_{stop}-V_0)$

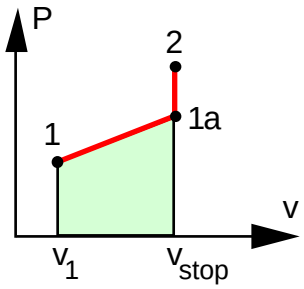
Eq. of state $\Rightarrow$ $T_{stop} = T_1 P_{stop} V_{stop}/P_1 V_1 = 2160 < T_2$

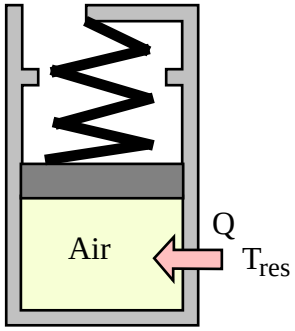
So the piston will hit the stops => $V_2 = V_{stop}$

$$P_2 = (T_2/T_{stop})\, P_{stop} = (2700/2160)\, 60 = 75 \text{ psia} = 2.5\, P_1$$

State 1:

$$m_2 = m_1 = \frac{P_1 V_1}{RT_1} = \frac{30 \times 20 \times 144}{53.34 \times 540} = 3.0 \text{ lbm}$$





$${}_1W_2 = \tfrac{1}{2}(P_1 + P_{stop})(V_{stop} - V_1) = \tfrac{1}{2}(30 + 60)(40 - 20) = 166.6 \text{ Btu}$$

$${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = 3(518.165 - 92.16) + 166.6 = 1444.6 \text{ Btu}$$

$$s_2 - s_1 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1)$$

$$= 2.0561 - 1.6398 - (53.34/778) \ln (2.5) = 0.3535 \text{ Btu/lbm R}$$

Take control volume as total out to reservoir at T_{RES}

$${}_1S_{2\,gen\,tot} = m(s_2 - s_2) - {}_1Q_2/T_{RES} = \mathbf{0.6356\ Btu/R}$$

$${}_1I_2 = T_0({}_1S_{2\,gen}) = 530 \times 0.6356 = \mathbf{337\ Btu}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.185E

A piston/cylinder arrangement has a load on the piston so it maintains constant pressure. It contains 1 lbm of steam at 80 lbf/in.^{2}, 50% quality. Heat from a reservoir at 1300 F brings the steam to 1000 F. Find the second-law efficiency for this process. Note that no formula is given for this particular case, so determine a reasonable expression for it.

1: $P_1, x_1 \Rightarrow v_1 = 2.7458$ ft^3/lbm, $h_1 = 732.905$ Btu/lbm,

$s_1 = 1.0374$ Btu/lbm R

2: $P_2 = P_1, T_2 \Rightarrow v_2 = 10.831$ ft^3/lbm, $h_2 = 1532.6$ Btu/lbm,

$s_2 = 1.9453$ Btu/lbm R

$$m(u_2 - u_1) = {}_1Q_2 - {}_1W_2 = {}_1Q_2 - P(V_2 - V_1)$$

${}_1Q_2 = m(u_2 - u_1) + Pm(v_2 - v_1) = m(h_2 - h_1) = 799.7$ Btu

${}_1W_2 = Pm(v_2 - v_1) = 119.72$ Btu

${}_1W_{2\ \text{to atm}} = P_0 m(v_2 - v_1) = 22$ Btu

Useful work out = ${}_1W_2 - {}_1W_{2\ \text{to atm}} = 119.72 - 22 = 97.72$ Btu

$$\Delta\phi_{\text{reservoir}} = \left(1 - \frac{T_0}{T_{\text{res}}}\right) {}_1Q_2 = \left(1 - \frac{536.67}{1759.67}\right) 799.7 = 556 \text{ Btu}$$

$$\eta_{II} = W_{\text{net}}/\Delta\phi = \frac{97.72}{556} = \mathbf{0.176}$$

Remark: You could argue that the stored exergy (exergy) should be accounted for in the second law efficiency, but it is not available from this device alone.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

8.186E

The exit nozzle in a jet engine receives air at 2100 R, 20 psia with negligible kinetic energy. The exit pressure is 10 psia and the actual exit temperature is 1780 R. What is the actual exit velocity and the second law efficiency?

Solution:

C.V. Nozzle with air has no work, no heat transfer.

Energy eq.: $h_i = h_e + \frac{1}{2}\mathbf{V}_{ex}^2$

Entropy Eq.: $s_i + s_{gen} = s_e$

$$\frac{1}{2}\mathbf{V}_{ex}^2 = h_i - h_e = 532.57 - 444.36 = 88.21 \text{ Btu/lbm}$$

$$\mathbf{V}_{ex} = \sqrt{2 \times 88.21 \times 25\,037} = \mathbf{2102 \text{ ft s}^{-1}}$$

Recall 1 Btu/lbm = 25 037 ft^2/s^2. This was the actual nozzle. Now we can do the reversible nozzle, which then must have a q.

Energy eq.: $h_i + q = h_e + \frac{1}{2}\mathbf{V}_{ex\ rev}^2$

Entropy Eq.: $s_i + q/T_o = s_e \quad \Rightarrow \quad q = T_o (s_e - s_i)$

$$q = T_o\left[C \ln \frac{T_e}{T_i} - R \ln \frac{P_e}{P_i} \right] = 536.7 \left[0.24 \ln \frac{1780}{2100} - \frac{53.34}{778.17} \ln \frac{10}{20} \right]$$

$$= 4.198 \text{ Btu/lbm}$$

$$\frac{1}{2}\mathbf{V}_{ex\ rev}^2 = h_i + q - h_e = 88.21 + 4.198 = 92.408 \text{ Btu/lbm}$$

$$\eta_{II} = \frac{1}{2}\mathbf{V}_{ex}^2 / \frac{1}{2}\mathbf{V}_{ex\ rev}^2 = 88.21 / 92.408 = \mathbf{0.95}$$

Notice the reversible nozzle is not isentropic (there is a heat transfer).

In-Text Concept Questions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.a

Consider a Rankine cycle without superheat. How many single properties are needed to determine the cycle? Repeat the answer for a cycle with superheat.

a. No superheat. Two single properties.
High pressure (or temperature) and **low pressure** (or **temperature**). This assumes the condenser output is saturated liquid and the boiler output is saturated vapor. Physically the high pressure is determined by the pump and the low temperature is determined by the cooling medium and the heat echanger.

b. Superheat. Three single properties.
High pressure and **temperature** and **low pressure** (or **temperature**). This assumes the condenser output is saturated liquid. Physically the high pressure is determined by the pump and the high temperature by the heat transfer from the hot source. The low temperature is determined by the cooling medium and the heat echanger.

9.b

Which component determines the high pressure in a Rankine cycle? What determines the low pressure?

The high pressure in the Rankine cycle is determined by the pump. The low pressure is determined as the saturation pressure for the temperature you can cool to in the condenser.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.c

What is the difference between an open and a closed feedwater heater?

The open feedwater heater mixes the two flows at the extraction pressure and thus requires two feedwater pumps.

The closed feedwater heater does not mix the flows but let them exchange energy (it is a two fluid heat exchanger). The flows do not have to be at the same pressure. The condensing source flow is dumped into the next lower pressure feedwater heater or the condenser or it is pumped up to line pressure by a drip pump and added to the feedwater line.

9.d

In a cogenerating power plant, what is cogenerated?

The electricity is cogenerated. The main product is a steam supply. Such an arrangement is also known as Combined Heat and Power CHP.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.e

A refrigerator in my 20^{o}C kitchen uses R-134a and I want to make ice cubes at –5^{o}C. What is the minimum high P and the maximum low P it can use?

Since the R-134a must give heat transfer out to the kitchen air at 20^{o}C, it must at least be that hot at state 3.

From Table B.5.1: $P_3 = P_2 = P_{sat}$ = **573 kPa** is minimum high P.

Since the R-134a must absorb heat transfer at the freezers –5^{o}C, it must at least be that cold at state 4.

From Table B.5.1: $P_1 = P_4 = P_{sat}$ = **245 kPa** is maximum low P.

9.f

How many parameters are needed to completely determine a standard vapor compression refrigeration cycle?

Two parameters: The high pressure and the low pressure. This assumes the exit of the condenser is saturated liquid and the exit of the evaporator is saturated vapor.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Concept-Study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.1

Is a steam power plant running in a Carnot cycle? Name the four processes.

No. It runs in a Rankine cycle.

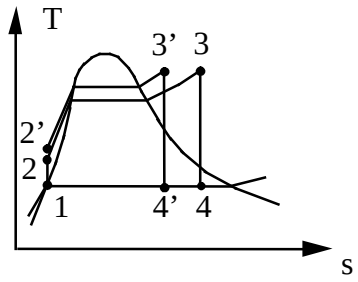
1-2:	An isentropic compression (constant s)	Pump
2-3:	An isobaric heating (constant P)	Boiler
3-4:	An isentropic expansion (constant s)	Turbine
4-1:	An isobaric cooling, heat rejection (constant P)	Condenser

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.2

Raising the boiler pressure in a Rankine cycle for fixed superheat and condenser temperatures in what direction do these change: turbine work, pump work and turbine exit T or x.

Turbine work: about the same P up, but v down
Turbine exit T: same if it was two-phase, down if sup. vapor
Turbine exit x: down
Pump work: up

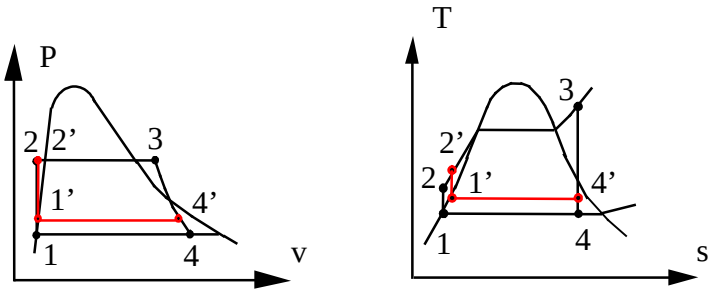


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.3

For other properties fixed in a Rankine cycle raising the condenser temperature causes changes in which work and heat transfer terms?

This results in less turbine work out.
An increase in heat rejection.
A small reduction in pump work.
A small reduction in boiler heat addition.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.4

Mention two benefits of a reheat cycle.

The reheat raises the average temperature at which you add heat.

The reheat process brings the states at the lower pressure further out in the superheated vapor region and thus raises the quality (if two-phase) in the last turbine section.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.5

What is the benefit of the moisture separator in the powerplant of Problem 4.121?

You avoid larger droplets in the turbine and raise the quality for the later stages.

9.6

Instead of the moisture separator in Problem 4.121 what could have been done to remove any liquid in the flow?

A reheat could be done to re-boil the liquid and even superheat it.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.7

Can the energy removed in a power plant condenser be useful?

Yes.

In some applications it can be used for heating buildings locally or as district heating. Other uses could be to heat greenhouses or as general process steam in a food process or paper mill. These applications are all based on economics and scale. The condenser then has to operate at a higher temperature than it otherwise would.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.8

If the district heating, see Fig.1.1, should supply hot water at 90^{o}C what is the lowest possible condenser pressure with water as the working substance?

The condenser temperature must be higher than 90^{o}C for which the saturation pressure is 70.14 kPa.

P > **70.14 kPa**

Pipes in the power plant

Pipes in the ground for distribution

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.9

What is the mass flow rate through the condensate pump in Fig. 9.14?

We need to check the continuity equation around several CVs.

Do control volume around HP turbine:

Number in 1000 kg/h: 0 = + 320 – 28 – 28 – 12 – out to LP turbine
out to LP turbine = 252 000 kg/h

which matches with Fig.: 227 000 in condenser + 25 000 from trap

Condensate pump (main) has **252 000 kg/h**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.10

A heat pump for a 20^{o}C house uses R-410A and the outside is at –5^{o}C. What is the minimum high P and the maximum low P it can use?

As the heat pump must be able to heat at 20^{o}C that becomes the smallest possible condensing temperature and thus P > P_{sat} = **1444 kPa**.

It must absorb heat from –5^{o}C and thus must be colder in the evaporation process so P < P_{sat} = **679 kPa.**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.11

A heat pump uses carbon dioxide and it is required that it condenses at a minimum of 22^{o}C and receives energy from the outside on a winter day at -10^{o}C. What restrictions does that place on the operating pressures?

The high pressure $P > P_{sat}$ = 6003 kPa, close to critical P = 7377 kPa

The low pressure $P < P_{sat}$ = 2649 kPa

Notice for carbon dioxide that the low pressure is fairly high.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.12

Since any heat transfer is driven by a temperature difference, how does that affect all the real cycles relative to the ideal cycles?

Heat transfers are given as $\dot{Q} = CA\,\Delta T$ so to have a reasonable rate the area and the temperature difference must be large. The working substance then must have a different temperature than the ambient it exchanges energy with. This gives a smaller temperature difference for a heat engine with a lower efficiency as a result. The refrigerator or heat pump must have the working substance with a higher temperature difference than the reservoirs and thus a lower coefficient of performance (COP).

The smaller CA is, the larger ΔT must be for a certain magnitude of the heat transfer rate. This can be a design problem, think about the front end air intake grill for a modern car which is very small compared to a car 20 years ago.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Simple Rankine cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.13

A steam power plant as shown in Fig. 9.3 operating in a Rankine cycle has saturated vapor at 3.0 MPa leaving the boiler. The turbine exhausts to the condenser operating at 10 kPa. Find the specific work and heat transfer in each of the ideal components and the cycle efficiency.

Solution:

Cycle is determined by: (P_3, x_3, $P_1 = P_4$, assume $x_1 = 0$)

C.V. Pump Reversible and adiabatic.

Energy: $w_p = h_2 - h_1$; Entropy: $s_2 = s_1$

since incompressible it is easier to find work (positive in) as

$w_p = \int v\, dP = v_1 (P_2 - P_1) = 0.00101\ (3000 - 10) = 3.02$ kJ/kg

$\Rightarrow h_2 = h_1 + w_p = 191.81 + 3.02 = 194.83$ kJ/kg

C.V. Boiler : $q_H = h_3 - h_2 = 2804.14 - 194.83 =$ **2609.3 kJ/kg**

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$

$s_4 = s_3 = 6.1869 = 0.6492 + x_4\ (7.501)$ $\Rightarrow$ $x_4 = 0.7383$

$\Rightarrow h_4 = 191.81 + 0.7383\ (2392.82) = 1958.34$ kJ/kg

$w_T = 2804.14 - 1958.34 =$ **845.8 kJ/kg**

C.V. Condenser : $q_L = h_4 - h_1 = 1958.34 - 191.81 =$ **1766.5 kJ/kg**

$\eta_{cycle} = w_{net} / q_H = (w_T + w_p) / q_H = (845.8 - 3.0) / 2609.3 =$ **0.323**

9.14

Consider a solar-energy-powered ideal Rankine cycle that uses water as the working fluid. Saturated vapor leaves the solar collector at 1000 kPa, and the condenser pressure is 10 kPa. Determine the thermal efficiency of this cycle.

Solution:

C.V. H_2O ideal Rankine cycle

Cycle is determined by: (P_3, x_3, $P_1 = P_4$, assume $x_1 = 0$)

State 3: 1000 kPa, sat vap, $h_3 = 2778.08$ kJ/kg, $s_3 = 6.5864$ kJ/kg K

CV Turbine adiabatic and reversible so second law gives

$$s_4 = s_3 = 6.5864 = 0.6492 + x_4 \times 7.5010 \quad \Rightarrow \quad x_4 = 0.7915$$

$$h_4 = 191.81 + 0.7915 \times 2392.82 = 2085.73 \text{ kJ/kg}$$

The energy equation gives

$$w_T = h_3 - h_4 = 2778.08 - 2085.73 = 692.35 \text{ kJ/kg}$$

C.V. pump and incompressible liquid gives work into pump

$$w_P = v_1(P_2 - P_1) = 0.00101(1000 - 10) = 1.0 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 191.81 + 1.0 = 192.81 \text{ kJ/kg}$$

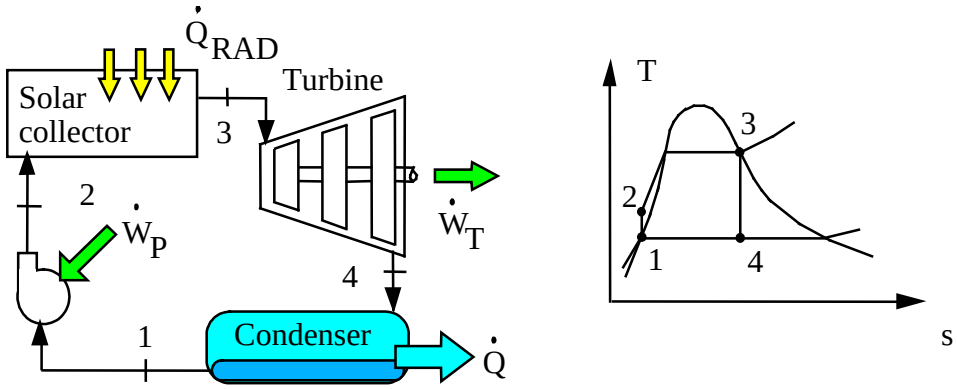
C.V. boiler gives the heat transfer from the energy equation as

$$q_H = h_3 - h_2 = 2778.08 - 192.81 = 2585.3 \text{ kJ/kg}$$

The cycle net work and efficiency are found as

$$w_{NET} = w_T - w_P = 692.35 - 1.0 = 691.35 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = 691.35/2585.3 = \mathbf{0.267}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.15

The power plant in the previous problem is augmented with a natural gas burner to superheat the water to 300°C before entering the turbine. Find the cycle efficiency with this configuration and the specific heat transfer added by the natural gas burner.

Solution:

C.V. H_2O ideal Rankine cycle

Cycle is determined by: (P_3, T_3, $P_1 = P_4$, assume $x_1 = 0$)

State 3: 1000 kPa, 300°C, $h_3 = 3051.15$ kJ/kg, $s_3 = 7.1228$ kJ/kg K

CV Turbine adiabatic and reversible so second law gives

$$s_4 = s_3 = 7.1228 = 0.6492 + x_4 \times 7.5010 \quad \Rightarrow \quad x_4 = 0.86303$$

$$h_4 = 191.81 + 0.86303 \times 2392.82 = 2256.88 \text{ kJ/kg}$$

The energy equation gives

$$w_T = h_3 - h_4 = 3051.15 - 2256.88 = 794.27 \text{ kJ/kg}$$

C.V. pump and incompressible liquid gives work into pump

$$w_P = v_1(P_2 - P_1) = 0.00101(1000 - 10) = 1.0 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 191.81 + 1.0 = 192.81 \text{ kJ/kg}$$

C.V. boiler gives the heat transfer from the energy equation as

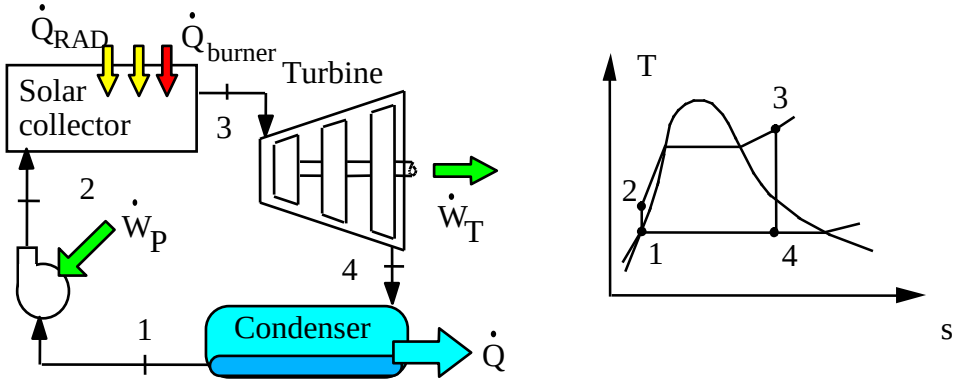
$$q_H = h_3 - h_2 = 3051.15 - 192.81 = 2858.3 \text{ kJ/kg}$$

$$q_{H\,gas} = h_3 - {}_{g\,1000\,kPa} = 3051.15 - 2778.08 = \mathbf{273.07\ kJ/kg}$$

The cycle net work and efficiency are found as

$$w_{NET} = w_T - w_P = 794.27 - 1.0 = 793.27 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = 793.27/2858.3 = \mathbf{0.277}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.16

A utility runs a Rankine cycle with a water boiler at 3.0 MPa and the cycle has the highest and lowest temperatures of 450°C and 60°C respectively. Find the plant efficiency and the efficiency of a Carnot cycle with the same temperatures.

Solution:

The states properties from Tables B.1.1 and B.1.3

1: 60°C, x = 0 => $h_1 = 251.11$, $v_1 = 0.001017$ m^3/kg, $P_{sat} = 19.94$ kPa

3: 3.0 MPa , 450°C => $h_3 = 3344$ kJ/kg, $s_3 = 7.0833$ kJ/kg K

C.V. Pump Reversible and adiabatic.

Energy: $w_p = h_2 - h_1$; Entropy: $s_2 = s_1$

since incompressible it is easier to find work (positive in) as

$$w_p = \int v\, dP = v_1 (P_2 - P_1) = 0.001017\ (3000 - 19.94) = 3.03 \text{ kJ/kg}$$

$$\Rightarrow h_2 = h_1 + w_p = 251.11 + 3.03 = 254.14 \text{ kJ/kg}$$

C.V. Boiler : $q_H = h_3 - h_2 = 3344 - 254.14 = 3089.86$ kJ/kg

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$

$$s_4 = s_3 = 7.0833 = 0.8311 + x_4\ (7.0784) \quad \Rightarrow \quad x_4 = 0.8833$$

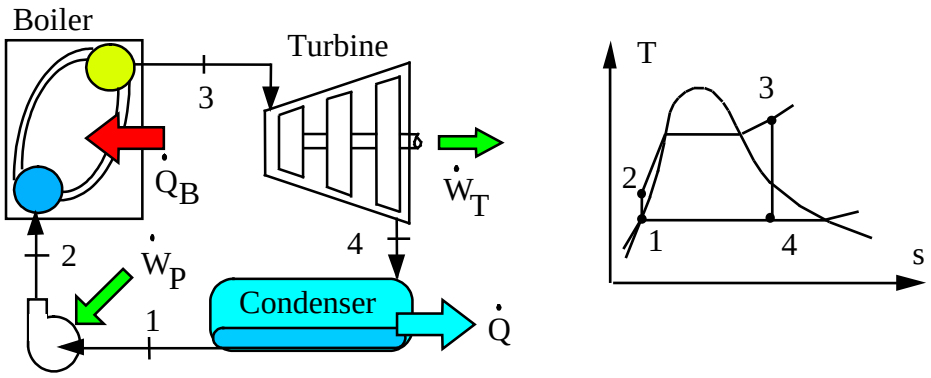
$$\Rightarrow h_4 = 251.11 + 0.8833\ (2358.48) = 2334.36 \text{ kJ/kg}$$

$$w_T = 3344 - 2334.36 = 1009.6 \text{ kJ/kg}$$

C.V. Condenser : $q_L = h_4 - h_1 = 2334.36 - 251.11 = 2083.25$ kJ/kg

$$\eta_{cycle} = w_{net} / q_H = (w_T + w_p) / q_H = (1009.6 - 3.03) / 3089.86 = \mathbf{0.326}$$

$$\eta_{carnot} = 1 - T_L / T_H = 1 - \frac{273.15 + 60}{273.15 + 450} = \mathbf{0.54}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.17

The power plant in the previous problem has a too low quality in the low pressure turbine section so the plant wants to increase the superheat. What should the superheat be so the quality of the water in the turbine stays above 92%.

Cycle is determined by: (P_3, T_1, x_4, assume $x_1 = 0$)

Consider the turbine and its exhaust at condenser 60°C, 92% quality.

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$, $x_4 = 0.92$

$$s_4 = s_3 = 0.8311 + x_4\,(7.0784) = 7.34323 \text{ kJ/kgK}$$

Look in B.1.3, 3 MPa match s:

$$T_3 = 500 + 100\,\frac{7.34323 - 7.2337}{7.5084 - 7.2337} = \mathbf{539.9°C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.18

A power plant for a polar expedition uses ammonia which is heated to 80°C at 1000 kPa in the boiler and the condenser is maintained at -15°C. Find the cycle efficiency.

Solution:

Standard Rankine cycle with superheat. From the listed information we get from Table B.2.2

State 1: $h_1 = 111.66$ kJ/kg, $v_1 = 0.001519$ m^3/kg,

$P_1 = 236.3$ kPa, $s = 0.4538$ kJ/kgK

State 3: $h_3 = 1614.6$ kJ/kg, $s_3 = 5.4971$ kJ/kgK

C.V. Tubine: Energy: $w_{T,s} = h_3 - h_4$;

Entropy: $s_4 = s_3 = 5.4971$ kJ/kg K

$$\Rightarrow \quad x_4 = \frac{s_4 - s_f}{s_{fg}} = \frac{5.4971 - 0.4538}{5.0859} = 0.9916 \ ;$$

$$h_4 = 111.66 + 0.9916 \times 1312.9 = 1413.56 \text{ kJ/kg}$$

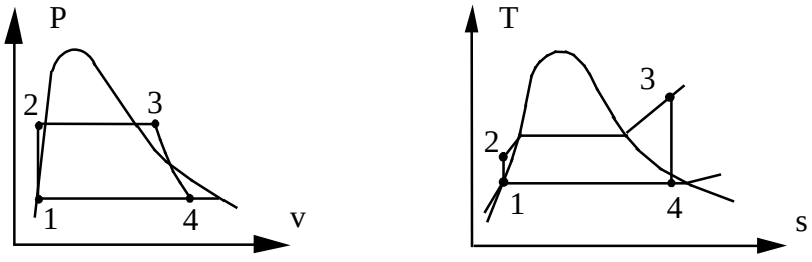
$$w_{T,s} = 1614.6 - 1413.56 = 201.04 \text{ kJ/kg}$$

C.V. Pump: $w_P = \int v \, dP = v_1(P_2 - P_1) = 0.001519(1000 - 236.3) = 1.16$ kJ/kg

$$\Rightarrow \quad h_2 = h_1 + w_P = 111.66 + 1.16 = 112.8 \text{ kJ/kg}$$

C.V. Boiler: $q_H = h_3 - h_2 = 1614.6 - 112.8 = 1501.8$ kJ/kg

$$\eta_{CYCLE} = w_{NET}/q_H = \frac{201.04 - 1.16}{1501.8} = \mathbf{0.133}$$



Comment: The cycle efficiency is low due to the low high temperature.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.19

A Rankine cycle with R-410A has the boiler at 3 MPa superheating to 180°C and the condenser operates at 800 kPa. Find all four energy transfers and the cycle efficiency.

Standard Rankine cycle given by ($P_2 = P_3$, T_3, P_1, assume $x_1 = 0$)

From Table B4:

State 1 (P, x) : $v_1 = 0.000855$ m^3/kg, $h_1 = 57.76$ kJ/kg (at 0°C)

State 3 (P, T): $h_3 = 445.09$ kJ/kg, $s_3 = 1.3661$ kJ/kg-K

State 4 (800 kPa, $s = s_3$): $h_4 = 385.97$ kJ/kg interpolated superheated vapor.

C.V. Pump: $w_P = \int v\, dP = v_1(P_2 - P_1) = 0.000855\ (3000 - 800) =$ **1.881 kJ/kg**

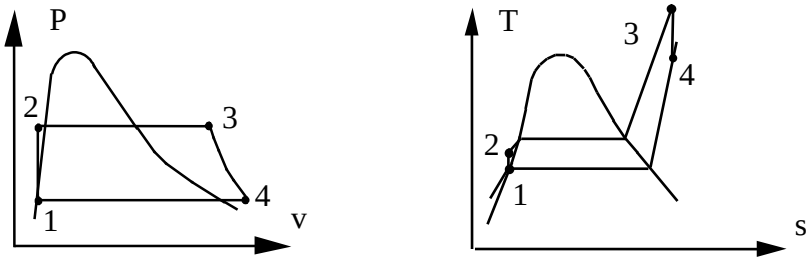
$$\Rightarrow h_2 = h_1 + w_P = 57.76 + 1.881 = 59.64 \text{ kJ/kg}$$

C.V. Boiler: $q_H = h_3 - h_2 = 445.09 - 59.64 =$ **385.45 kJ/kg**

C.V. Tubine: Energy: $w_{T,s} = h_3 - h_4 = 445.09 - 385.97 =$ **59.12 kJ/kg**

C.V. Condenser: $q_L = h_4 - h_1 = 385.97 - 57.76 =$ **328.21 kJ/kg**

$$\eta_{CYCLE} = w_{NET}/q_H = \frac{59.12 - 1.881}{385.45} = \mathbf{0.148}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.20

A steam power plant has a high pressure of 3 MPa and it maintains 60°C in the condenser. A condensing turbine is used, but the quality should not be lower than 90% at any state in the turbine. For a turbine power output of 8 MW find the work and heat transfer in all components and the cycle efficiency.

Solution:

Based on the standard Rankine cycle and Table B.1.

State 1: Sat. liquid. $P_1 = 19.94$ kPa, $h_1 = 251.11$ kJ/kg, $v_1 = 0.001017$ m^3/kg

Consider C.V. pump

Energy: $h_2 - h_1 = w_p = v_1 (P_2 - P_1) = 0.001017\ (3000 - 19.94) = 3.03$ kJ/kg

State 2: $P_2 = 3000$ kPa, $h_2 = h_1 + w_p = 251.11 + 3.03 = 254.1$ kJ/kg

State 4: $P_4 = P_1 = 19.94$ kPa, $x = 0.9$

$$s_4 = s_f + x_4\, s_{fg} = 0.8311 + 0.9 \times 7.0784 = 7.20166 \text{ kJ/kg-K}$$

$$h_4 = h_f + x_4\, h_{fg} = 251.11 + 0.9 \times 2358.48 = 2373.74 \text{ kJ/kg}$$

Consider the turbine for which $s_4 = s_3$.

State 3: Table B.2.2 3000 kPa, $s_3 = 7.20166$ kJ/kg K => $h_3 = 3432.5$ kJ/kg

Turbine: $w_T = h_3 - h_4 = 3432.5 - 2373.74 = 1058.8$ kJ/kg

Boiler: $q_H = h_3 - h_2 = 3432.5 - 254.1 = 3178.4$ kJ/kg

Condenser: $q_L = h_4 - h = 2373.74 - 251.1 = 2122.6$ kJ/kg

Efficiency: $\eta_{TH} = w_{NET}/q_H = (w_T - w_P)/q_H = \dfrac{1058.8 - 3.03}{3178.4} = \mathbf{0.332}$

Scaling: $\dot{m} = \dot{W}_T/w_T = 8\,000$ kW / 1058.8 kJ/kg = 7.555 kg/s

$$\dot{W}_p = \dot{m}\, w_p = \mathbf{22.9\ kW};\ \dot{Q}_H = \dot{m}\, q_H = \mathbf{24\ MW},\ \dot{Q}_L = \dot{m}\, q_L = \mathbf{16\ MW}$$

9.21

A supply of geothermal hot water is to be used as the energy source in an ideal Rankine cycle, with R-134a as the cycle working fluid. Saturated vapor R-134a leaves the boiler at a temperature of 85°C, and the condenser temperature is 40°C. Calculate the thermal efficiency of this cycle.

Solution:

CV: Pump (use R-134a Table B.5)

$$w_P = h_2 - h_1 = \int_1^2 v dP \approx v_1(P_2 - P_1)$$

$$= 0.000873(2926.2 - 1017.0) = 1.67 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 256.54 + 1.67 = 258.21 \text{ kJ/kg}$$

CV: Boiler

$$q_H = h_3 - h_2 = 428.10 - 258.21 = 169.89 \text{ kJ/kg}$$

CV: Turbine

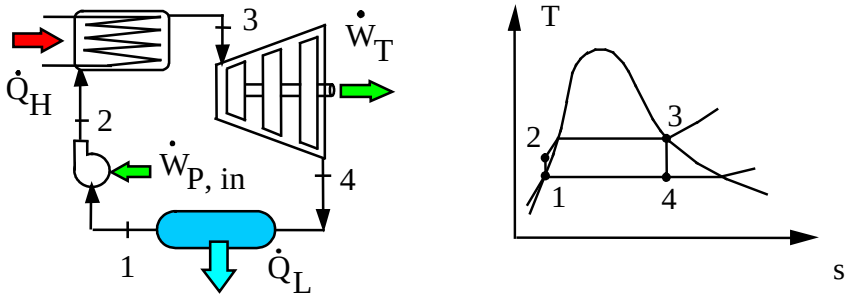
$$s_4 = s_3 = 1.6782 = 1.1909 + x_4 \times 0.5214 \Rightarrow \quad x_4 = 0.9346$$

$$h_4 = 256.54 + 0.9346 \times 163.28 = 409.14 \text{ kJ/kg}$$

Energy Eq.: $w_T = h_3 - h_4 = 428.1 - 409.14 = 18.96$ kJ/kg

$$w_{NET} = w_T - w_P = 18.96 - 1.67 = 17.29 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = 17.29/169.89 = \mathbf{0.102}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.22

Do Problem 9.21 with R-410A as the working fluid and boiler exit at 4000 kPa, 70°C.

A supply of geothermal hot water is to be used as the energy source in an ideal Rankine cycle, with R-134a as the cycle working fluid. Saturated vapor R-134a leaves the boiler at a temperature of 85°C, and the condenser temperature is 40°C. Calculate the thermal efficiency of this cycle.

Solution:

CV: Pump (use R-410A Table B.4)

$$w_P = h_2 - h_1 = \int_1^2 v dP \approx v_1(P_2 - P_1) = 0.001025(4000 - 2420.7) = 1.619 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 124.09 + 1.619 = 125.71 \text{ kJ/kg}$$

CV: Boiler: $q_H = h_3 - h_2 = 287.88 - 125.71 = 162.17$ kJ/kg

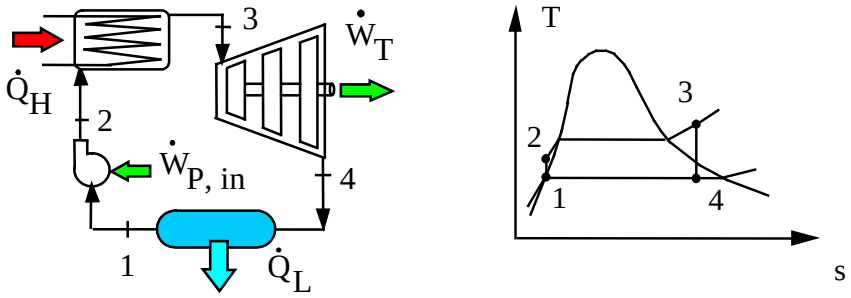
CV: Turbine

$$s_4 = s_3 = 0.93396 = 0.4473 + x_4 \times 0.5079, \Rightarrow \quad x_4 = 0.9582$$

$$h_4 = 124.09 + 0.9582 \times 159.04 = 276.48 \text{ kJ/kg}$$

$$w_T = h_3 - h_4 = 287.88 - 276.48 = 11.4 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = (11.4 - 1.62)/162.17 = \mathbf{0.060}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.23

A low temperature power plant operates with R-410A maintaining -20°C in the condenser, a high pressure of 3 MPa with superheat. Find the temperature out of the boiler/superheater so the turbine exit temperature is 60°C and find the overall cycle efficiency.

State 1: $P_1 = 399.6$ kPa, $v_1 = 0.000803$ m^3/kg, $h_1 = 28.24$ kJ/kg

State 4: $P_4 = P_1 \approx 400$ kPa, $h_4 = 343.58$ kJ/kg, $s_4 = 1.3242$ kJ/kg-K

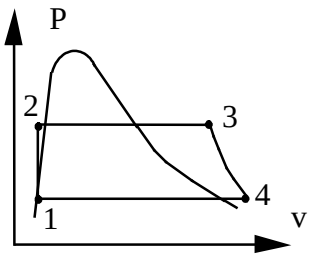
State 3: 3 MPa, $s = s_4$ ⇨ $h_3 = 426.56$ kJ/kg, $T_3 =$ **163.6°C**

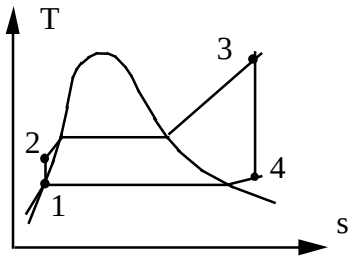
Pump: $w_p = v_1 (P_2 - P_1) = 0.000803$ m^3/kg (3000 – 399.6) kPa = 2.09 kJ/kg

Boiler: $q_H = h_3 - h_2 = 426.56 - (28.24 + 2.09) = 396.23$ kJ/kg

Turbine: $w_T = h_3 - h_4 = 426.56 - 343.58 = 82.98$ kJ/kg

Efficiency: $\eta_{TH} = w_{NET}/q_H = (w_T - w_P)/q_H = \dfrac{82.98 - 2.09}{396.23} =$ **0.204**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.24

A low temperature power plant should produce a turbine work of 2.5 MW. It operates with carbon dioxide maintaining -10°C in the condenser, a high pressure of 6 MPa and it superheats to 100°C. Find the turbine exit temperature, the mass flow rate required and the overall cycle efficiency.

State 1: $v_1 = 0.001017\ m^3/kg$, $h_1 = 63.62$ kJ/kg, $P_1 = 2648.7$ kPa

State 3: $h_3 = 421.69$ kJ/kg, $s_3 = 1.4241$ kJ/kg-K

State 4: (2648.7 kPa, $s = s_3$) Do a double linear interpolation in B.3.2.

At 2000 kPa: 14.775°C, h = 362.84; At 3000 kPa: 44.096°C, h = 382.98

Then at 2648.7 kPa: $T_4 = \mathbf{33.79^oC}$, $h_4 = 375.9$ kJ/kg

[use CATT3 (entry P, T) for accuracy then T = 34.5°C, h = 376.3 kJ/kg]

C.V. Pump: $w_P = \int v\, dP = v_1(P_2 - P_1) = 0.001017\ (6000 - 2648.7) = 3.408$ kJ/kg

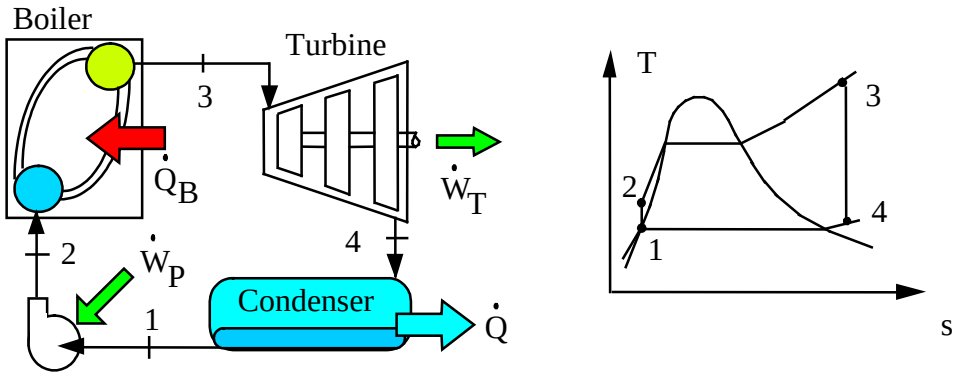
$$\Rightarrow h_2 = h_1 + w_P = 63.62 + 3.408 = 67.03 \text{ kJ/kg}$$

C.V. Boiler: $q_H = h_3 - h_2 = 421.69 - 67.03 = 354.66$ kJ/kg

C.V. Tubine: Energy: $w_{T,s} = h_3 - h_4 = 421.69 - 375.9 = \mathbf{45.79\ kJ/kg}$

Scaling: $\dot{m} = \dot{W}_T / w_T = 2\,500\ kW / 45.79\ kJ/kg = \mathbf{54.6\ kg/s}$

$$\eta_{CYCLE} = w_{NET}/q_H = \frac{45.79 - 3.408}{354.66} = \mathbf{0.129}$$

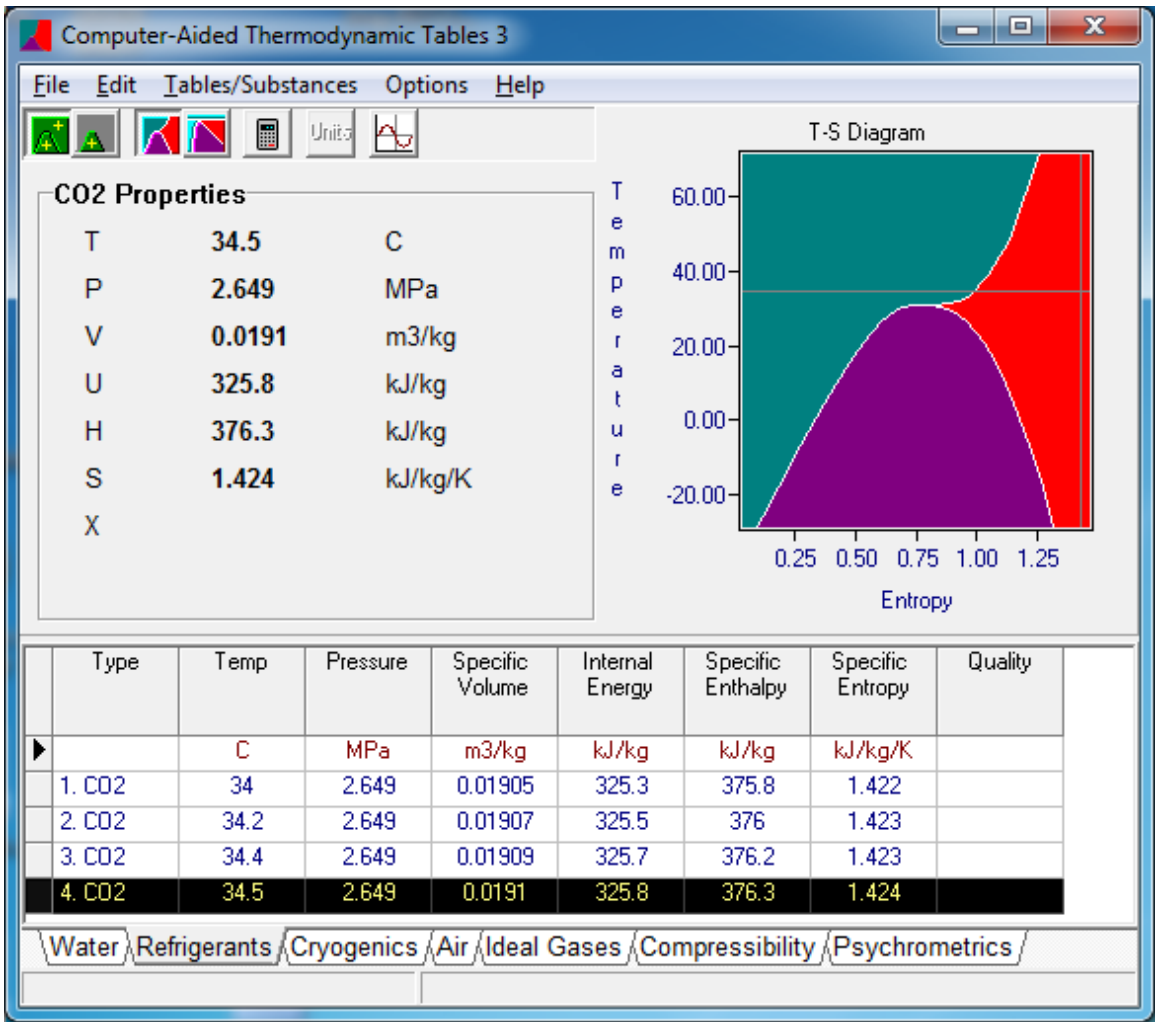


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Here are the CATT3 entries I used for locating state 4.:

Start out at P = 2.648.7 kPa = 2.6487 MPa, T = 34^{o}C the s is then too low

For some reason the entry (P,s) does not work (it iterates out of bounce, to be fixed in next edition of the CATT program)



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.25

Do Problem 9.21 with ammonia as the working fluid.

A supply of geothermal hot water is to be used as the energy source in an ideal Rankine cycle, with R-134a as the cycle working fluid. Saturated vapor R-134a leaves the boiler at a temperature of 85°C, and the condenser temperature is 40°C. Calculate the thermal efficiency of this cycle.

Solution:

CV: Pump (use Ammonia Table B.2)

$$w_P = h_2 - h_1 = \int_1^2 v dP = v_1(P_2 - P_1)$$

$$= 0.001725(4608.6 - 1554.9) = 5.27 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 371.43 + 5.27 = 376.7 \text{ kJ/kg}$$

CV: Boiler

$$q_H = h_3 - h_2 = 1447.8 - 376.7 = 1071.1 \text{ kJ/kg}$$

CV: Turbine

$$s_4 = s_3 = 4.3901 = 1.3574 + x_4 \times 3.5088 \quad \Rightarrow \quad x_4 = 0.8643$$

$$h_4 = 371.43 + 0.8643 \times 1098.8 = 1321.13 \text{ kJ/kg}$$

Energy Eq.:

$$w_T = h_3 - h_4 = 1447.8 - 1321.13 = 126.67 \text{ kJ/kg}$$

$$w_{NET} = w_T - w_P = 126.67 - 5.27 = 121.4 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = 121.4/1071.1 = \mathbf{0.113}$$

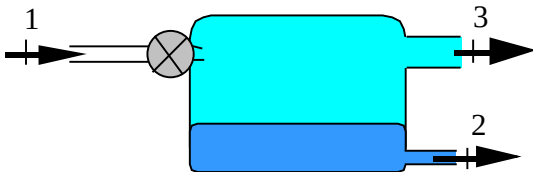
9.26

Geothermal water can be used directly as a source to a steam turbine. Consider 10 kg/s water at 500 kPa, 150^{o}C brought to a flash chamber where it is throttled to 200 kPa as shown in Fig. P9.26. From the chamber saturated vapor at 200 kPa flows to the turbine with an exit at 10 kPa. From state 4 it is cooled in a condenser and pumped back into the ground. Determine quality at the turbine exit and the power that can be obtained from the turbine.

Solution:



Two-phase out of the valve. The liquid drops to the bottom.

Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$

Energy Eq.4.10: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} + \int d\dot{Q}/T = \dot{m}_2 s_2 + \dot{m}_3 s_3$

Process: $\dot{Q} = 0$, irreversible (throttle)

B.1.1 $h_1 = 632.18$ kJ/kg, $s_1 = 1.8417$ kJ/kg K

B.1.2 $h_3 = 2706.63$ kJ/kg, $s_3 = 7.1271$ kJ/kg K, $h_2 = 504.68$ kJ/kg,

From the energy equation we solve for the flow rate out to turbine

$$\dot{m}_3 = \dot{m}_1(h_1 - h_2)/(h_3 - h_2) = 10 \times 0.0579 = 0.579 \text{ kg/s}$$

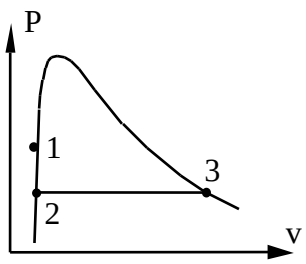
The flow through the turbine is rev. and adiabatic thus isentropic

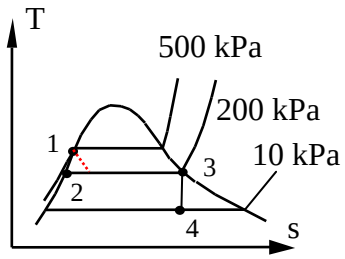
State 4: $s_4 = s_3 = 7.1271 = 0.6492 + x_4 \times 7.5010$ => $x_4 =$ **0.8636**

$h_4 = 191.81 + x_4 \times 2392.82 = 2258.25$ kJ/kg

$w_T = h_3 - h_4 = 2706.63 - 2258.25 = 448.38$ kJ/kg

$\dot{W}_T = \dot{m}_3 w_T = 0.579$ kg/s $\times$ 448.38 kJ/kg = **259.6 kW**



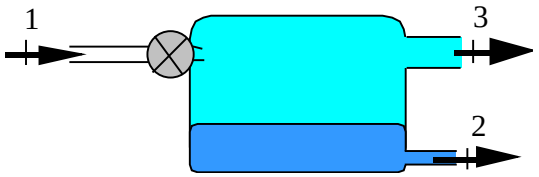


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.27

Some geothermal location have higher pressure and temperature so assume the geothermal power plant as in problem 9.26 but with a supply as saturated liquid at 250^{o}C. For this case the flash chamber operates at 1000 kPa. For a supply of 10 kg/s determine the mass flow that goes through the turbine and the power output.

Solution:



Two-phase out of the valve. The liquid drops to the bottom.

Continuity Eq.4.9: $\dot{m}_1 = \dot{m}_2 + \dot{m}_3$

Energy Eq.4.10: $\dot{m}_1 h_1 = \dot{m}_2 h_2 + \dot{m}_3 h_3$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{S}_{gen} + \int d\dot{Q}/T = \dot{m}_2 s_2 + \dot{m}_3 s_3$

Process: $\dot{Q} = 0$, irreversible (throttle)

B.1.1 $h_1 = 1085.34$ kJ/kg

B.1.2 $h_3 = 2778.08$ kJ/kg, $h_{fg} = 2015.29$ kJ/kg, $h_2 = 762.79$ kJ/kg,

From the energy equation we solve for the flow rate out to turbine

$$\dot{m}_3 = \dot{m}_1 \frac{h_1 - h_2}{h_3 - h_2} = 10 \frac{1085.34 - 762.79}{2015.29} = 10 \times 0.16 = \mathbf{1.6\ kg/s}$$

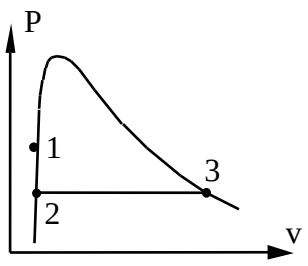
The flow through the turbine is rev. and adiabatic thus isentropic

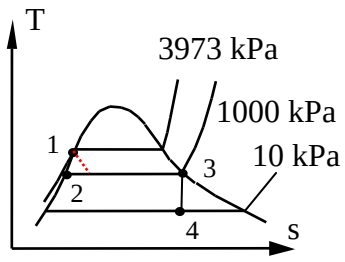
State 4: $s_4 = s_3 = 6.5864 = 0.6492 + x_4 \times 7.5010 \Rightarrow x_4 = 0.79152$

$h_4 = 191.81 + x_4 \times 2392.82 = 2085.775$ kJ/kg

$w_T = h_3 - h_4 = 2778.08 - 2085.775 = 692.3$ kJ/kg

$$\dot{W}_T = \dot{m}_3 w_T = 1.6 \text{ kg/s} \times 692.3 \text{ kJ/kg} = \mathbf{1107.7\ kW}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.28

With a higher supply pressure and temperature of the geothermal source it is possible to have two flash evaporators as shown in Fig. P9.28. Assume the supply is saturated water at 250^{o}C and the first chamber flashes to 2000 kPa and saturated liquid at state 2 is flashed to 500 kPa with the saturated vapor out added to the turbine which has an exit state of 10 kPa with quality 78%. For a supply of 10 kg/s determine the mass flow that goes through the turbine and the power output.

The enthalpies in kJ/kg for the states in the flow diagram are:

$h_1 = 1085.34,\ h_2 = 908.77,\ h_3 = 2799.51,\ h_{fg\ 2000\ kPa} = 1890.74,$

$h_6 = 640.21,\quad h_5 = 2748.67,\ h_{fg\ 500\ kPa} = 2108.47$

$h_4 = 191.81 + 0.78 \times 2392.82 = 2058.21$

To determine the mass flow rates we need the split in the two chambers. The fractions of the vapor output flows equals the quality in the flow right after the valve.

Flash Chamber 1: $\dot{m}_1 h_1 = \dot{m}_3 h_3 + (\dot{m}_1 - \dot{m}_3) h_2$ =>

$$x_{1a} = \dot{m}_3/\dot{m}_1 = (h_1 - h_2)/h_{fg\ 2000\ kPa} = \frac{1085.34 - 908.77}{1890.74} = 0.093387$$

$$\dot{m}_3 = x_{1a}\, \dot{m}_1 = 0.093387 \times 10\ kg/s = \mathbf{0.93387\ kg/s}$$

Flash Chamber 2: $\dot{m}_2 h_2 = \dot{m}_5 h_5 + (\dot{m}_2 - \dot{m}_5) h_6$ =>

$$x_{2a} = \dot{m}_5/\dot{m}_2 = (h_2 - h_6)/h_{fg\ 500\ kPa} = \frac{908.77 - 640.21}{2108.47} = 0.127372$$

$$\dot{m}_5 = x_{2a}\, \dot{m}_2 = 0.127372 \times (10 - 0.93387)\ kg/s = \mathbf{1.15477\ kg/s}$$

CV Turbine. Energy Eq. gives power out put

$$\dot{W}_T = \dot{m}_3 h_3 + \dot{m}_5 h_5 - (\dot{m}_3 + \dot{m}_5) h_4$$
$$= 0.93387 \times 2799.51 + 1.15477 \times 2748.67 - 2.08864 \times 2058.21$$
$$= \mathbf{1489.6\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.29

A smaller power plant produces 25 kg/s steam at 3 MPa, 600°C in the boiler. It cools the condenser with ocean water coming in at 15°C and returned at 18°C so the condenser exit is at 50°C. Find the net power output and the required mass flow rate of ocean water.

Solution:

The states properties from Tables B.1.1 and B.1.3

1: 45°C, x = 0: h_1 = 188.42 kJ/kg, v_1 = 0.00101 m^3/kg, P_{sat} = 9.59 kPa

3: 3.0 MPa, 600°C: h_3 = 3682.34 kJ/kg, s_3 = 7.5084 kJ/kg K

C.V. Pump Reversible and adiabatic.

Energy: $w_p = h_2 - h_1$; Entropy: $s_2 = s_1$

since incompressible it is easier to find work (positive in) as

$w_p = \int v\, dP = v_1 (P_2 - P_1)$ = 0.00101 m^3/kg (3000 - 9.6) kPa = 3.02 kJ/kg

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$

$s_4 = s_3 = 7.5084 = 0.6386 + x_4\,(7.5261)$ => $x_4 = 0.9128$

=> $h_4 = 188.42 + 0.9128\,(2394.77) = 2374.4$ kJ/kg

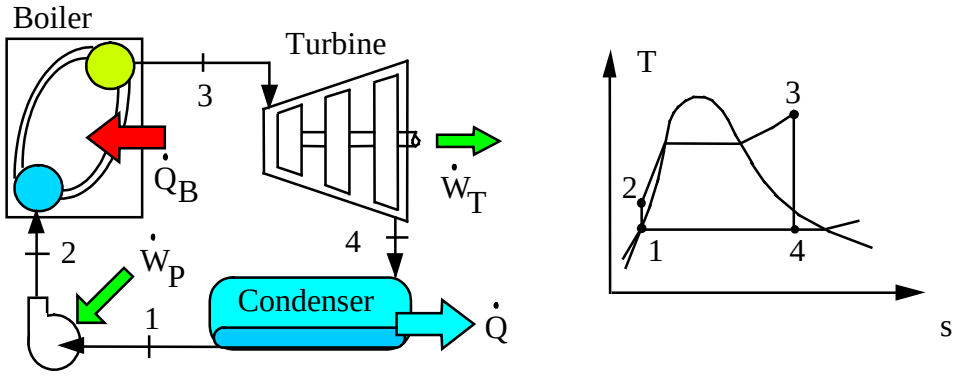
$w_T = 3682.34 - 2374.4 = 1307.94$ kJ/kg

$$\dot{W}_{NET} = \dot{m}(w_T - w_p) = 25\,(1307.94 - 3.02) = \mathbf{32.6\ MW}$$

C.V. Condenser : $q_L = h_4 - h_1 = 2374.4 - 188.42 = 2186$ kJ/kg

$$\dot{Q}_L = \dot{m} q_L = 25 \text{ kg/s} \times 2186 \text{ kJ/kg} = 54.65 \text{ MW} = \dot{m}_{ocean}\, C_p\, \Delta T$$

$$\dot{m}_{ocean} = \dot{Q}_L / C_p\, \Delta T = \frac{54\,650}{4.18 \times (18 - 15)} = \mathbf{4358\ kg/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.30

Consider an ideal Rankine cycle using water with a high-pressure side of the cycle at a supercritical pressure. Such a cycle has a potential advantage of minimizing local temperature differences between the fluids in the steam generator, such as the instance in which the high-temperature energy source is the hot exhaust gas from a gas-turbine engine. Calculate the thermal efficiency of the cycle if the state entering the turbine is 30 MPa, 550°C, and the condenser pressure is 10 kPa. What is the steam quality at the turbine exit?

Solution:

For the efficiency we need the net work and steam generator heat transfer.

C.V. Pump. For this high exit pressure we use Table B.1.4 compressed liquid

State 1: $s_1 = 0.6492$ kJ/kg K, $h_1 = 191.81$ kJ/kg

Entropy Eq.: $s_2 = s_1$ => $h_2 = 222.5$ kJ/kg

$$w_p = h_2 - h_1 = 30.69 \text{ kJ/kg}$$

C.V. Turbine. Assume reversible and adiabatic.

Entropy Eq.: $s_4 = s_3 = 6.0342 = 0.6492 + x_4 \times 7.501$

$$x_4 = \mathbf{0.7179}$$ Very low for a turbine exhaust

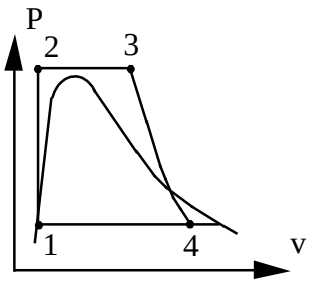
$$h_4 = 191.81 + x_4 \times 2392.82 = 1909.63, \quad h_3 = 3275.36 \text{ kJ/kg}$$

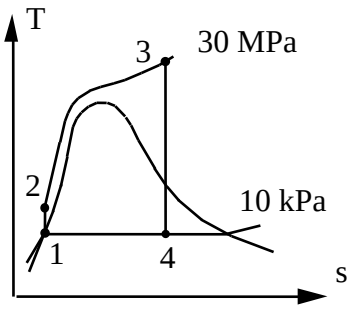
$$w_T = h_3 - h_4 = 1365.7 \text{ kJ/kg}$$

Steam generator: $q_H = h_3 - h_2 = 3052.9$ kJ/kg

$$w_{NET} = w_T - w_p = 1365.7 - 30.69 = 1335 \text{ kJ/kg}$$

$$\eta = w_{NET}/q_H = 1335 / 3052.9 = \mathbf{0.437}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.31

Consider the ammonia Rankine-cycle power plant shown in Fig. P9.31. The plant was designed to operate in a location where the ocean water temperature is 25°C near the surface and 5°C at some greater depth. The mass flow rate of the working fluid is 1000 kg/s.

a. Determine the turbine power output and the pump power input for the cycle.
b. Determine the mass flow rate of water through each heat exchanger.
c. What is the thermal efficiency of this power plant?

Solution:

a) C.V. Turbine. Assume reversible and adiabatic.

$$s_2 = s_1 = 5.0863 = 0.8779 + x_2 \times 4.3269 \quad \Rightarrow \quad x_2 = 0.9726$$

$$h_2 = 227.08 + 0.9726 \times 1225.09 = 1418.6 \text{ kJ/kg}$$

$$w_T = h_1 - h_2 = 1460.29 - 1418.6 = 41.69 \text{ kJ/kg}$$

$$\dot{W}_T = \dot{m} w_T = 1000 \times 41.69 = \mathbf{41\ 690\ kW}$$

Pump: $w_P \approx v_3(P_4 - P_3) = 0.0016(857 - 615) = 0.387$ kJ/kg

$$\dot{W}_P = \dot{m} w_P = 1000 \times 0.387 = \mathbf{387\ kW}$$

b) Consider condenser heat transfer to the low T water

$$\dot{Q}_{\text{to low T H2O}} = 1000(1418.6 - 227.08) = 1.1915 \times 10^6 \text{ kW}$$

$$\dot{m}_{\text{low T H2O}} = \frac{1.1915 \times 10^6}{29.38 - 20.98} = \mathbf{141\ 850\ kg/s}$$

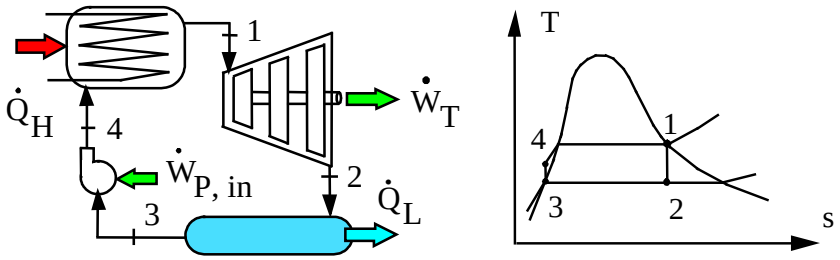
$$h_4 = h_3 + w_P = 227.08 + 0.39 = 227.47 \text{ kJ/kg}$$

Now consider the boiler heat transfer from the high T water

$$\dot{Q}_{\text{from high T H2O}} = 1000(1460.29 - 227.47) = 1.2328 \times 10^6 \text{ kW}$$

$$\dot{m}_{\text{high T H2O}} = \frac{1.2328 \times 10^6}{104.87 - 96.50} = \mathbf{147\ 290\ kg/s}$$

c) $$\eta_{TH} = \dot{W}_{NET}/\dot{Q}_H = \frac{41\ 690 - 387}{1.2328 \times 10^6} = \mathbf{0.033}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.32

Do problem 9.31 with carbon dioxide as the working fluid.

Consider the ammonia Rankine-cycle power plant shown in Fig. P9.31. The plant was designed to operate in a location where the ocean water temperature is 25°C near the surface and 5°C at some greater depth. The mass flow rate of the working fluid is 1000 kg/s.

a. Determine the turbine power output and the pump power input for the cycle.
b. Determine the mass flow rate of water through each heat exchanger.
c. What is the thermal efficiency of this power plant?

a) C.V. Turbine. Assume reversible and adiabatic.

$$s_2 = s_1 = 1.0406 = 0.4228 + x_2 \times 0.6963 \quad \Rightarrow \quad x_2 = 0.88726$$

$$h_2 = 112.83 + 0.88726 \times 197.15 = 287.75 \text{ kJ/kg}$$

$$w_T = h_1 - h_2 = 294.96 - 287.75 = 7.206 \text{ kJ/kg}$$

$$\dot{W}_T = \dot{m} w_T = 1000 \times 7.206 = \mathbf{7\ 206\ kW}$$

Pump: $w_P \approx v_3(P_4 - P_3) = 0.001161(5729 - 4502) = 1.425$ kJ/kg

$$\dot{W}_P = \dot{m} w_P = 1000 \times 1.425 = \mathbf{1425\ kW}$$

b) Consider condenser heat transfer to the low T water

$$\dot{Q}_{\text{to low T H2O}} = 1000(287.75 - 112.83) = 0.2749 \times 10^6 \text{ kW}$$

$$\dot{m}_{\text{low T H2O}} = \frac{0.2749 \times 10^6}{29.38 - 20.98} = \mathbf{32\ 728\ kg/s}$$

$$h_4 = h_3 + w_P = 112.83 + 1.425 = 114.26 \text{ kJ/kg}$$

Now consider the boiler heat transfer from the high T water

$$\dot{Q}_{\text{from high T H2O}} = 1000(294.96 - 114.26) = 0.1807 \times 10^6 \text{ kW}$$

$$\dot{m}_{\text{high T H2O}} = \frac{0.1807 \times 10^6}{104.87 - 96.50} = \mathbf{21\ 589\ kg/s}$$

c) $$\eta_{TH} = \dot{W}_{NET}/\dot{Q}_H = \frac{7\ 206 - 1425}{0.1807 \times 10^6} = \mathbf{0.032}$$

Reheat Cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.33

The power plant in problem 9.16 has a too low quality in the low pressure turbine section so the plant wants to apply reheat at 800 kPa. What should the superheat for the reheat be so the turbine quality stays above 92%.

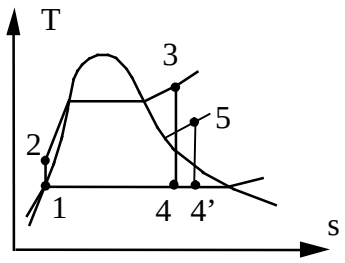
The reheat cycle has expansion in the turbine from state 3 to 800 kPa then reheat to state 5 and then expansion in the turbine to the new exhaust state 4'. We can then relate states 4' and 5 as follows

C.V. Turbine : $w_{T2} = h_5 - h_{4'}$; $s_{4'} = s_5$ and $x_{4'} = 0.92$

$$s_{4'} = s_5 = 0.8311 + x_{4'}\,(7.0784) = 7.34323 \text{ kJ/kgK}$$

State 5: 800 kPa, s = 7.34323 kJ/kgK => From Table B.1.3 at 800 kPa

$$T_5 = 300 + 50\,\frac{7.34323 - 7.2327}{7.4088 - 7.2327} = \mathbf{331.4^oC}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.34

Consider the supercritical cycle in problem 9.30 and assume the turbine first expands to 3 MPa then a reheat to 500^{o}C with a further expansion in the low pressure turbine to 10 kPa. Find the combined specific turbine work and the total specific heat transfer in the boiler.

For the efficiency we need the net work and steam generator heat transfer.

C.V. Pump. For this high exit pressure we use Table B.1.4

State 1: $s_1 = 0.6492$ kJ/kg K, $h_1 = 191.81$ kJ/kg

Entropy Eq.: $s_2 = s_1$ => $h_2 = 222.5$ kJ/kg

State 3: $h_3 = 3275.36$ kJ/kg, $s_3 = 6.0342$ kJ/kg-K

C.V. Turbine section 1. Assume reversible and adiabatic.

Entropy Eq.: $s_4 = s_3 = 6.0342 = 2.6456 + x_4 \times 3.5412$, $x_4 = 0.956907$

$h_4 = 1008.41 + x_4 \times 1795.73 = 2726.76$ kJ/kg,

State 5: $h_5 = 3456.48$ kJ/kg, $s_5 = 7.2337$ kJ/kg-K

C.V. Turbine section 2. Assume reversible and adiabatic.

Entropy Eq.: $s_6 = s_5 = 7.2337 = 0.6492 + x_6 \times 7.501$, $x_6 = 0.87782$

$h_6 = 191.81 + x_6 \times 2392.82 = 2292.27$ kJ/kg

Steam generator: $q_H = h_3 - h_2 + h_5 - h_4$

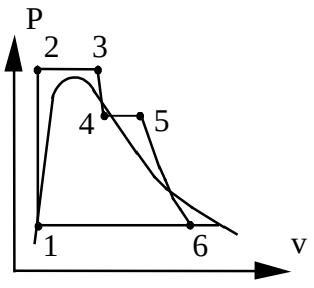
$= 3275.36 - 222.5 + 3456.48 - 2726.76$

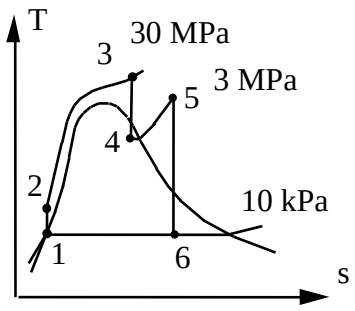
$= 3052.86 + 729.72 =$ **3782.6 kJ/kg**

Turbine: $w_T = h_3 - h_4 + h_5 - h_6$

$= 3275.36 - 2726.76 + 3456.48 - 2292.27$

$= 548.6 + 1164.21 =$ **1712.8 kJ/kg**

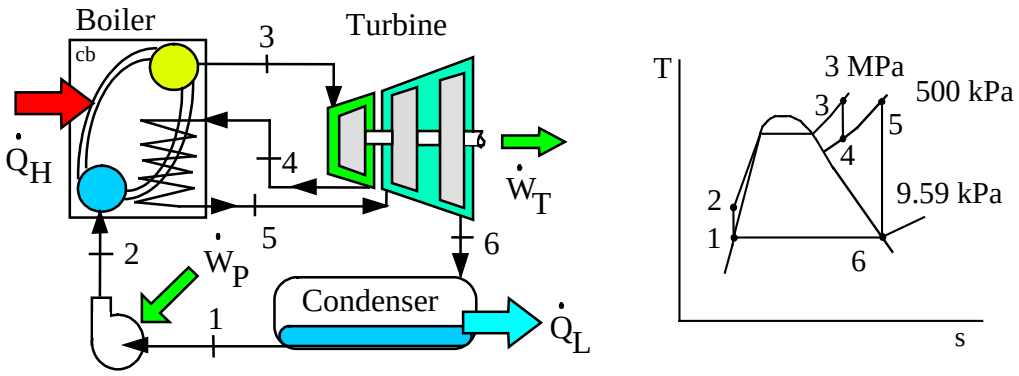




Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.35

A smaller power plant produces steam at 3 MPa, 600°C in the boiler. It keeps the condenser at 45°C by transfer of 10 MW out as heat transfer. The first turbine section expands to 500 kPa and then flow is reheated followed by the expansion in the low pressure turbine. Find the reheat temperature so the turbine output is saturated vapor. For this reheat find the total turbine power output and the boiler heat transfer.



The states properties from Tables B.1.1 and B.1.3

1: 45°C, x = 0: h_1 = 188.42 kJ/kg, v_1 = 0.00101 m^3/kg, P_{sat} = 9.59 kPa

3: 3.0 MPa, 600°C: h_3 = 3682.34 kJ/kg, s_3 = 7.5084 kJ/kg K

6: 45°C, x = 1: h_6 = 2583.19 kJ/kg, s_6 = 8.1647 kJ/kg K

C.V. Pump Reversible and adiabatic.

Energy: $w_p = h_2 - h_1$; Entropy: $s_2 = s_1$

since incompressible it is easier to find work (positive in) as

$w_p = \int v\, dP = v_1 (P_2 - P_1) = 0.00101\ (3000 - 9.59) = 3.02$ kJ/kg

$h_2 = h_1 + w_p = 188.42 + 3.02 = 191.44$ kJ/kg

C.V. HP Turbine section

Entropy Eq.: $s_4 = s_3$ => h_4 = 3093.26 kJ/kg; T_4 = 314°C

C.V. LP Turbine section

Entropy Eq.: $s_6 = s_5 = 8.1647$ kJ/kg K => state 5

State 5: 500 kPa, s_5 => h_5 = 3547.55 kJ/kg, T_5 = **529°C**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

C.V. Condenser.

Energy Eq.: $q_L = h_6 - h_1 = h_{fg} = 2394.77$ kJ/kg

$$\dot{m} = \dot{Q}_L / q_L = 10\ 000 / 2394.77 = 4.176 \text{ kg/s}$$

Both turbine sections

$$\dot{W}_{T,tot} = \dot{m} w_{T,tot} = \dot{m}(h_3 - h_4 + h_5 - h_6)$$

$$= 4.176\ (3682.34 - 3093.26 + 3547.55 - 2583.19) = \mathbf{6487\ kW}$$

Both boiler sections

$$\dot{Q}_H = \dot{m}(h_3 - h_2 + h_5 - h_4)$$

$$= 4.176\ (3682.34 - 191.44 + 3547.55 - 3093.26) = \mathbf{16\ 475\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.36

A smaller power plant produces 25 kg/s steam at 3 MPa, 600°C in the boiler. It cools the condenser with ocean water so the condenser exit is at 50°C. There is a reheat done at 500 kPa up to 400°C and then expansion in the low pressure turbine. Find the net power output and the total heat transfer in the boiler.

Solution:

The states properties from Tables B.1.1 and B.1.3

1: 50°C, x = 0, h_1 = 209.31 kJ/kg, v_1 = 0.001012 m^3/kg, P_{sat} = 12.35 kPa

3: 3.0 MPa, 600°C: h_3 = 3682.34 kJ/kg, s_3 = 7.5084 kJ/kg K

5: 500 kPa, 400°C: h_5 = 3271.83 kJ/kg, s_5 = 7.7937 kJ/kg K

C.V. Pump Reversible and adiabatic. Incompressible flow so

Energy: $w_p = h_2 - h_1 = v_1(P_2 - P_1) = 0.001012\ (3000 - 12.35) = 3.02$ kJ/kg

C.V. LP Turbine section

Entropy Eq.: $s_6 = s_5 = 7.7937$ kJ/kg K => two-phase state

$$x_6 = (s_6 - s_f)/s_{fg} = \frac{7.7937 - 0.7037}{7.3725} = 0.9617$$

$$h_6 = 209.31 + 0.9617 \times 2382.75 = 2500.8 \text{ kJ/kg}$$

Both turbine sections

$w_{T,tot} = h_3 - h_4 + h_5 - h_6$

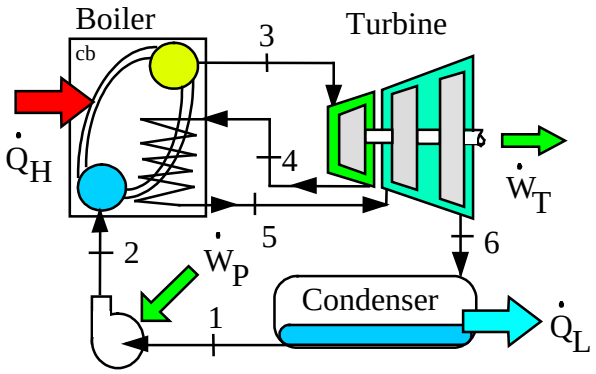
$= 3682.34 - 3093.26 + 3271.83 - 2500.8 = 1360.11$ kJ/kg

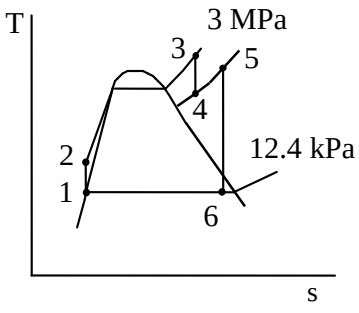
$\dot{W}_{net} = \dot{W}_T - \dot{W}_p = \dot{m}(w_{T,tot} - w_p) = 25\ (1360.11 - 3.02) =$ **33 927 kW**

Both boiler sections

$\dot{Q}_H = \dot{m}(h_3 - h_2 + h_5 - h_4)$

$= 25\ (3682.34 - 191.44 + 3271.83 - 3093.26) =$ **91 737 kW**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.37

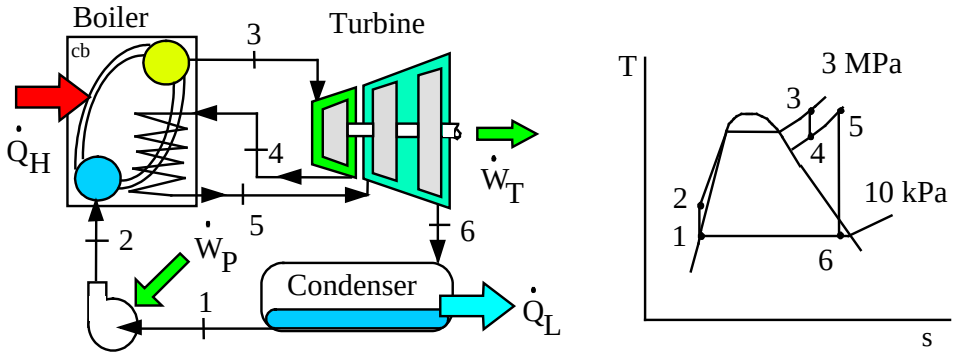
Consider an ideal steam reheat cycle where steam enters the high-pressure turbine at 3.0 MPa, 400°C, and then expands to 0.8 MPa. It is then reheated to 400°C and expands to 10 kPa in the low-pressure turbine. Calculate the cycle thermal efficiency and the moisture content of the steam leaving the low-pressure turbine.

Solution:

C.V. Pump reversible, adiabatic and assume incompressible flow

$w_P = v_1(P_2 - P_1) = 0.00101\ m^3/kg \times (3000 - 10)\ kPa = 3.02\ kJ/kg,$

$h_2 = h_1 + w_P = 191.81 + 3.02 = 194.83\ kJ/kg$



C.V. HP Turbine section

$P_3 = 3$ MPa, $T_3 = 400^oC$ => $h_3 = 3230.82$ kJ/kg, $s_3 = 6.9211$ kJ/kg K

$s_4 = s_3$ => $h_4 = 2891.6$ kJ/kg;

C.V. LP Turbine section

State 5: 400^oC, 0.8 MPa => $h_5 = 3267.1$ kJ/kg, $s_5 = 7.5715$ kJ/kg K

Entropy Eq.: $s_6 = s_5 = 7.5715$ kJ/kg K => two-phase state

$$x_6 = \frac{s_6 - s_f}{s_{fg}} = \frac{7.5715 - 0.6492}{7.501} = 0.92285 = \mathbf{0.923}$$

$h_6 = 191.81 + 0.92285 \times 2392.82 = 2400$ kJ/kg

$w_{T,tot} = h_3 - h_4 + h_5 - h_6 = 3230.82 - 2891.6 + 3267.1 - 2400 = 1237.8$ kJ/kg

$q_{H1} = h_3 - h_2 = 3230.82 - 194.83 = 3036$ kJ/kg

$q_H = q_{H1} + h_5 - h_4 = 3036 + 3267.1 - 2891.6 = 3411.5$ kJ/kg

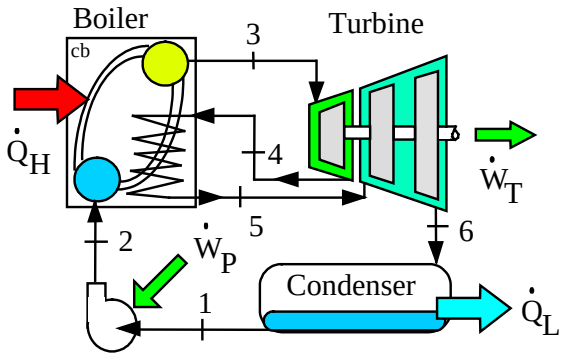
$\eta_{CYCLE} = (w_{T,tot} - w_P)/q_H = (1237.8 - 3.02)/3411.5 = \mathbf{0.362}$

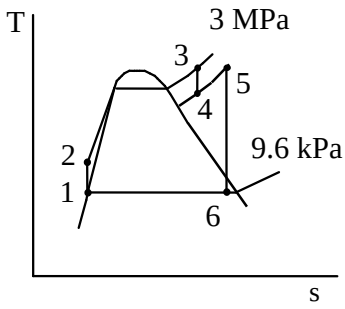
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.38

The reheat pressure affects the operating variables and thus turbine performance. Repeat Problem 9.35 twice, using 0.6 and 1.0 MPa for the reheat pressure.

Solution





C.V. Pump reversible, adiabatic and assume incompressible flow

$w_P = v_1(P_2 - P_1) = 0.00101\ m^3/kg \times (3000 - 9.59)\ kPa = 3.02\ kJ/kg,$

$h_2 = h_1 + w_P = 188.42 + 3.02 = 191.44\ kJ/kg$

State 3: 3 MPa, 400°C => $h_3 = 3230.82$ kJ/kg, $s_3 = 6.9211$ kJ/kg K

Low T boiler section: $q_{H1} = h_3 - h_2 = 3230.82 - 191.44 = 3039.38$ kJ/kg

State 4: P_4, $s_4 = s_3$

For $P_4 = 1$ MPa: $h_4 = 2940.85$ kJ/kg state 4 is sup. vapor

State 5: 400°C, $P_5 = P_4$ => $h_5 = 3263.9$ kJ/kg, $s_5 = 7.465$ kJ/kg K,

For $P_4 = 0.6$ MPa: $h_4 = 2793.2$ kJ/kg state 4 is sup. vapor

State 5: 400°C, $P_5 = P_4$ => $h_5 = 3270.3$ kJ/kg, $s_5 = 7.7078$ kJ/kg K,

State 6: 45°C, $s_6 = s_5$ => $x_6 = (s_6 - s_f)/s_{fg}$

Total turbine work: $w_{T,tot} = h_3 - h_4 + h_5 - h_6$

Total boiler H.Tr.: $q_H = q_{H1} + h_5 - h_4$

Cycle efficiency: $\eta_{CYCLE} = (w_{T,tot} - w_P)/q_H$

$P_4=P_5$	x_6	h_6	w_T	q_H	η_{CYCLE}
1	0.907	2360.5	1193.4	3362.4	0.3540
0.6	0.9393	2437.8	1270.1	3516.5	0.3603

Notice the small change in efficiency.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.39

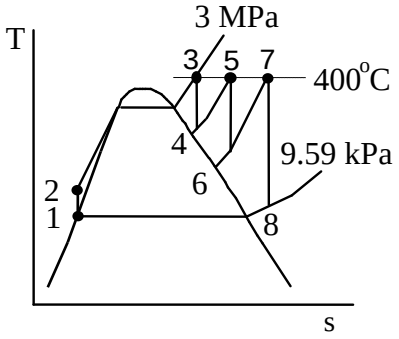
The effect of a number of reheat stages on the ideal steam reheat cycle is to be studied. Repeat Problem 9.35 using two reheat stages, one stage at 1.2 MPa and the second at 0.2 MPa, instead of the single reheat stage at 0.8 MPa.

C.V. Pump reversible, adiabatic and assume incompressible flow, work in

$w_P = v_1(P_2 - P_1) = 0.00101\ m^3/kg \times (3000 - 9.593)\ kPa = 3.02\ kJ/kg,$

$h_2 = h_1 + w_P = 188.42 + 3.02 = 191.44\ kJ/kg$

$P_4 = P_5 = 1.2\ MPa,\ P_6 = P_7 = 0.2\ MPa$



3: $h_3 = 3230.82\ kJ/kg,\ s_3 = 6.9211\ kJ/kg\ K$

4: $P_4, s_4 = s_3 \Rightarrow$ sup. vap. $h_4 = 2985.3$

5: $h_5 = 3260.7\ kJ/kg,\ s_5 = 7.3773\ kJ/kg\ K$

6: $P_6, s_6 = s_5 \Rightarrow$ sup. vapor

$h_6 = 2811.2\ kJ/kg$

7: $h_7 = 3276.5\ kJ/kg,\ s_7 = 8.2217\ kJ/kg\ K$

8: $P_8, s_8 = s_7 \Rightarrow$ sup. vapor $h_8 = 2602\ kJ/kg$ (used CATT3)

Total turbine work, same flow rate through all sections

$w_T = (h_3 - h_4) + (h_5 - h_6) + (h_7 - h_8) = 245.5 + 449.5 + 674.5 = 1369.5\ kJ/kg$

Total heat transfer in boiler, same flow rate through all sections

$q_H = (h_3 - h_2) + (h_5 - h_4) + (h_7 - h_6) = 3039 + 319.8 + 465.3 = 3824.5\ kJ/kg$

Cycle efficiency: $\eta_{TH} = \dfrac{w_T - w_P}{q_H} = \dfrac{1369.5 - 3.02}{3824.5} = \mathbf{0.357}$

Open Feedwater Heaters

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.40

An open FWH receives steam at 1 MPa, 200^{o}C from the turbine and 1 MPa, 100^{o} C water from the feed water line. Find the required fraction of the extraction flow in the turbine.

The setup follows Fig.9.12

State enthalpies: $h_2 = 419.02$, $h_6 = 2827.86$ all kJ/kg

$h_3 = 762.79$ (x = 0 at 1 MPa)

Analyze the FWH which leads to Eq.9.5:

$y = \dot{m}_6 / \dot{m}_5$ the extraction fraction

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{762.79 - 419.02}{2827.86 - 419.02} = \mathbf{0.1427}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.41

A power plant for a polar expedition uses ammonia and the boiler exit is 80°C, 1000 kPa and the condenser operates at -15°C. A single open "feed water" heater operates at 400 kPa with an exit state of saturated liquid. Find the mass fraction extracted in the turbine.

CV Feedwater heater.

States given and fixed from knowing Fig. 9.12:

5: $h_5 = 1614.6$ kJ/kg, $s_5 = 5.4971$ kJ/kgK

3: $h_3 = 171.226$ kJ/kg

1: $h_1 = 111.66$ kJ/kg, $v_1 = 0.001519$ m^3/kg

Analyze the pump: $h_2 = h_1 + w_{P1} = h_1 + v_1 (P_2 - P_1)$

$= 111.66 + 0.001519$ m^3/kg $\times$ (400 – 236.3) kPa

$= 111.91$ kJ/kg

Analyze the turbine: 6: 400 kPa, $s_6 = s_1$ => $h_6 = 1479.6$ kJ/kg

Analyze the FWH leads to Eq.9.5:

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{171.226 - 111.91}{1479.6 - 111.91} = \mathbf{0.0401}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.42

Find the cycle efficiency for the cycle in Problem 9.41
CV Feedwater heater.

States given and fixed from knowing Fig. 9.12:

5: $h_5 = 1614.6$ kJ/kg, $s_5 = 5.4971$ kJ/kgK

3: $h_3 = 171.226$ kJ/kg

1: $h_1 = 111.66$ kJ/kg, $v_1 = 0.001519$ m^3/kg

Analyze the pump: $w_{P1} = v_1 (P_2 - P_1) = 0.001519$ m^3/kg $\times$ (400 – 236.3) kPa
$= 0.249$ kJ/kg

$h_2 = h_1 + w_{P1} = 111.66 + 0.249 = 111.909$ kJ/kg

Analyze the turbine: 6: 400 kPa, $s_6 = s_5$ => $h_6 = 1479.6$ kJ/kg

7: -15 C, $s_7 = s_5$ => $h_7 = 1413.56$ kJ/kg

Analyze the FWH leads to Eq.9.5:

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{171.226 - 111.909}{1479.6 - 11.909} = 0.0434$$

$w_T = h_5 - y\, h_6 - (1 - y)\, h_7$
$= 1614.6 - 0.0434 \times 1479.6 - (1 - 0.0434) \times 1413.56$
$= 198.15$ kJ/kg

Pump 2 gives: $w_{P2} = v_3 (P_4 - P_3) = 0.00156$ m^3/kg $\times$ (1000 – 400) kPa
$= 0.936$ kJ/kg

Net work: $w_{net} = w_T - w_{P2} - (1 - y)\, w_{P1} = 198.15 - 0.936 - (1\text{-}0.0434)\ 0.249$
$= 196.98$ kJ/kg

Boiler: $q_H = h_5 - h_4 = h_5 - (h_3 + w_{P2}) = 1614.6 - 171.65 - 0.936$
$= 1442$ kJ/kg

Cycle efficiency: $\eta = w_{net} / q_H = 196.98 / 1442 =$ **0.1366**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.43

A steam power plant has high and low pressures of 20 MPa and 10 kPa, and one open feedwater heater operating at 1 MPa with the exit as saturated liquid. The maximum temperature is 800°C and the turbine has a total power output of 5 MW. Find the fraction of the flow for extraction to the feedwater and the total condenser heat transfer rate.

The physical components and the T-s diagram is as shown in Fig. 9.12 in the main text for one open feedwater heater. The same state numbering is used. From the Steam Tables:

State 5: (P, T) $h_5 = 4069.8$ kJ/kg, $s_5 = 7.0544$ kJ/kg K,

State 1: (P, x = 0) $h_1 = 191.81$ kJ/kg, $v_1 = 0.00101$ m^3/kg

State 3: (P, x = 0) $h_3 = 762.8$ kJ/kg, $v_3 = 0.001127$ m^3/kg

Pump P1: $w_{P1} = v_1(P_2 - P_1) = 0.00101 \times 990 = 1$ kJ/kg

$h_2 = h_1 + w_{P1} = 192.81$ kJ/kg

Turbine 5-6: $s_6 = s_5 \Rightarrow h_6 = 3013.7$ kJ/kg

$w_{T56} = h_5 - h_6 = 4069.8 - 3013.7 = 1056.1$ kJ/kg

Feedwater Heater ($\dot{m}_{TOT} = \dot{m}_5$): $y\,\dot{m}_5 h_6 + (1 - y)\,\dot{m}_5 h_2 = \dot{m}_5 h_3$

$$\Rightarrow \quad y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{762.8 - 192.81}{3013.7 - 192.81} = \mathbf{0.2021}$$

To get state 7 into condenser consider turbine.

$s_7 = s_6 = s_5 \quad \Rightarrow \quad x_7 = (7.0544 - 0.6493)/7.5009 = 0.85391$

$h_7 = 191.81 + 0.85391 \times 2392.82 = 2235.1$ kJ/kg

Find specific turbine work to get total flow rate

$$\dot{W}_T = \dot{m}_{TOT} h_5 - y\dot{m}_{TOT} h_6 - (1 - y)\dot{m}_{TOT} h_7 =$$

$$= \dot{m}_{TOT} \times [h_5 - yh_6 - (1 - y)\, h_7] = \dot{m}_{TOT} \times 1677.3$$

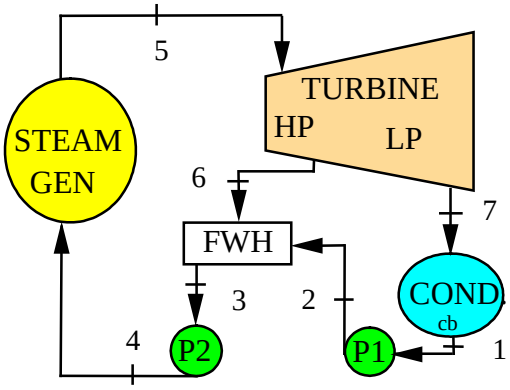
$$\dot{m}_{TOT} = 5000/1677.3 = 2.98 \text{ kg/s}$$

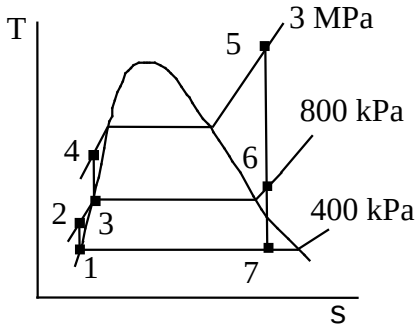
$$\dot{Q}_L = \dot{m}_{TOT}\,(1\text{-}y)\,(h_7\text{-}h_1) = 2.98 \times 0.7979(2235.1 - 191.81) = \mathbf{4858\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.44

A low temperature power plant operates with R-410A maintaining -20°C in the condenser, a high pressure of 3 MPa with superheat to 80°C. There is one open "feed water" heater operating at 800 kPa with an exit as saturated liquid at 0°C. Find the extraction fraction of the flow out of the turbine and the turbine work per unit mass flowing through the boiler.





State 1: $x_1 = 0$, $h_1 = 28.24$ kJ/kg, $v_1 = 0.000803$ m^3/kg

State 3: $x_3 = 0$, $h_3 = 57.76$ kJ/kg, $v_3 = 0.000855$ m^3/kg

State 5: $h_5 = 329.1$ kJ/kg, $s_5 = 1.0762$ kJ/kg K

State 6: $s_6 = s_5$ => $T_6 = 10.2$°C, $h_6 = 290.3$ kJ/kg

State 7: $s_7 = s_5$ => $x_7 = (s_7 - s_f)/s_{fg} = 0.9982$, $h_7 = 271.5$ kJ/kg

C.V Pump P1

$$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.000803\ (800 - 400) = 0.32 \text{ kJ/kg}$$

$$\Rightarrow\ h_2 = h_1 + w_{P1} = 28.24 + 0.32 = 28.56 \text{ kJ/kg}$$

C.V. Feedwater heater: Call $\dot{m}_6 / \dot{m}_{tot} = y$ (the extraction fraction)

Energy Eq.: $(1 - y)\, h_2 + y\, h_6 = 1\, h_3$

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{57.76 - 28.56}{290.3 - 28.56} = \mathbf{0.1116}$$

C.V. Turbine

$$\dot{W}_T = \dot{m}_{TOT}\, h_5 - y\, \dot{m}_{TOT}\, h_6 - (1 - y)\, \dot{m}_{TOT}\, h_7$$

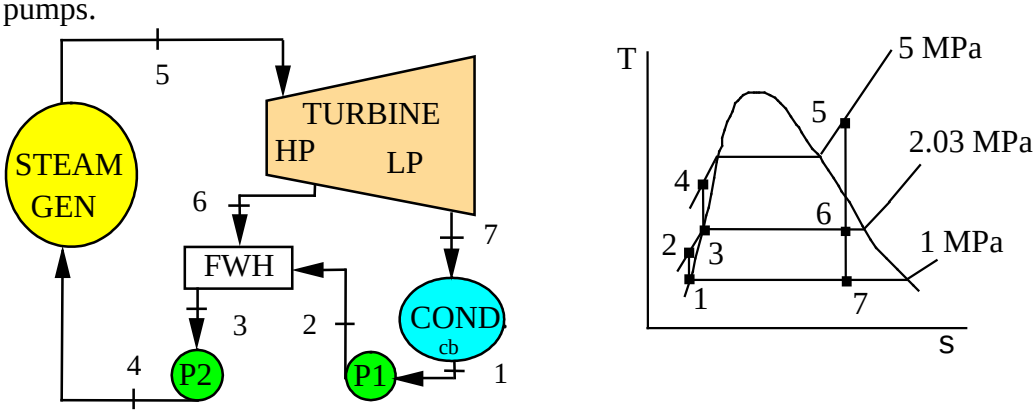
$$w_T = h_5 - y\, h_6 - (1 - y)\, h_7$$

$$= 329.1 - 0.1116 \times 290.3 - (1 - 0.1116) \times 271.5 = \mathbf{55.52 \text{ kJ/kg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.45

A Rankine cycle operating with ammonia is heated by some low temperature source so the highest T is 120°C at a pressure of 5000 kPa. Its low pressure is 1003 kPa and it operates with one open feedwater heater at 2033 kPa. The total flow rate is 5 kg/s. Find the extraction flow rate to the feedwater heater assuming its outlet state is saturated liquid at 2033 kPa. Find the total power to the two pumps.



State 1: $x_1 = 0$, $h_1 = 298.25$ kJ/kg, $v_1 = 0.001658$ m^3/kg

State 3: $x_3 = 0$, $h_3 = 421.48$ kJ/kg, $v_3 = 0.001777$ m^3/kg

State 5: $h_5 = 421.48$ kJ/kg, $s_5 = 4.7306$ kJ/kg K

State 6: $s_6 = s_5$ => $x_6 = (s_6 - s_f)/s_{fg} = 0.99052$, $h_6 = 1461.53$ kJ/kg

C.V Pump P1

$$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.001658(2033 - 1003) = 1.708 \text{ kJ/kg}$$

$$\Rightarrow h_2 = h_1 + w_{P1} = 298.25 + 1.708 = 299.96 \text{ kJ/kg}$$

C.V. Feedwater heater: Call $\dot{m}_6 / \dot{m}_{tot} = y$ (the extraction fraction)

Energy Eq.: $(1 - y)\, h_2 + y\, h_6 = 1\, h_3$

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{421.48 - 299.96}{1461.53 - 299.96} = \mathbf{0.1046}$$

$$\dot{m}_{extr} = y\, \dot{m}_{tot} = 0.1046 \times 5 = \mathbf{0.523 \text{ kg/s}}$$

$$\dot{m}_1 = (1 - y)\, \dot{m}_{tot} = (1 - 0.1046)\, 5 = 4.477 \text{ kg/s}$$

C.V Pump P2

$$w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.001777\ (5000 - 2033) = 5.272 \text{ kJ/kg}$$

Total pump work

$$\dot{W}_p = \dot{m}_1 w_{P1} + \dot{m}_{tot}\, w_{P2} = 4.477 \times 1.708 + 5 \times 5.272 = \mathbf{34 \text{ kW}}$$

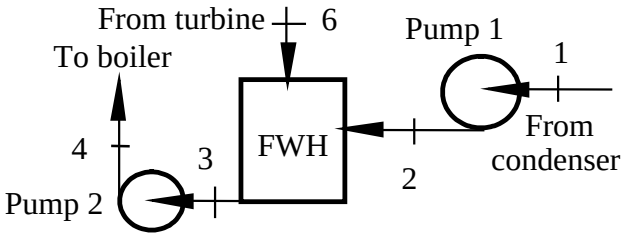
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.46

A power plant with one open feedwater heater has a condenser temperature of 45°C, a maximum pressure of 5 MPa, and boiler exit temperature of 900°C. Extraction steam at 1 MPa to the feedwater heater is mixed with the feedwater line so the exit is saturated liquid into the second pump. Find the fraction of extraction steam flow, the two specific pump work inputs and the turbine work per unit mass flow in the boiler.

Solution:

The complete diagram is as in Figure 9.12 in the main text.



State out of boiler 5: $h_5 = 4378.82$ kJ/kg, $s_5 = 7.9593$ kJ/kg K

C.V. Turbine reversible, adiabatic: $s_7 = s_6 = s_5$

State 6: P_6 , s_6 => $h_6 = 3640.6$ kJ/kg, $T_6 = 574^oC$

State 7: $s_7 = s_5$ => $x_7 = (s_7 - s_f)/s_{fg} = 0.97271$, $h_7 = 2517.84$ kJ/kg

C.V Pump P1

$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.00101(1000 - 9.6) =$ **1.0 kJ/kg**

=> $h_2 = h_1 + w_{P1} = 188.42 + 1.0 = 189.42$ kJ/kg

C.V. Feedwater heater: Call $\dot{m}_6 / \dot{m}_{tot} = y$ (the extraction fraction)

Energy Eq.: $(1 - y)\, h_2 + y\, h_6 = 1\, h_3$

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{762.79 - 189.42}{3640.6 - 189.42} = \mathbf{0.1661}$$

C.V Pump P2

$w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.001127(5000 - 1000) =$ **4.5 kJ/kg**

C.V. Turbine

$$\dot{W}_T = \dot{m}_{TOT}\, h_5 - y\, \dot{m}_{TOT}\, h_6 - (1 - y)\, \dot{m}_{TOT}\, h_7$$

$$w_T = h_5 - y\, h_6 - (1 - y)\, h_7$$

$$= 4378.82 - 0.1661 \times 3640.6 - (1 - 0.1661) \times 2517.84$$

$$= \mathbf{1674.5\ kJ/kg}$$

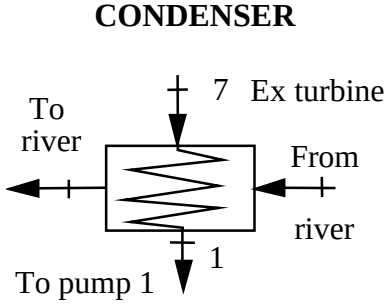
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.47

A steam power plant operates with a boiler output of 20 kg/s steam at 2 MPa, 600°C. The condenser operates at 50°C dumping energy to a river that has an average temperature of 20°C. There is one open feedwater heater with extraction from the turbine at 600 kPa and its exit is saturated liquid. Find the mass flow rate of the extraction flow. If the river water should not be heated more than 5°C how much water should be pumped from the river to the heat exchanger (condenser)?

Solution:

The setup is as shown in Fig. 9.12.



1: 50°C sat liq. $v_1 = 0.001012$ m^3/kg,

$h_1 = 209.31$ kJ/kg

2: 600 kPa $s_2 = s_1$

3: 600 kPa, sat liq. $h_3 = h_f = 670.54$ kJ/kg

5: (P, T) $h_5 = 3690.1$ kJ/kg,

$s_5 = 7.7023$ kJ/kg K

6: 600 kPa, $s_6 = s_5$ => $h_6 = 3270.0$ kJ/kg

CV P1

$$w_{P1} = v_1(P_2 - P_1) = 0.001012 \text{ m}^3\text{/kg } (600 - 12.35) \text{ kPa} = 0.595 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{P1} = 209.9 \text{ kJ/kg}$$

C.V FWH

$$y\, h_6 + (1 - y)\, h_2 = h_3$$

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{670.54 - 209.9}{3270.0 - 209.9} = 0.1505$$

$$\dot{m}_6 = y\, \dot{m}_5 = 0.1505 \times 20 = \mathbf{3 \text{ kg/s}}$$

CV Turbine: $s_7 = s_6 = s_5$ => $x_7 = 0.9493$, $h_7 = 2471.17$ kJ/kg

CV Condenser

$$q_L = h_7 - h_1 = 2471.17 - 209.31 = 2261.86 \text{ kJ/kg}$$

The heat transfer out of the water from 7 to 1 goes into the river water

$$\dot{Q}_L = (1 - y)\, \dot{m} q_L = 0.85 \times 20 \times 2261.86 = 38\,429 \text{ kW}$$

$$= \dot{m}_{H2O}\, \Delta h_{H2O} = \dot{m}_{H2O}\, (h_{f25} - h_{f20}) = \dot{m}\, (20.93)$$

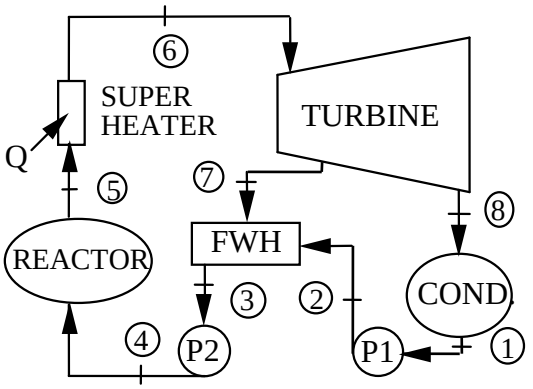
$$\dot{m} = 38\,429 / 20.93 = \mathbf{1836 \text{ kg/s}}$$

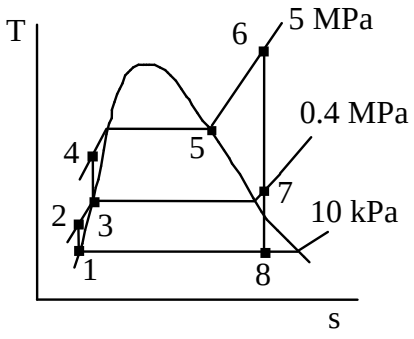
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.48

In one type of nuclear power plant, heat is transferred in the nuclear reactor to liquid sodium. The liquid sodium is then pumped through a heat exchanger where heat is transferred to boiling water. Saturated vapor steam at 5 MPa exits this heat exchanger and is then superheated to 600°C in an external gas-fired superheater. The steam enters the turbine, which has one (open-type) feedwater extraction at 0.4 MPa. The condenser pressure is 10 kPa. Determine the heat transfer in the reactor and in the superheater to produce a net power output of 5 MW.

Solution:
The complete cycle diagram is similar to Figure 9.12 except the boiler is separated into a section heated by the reactor and a super heater section.





CV. Pump P1

$$w_{P1} = 0.001008(400 - 7.5) = 0.4 \text{ kJ/kg} ;$$

$$h_2 = h_1 + w_{P1} = 168.8 + 0.4 = 169.2 \text{ kJ/kg}$$

CV. Pump P2

$$w_{P2} = 0.001084(5000 - 400) = 5.0 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{P2} = 604.7 + 5.0 = 609.7 \text{ kJ/kg}$$

C.V. Turbine (to get exit state properties)

$$s_7 = s_6 = 7.2589, \quad P_7 = 0.4 \text{ MPa} \Rightarrow \quad T_7 = 221.2^{o}\text{C}, \quad h_7 = 2904.5 \text{ kJ/kg}$$

$$s_8 = s_6 = 7.2589 = 0.6492 + x_8 \times 7.501 \qquad x_8 = 0.88118$$

$$h_8 = 191.81 + 0.88118 \times 2392.82 = 2300.3 \text{ kJ/kg}$$

CV: Feedwater heater FWH (to get the extraction fraction x_7)

Divide the equations with the total mass flow rate $\dot{m}_3 = \dot{m}_4 = \dot{m}_5 = \dot{m}_6$

Continuity: $x_2 + x_7 = x_3 = 1.0$, Energy Eq.: $x_2 h_2 + x_7 h_7 = h_3$

$$x_7 = (604.7\text{-}169.2)/(2904.5\text{-}169.2) = 0.1592$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

CV: Turbine (to get the total specific work)

Full flow from 6 to 7 and the fraction $(1 - x_7)$ from 7 to 8.

$$w_T = (h_6 - h_7) + (1 - x_7)(h_7 - h_8)$$

$$= 3666.5\text{-}2904.5 + 0.8408(2904.5\text{-}2300.3) = 1270.0 \text{ kJ/kg}$$

CV: Pumps (P1 has $x_1 = 1 - x_7$, P2 has the full flow $x_3 = 1$)

$$w_P = x_1 w_{P1} + x_3 w_{P2} = 0.8408 \times 0.4 + 1 \times 5.0 = 5.3 \text{ kJ/kg}$$

$$w_{NET} = 1270.0 - 5.3 = 1264.7 \quad \Rightarrow \quad \dot{m} = 5000/1264.7 = 3.954 \text{ kg/s}$$

CV: Reactor (this has the full flow)

$$\dot{Q}_{REACT} = \dot{m}(h_5 - h_4) = 3.954\ (2794.3 - 609.7) = \mathbf{8638\ kW}$$

CV: Superheater (this has the full flow)

$$\dot{Q}_{SUP} = \dot{m}(h_6 - h_5) = 3.954\ (3666.5 - 2794.3) = \mathbf{3449\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.49

Consider an ideal steam regenerative cycle in which steam enters the turbine at 3.0 MPa, 400°C, and exhausts to the condenser at 10 kPa. Steam is extracted from the turbine at 0.8 MPa for an open feedwater heater. The feedwater leaves the heater as saturated liquid. The appropriate pumps are used for the water leaving the condenser and the feedwater heater. Calculate the thermal efficiency of the cycle and the net work per kilogram of steam.

Solution:

This is a standard Rankine cycle with an open FWH as shown in Fig.9.12

C.V Pump P1

$$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.00101(800 - 10) = 0.798 \text{ kJ/kg}$$

$$\Rightarrow \; h_2 = h_1 + w_{P1} = 191.81 + 0.798 = 192.61 \text{ kJ/kg}$$

C.V. FWH Call $\dot{m}_6 / \dot{m}_{tot} = y$ (the extraction fraction)

$$(1 - y)\, h_2 + y\, h_6 = 1\, h_3$$

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{721.1 - 192.61}{2891.6 - 192.61} = 0.1958$$

C.V Pump P2

$$w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.001115(3000 - 800) = 2.45 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{P2} = 721.1 + 2.45 = 723.55 \text{ kJ/kg}$$

CV Boiler: $q_H = h_5 - h_4 = 3230.82 - 723.55 = 2507.3$ kJ/kg

CV Turbine

Entropy Eq.: $s_7 = s_6 = s_5 = 6.9211$ kJ/kg K

P_6 , s_6 => $h_6 = 2891.6$ kJ/kg (superheated vapor)

$$s_7 = s_6 = s_5 = 6.9211 \quad \Rightarrow \quad x_7 = \frac{6.9211 - 0.6492}{7.501} = 0.83614$$

$$\Rightarrow \quad h_7 = 191.81 + x_7\, 2392.82 = 2192.55 \text{ kJ/kg}$$

Turbine has full flow in HP section and fraction 1-y in LP section

$$\dot{W}_T / \dot{m}_5 = h_5 - h_6 + (1 - y)(h_6 - h_7)$$

$$w_T = 3230.82 - 2891.6 + (1 - 0.1988)(2891.6 - 2192.55) = 899.3 \text{ kJ/kg}$$

P2 has the full flow and P1 has the fraction 1-y of the flow

$$w_{net} = w_T - (1 - y)\, w_{P1} - w_{P2}$$

$$= 899.3 - (1 - 0.1988)0.798 - 2.45 = \mathbf{896.2 \text{ kJ/kg}}$$

$$\eta_{cycle} = w_{net} / q_H = 896.2 / 2507.3 = \mathbf{0.357}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Closed Feedwater Heaters

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.50

Write the analysis (continuity and energy equations) for the closed feed water heater with a drip pump as shown in Fig.9.13. Take the control volume to have state 4 out so it includes the drip pump. Find the equation for the extraction fraction.

CV Feedwater heater plus drip pump.

Continuity Eq.: $\dot{m}_6 + \dot{m}_2 = \dot{m}_4$

Energy Eq.: $\dot{m}_6 h_6 + \dot{m}_2 h_2 + \dot{m}_6 w_{P\ drip} = \dot{m}_4 h_4$

CV drip pump

$$w_{P\ drip} = v_6 (P_4 - P_6) = h_{6b} - h_{6a} \ ; \quad h_{6a} = h_{f\ at\ P6}$$

Divide the energy equation with the full flow rate ($\dot{m}_4$) to get

Energy Eq.: $y\ h_6 + (1 - y)\ h_2 + y\ w_{P\ drip} = h_4$

Now solve for the fraction $y = \dot{m}_6 / \dot{m}_4$

$$y = \frac{h_4 - h_2}{h_6 - h_2 + w_{P\ drip}}$$

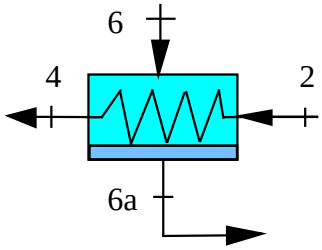
So to use this expression we assume we know states 2, 4 and 6 and have analyzed the drip pump. Of course if you assume state 3 is at the temperature of the condensing steam at state 6a then take CV to exclude the drip pump and the expression for y is different.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.51

A closed FWH in a regenerative steam power cycle heats 20 kg/s of water from 100°C, 20 MPa to 200°C, 20 MPa. The extraction steam from the turbine enters the heater at 4 MPa, 275°C, and leaves as saturated liquid. What is the required mass flow rate of the extraction steam?

Solution:
The schematic from Figure 9.13 has the feedwater from the pump coming at state 2 being heated by the extraction flow coming from the turbine state 6 so the feedwater leaves as saturated liquid state 4 and the extraction flow leaves as condensate state 6a.



From table B.1 h kJ/kg

B.1.4: 100°C, 20 MPa $h_2 = 434.04$

B.1.4: 200°C, 20 MPa $h_4 = 860.47$

B.1.3: 4 MPa, 275°C $h_6 = 2880.39$

B.1.2: 4 MPa, sat. liq. $h_{6a} = 1087.29$

C.V. Feedwater Heater

Energy Eq.: $\dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_2 h_4 + \dot{m}_6 h_{6a}$

Since all four states are known we can solve for the extraction flow rate

$$\dot{m}_6 = \dot{m}_2 \frac{h_2 - h_4}{h_{6a} - h_6}$$

$$= 20 \frac{434.04 - 860.47}{1087.29 - 2880.39} \text{ kg/s} = \mathbf{4.756\ kg/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

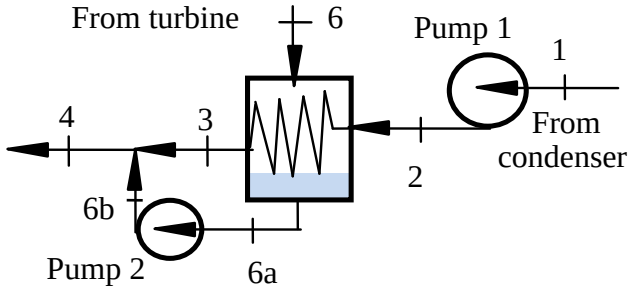
9.52

Find the specific turbine work from the extraction flow for the cycle in Problem 9.51 and the specific heat transfer in the boiler operating at 20 MPa, assuming the extraction flow goes through a drip pump and added to the feedwater line.

Solution:
The schematic from Figure 9.13 has the feedwater from the pump coming at state 2 (20 MPa, 100°C) being heated by the extraction flow coming from the turbine state 6 (4 MPa, 275°C) so the feedwater leaves at state 3 (20 MPa, 200°C) and the extraction flow leaves as condensate state 6a (4 MPa, x = 0) goes through the drip pump and added to the feedwater line to produce a state 4 (20 MPa, T = ?) going to the boiler.

From B.1 (h in kJ/kg):

$h_2 = 434.04$, $h_3 = 860.47$,
$h_6 = 2880.39$, $h_{6a} = 1087.29$
$v_{6a} = v_f = 0.001252\ m^3/kg$
$s_6 = s_5 = 6.2145$ kJ/kg-K



C.V. Feedwater Heater

Energy Eq.: $\dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_2 h_3 + \dot{m}_6 h_{6a}$

Since all four states are known we can solve for the extraction flow rate

$$\dot{m}_6 = \dot{m}_2 \frac{h_2 - h_3}{h_{6a} - h_6} = 20 \frac{434.04 - 860.47}{1087.29 - 2880.39}\ \text{kg/s} = 4.756\ \text{kg/s}$$

CV drip pump: $w_{P2} = v_{6a}(P_{6b} - P_{6a}) = 0.001252\ (20\,000 - 4000) = 20.03$ kJ/kg
$h_{6b} = h_{6a} + w_{P2} = 1087.29 + 20.03 = 1107.32$ kJ/kg

CV Junction 6b, 3, 4

$$h_4 = \frac{\dot{m}_2 h_3 + \dot{m}_6 h_{6b}}{\dot{m}_2 + \dot{m}_6} = \frac{20 \times 860.47 + 4.756 \times 1107.32}{20 + 4.756} = 907.89\ \text{kJ/kg}$$

We must assume state 5 is 20 MPa, $s = s_6$ so $h_5 = 3297.59$ kJ/kg, then

$w_{T\ ext\ flow} = h_5 - h_6 = 3297.59 - 2880.39 =$ **417.2 kJ/kg**
$q_{H\ ext\ flow} = h_5 - h_4 = 3297.59 - 907.89 =$ **2389.7 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.53

Assume the cycle in problem 9.51 has a condenser operating at 20 kPa, what would the quality at the turbine exit be? Find the reheat temperature if reheat is at the 4 MPa extraction pressure and the turbine should have a minimum quality of 90%.

Assume rev. adiabatic turbine so 4 MPa, 275°C: $s_5 = s_6 = s_7 = 6.2145$ kJ/kg-K

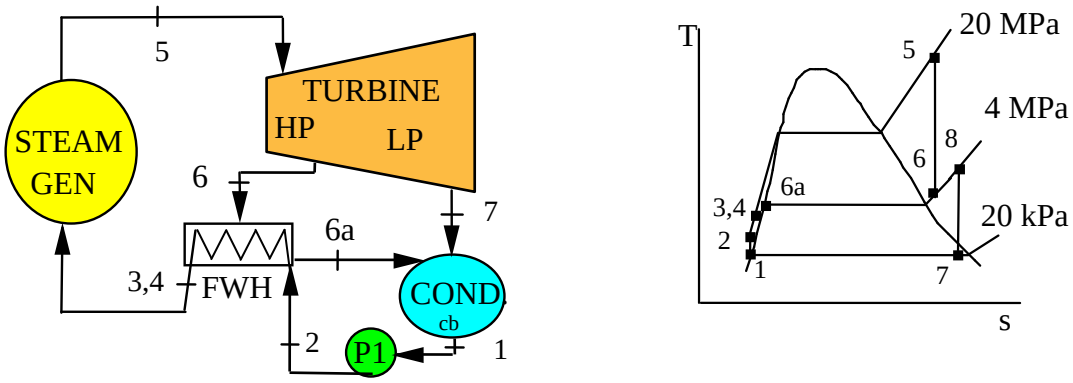
$$\Rightarrow \quad x_7 = \frac{6.2145 - 0.8319}{7.0766} = \mathbf{0.7606}$$

If we should have the new state 7 as $x_7 = 0.9$ then the entropy is:

$$s_7 = 0.8319 + 0.9 \times 7.0766 = 7.20084 \text{ kJ/kg-K}$$

this is then also entropy after reheat at 4 MPa, $s_8 = s_7$ so then

$$T_8 = 500 + 100 \frac{7.20084 - 7.09}{7.3688 - 7.09} = \mathbf{539.8°C}$$



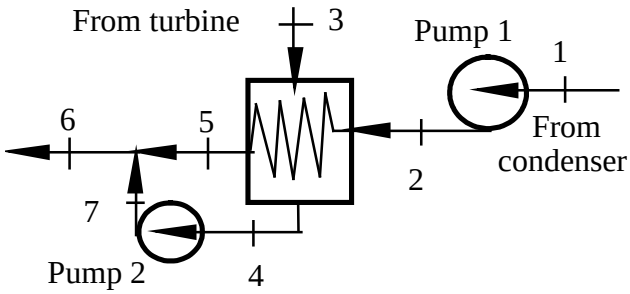
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.54

A power plant with one closed FWH has a condenser temperature of 45°C, a maximum pressure of 5 MPa, and boiler exit temperature of 900°C. Extraction steam at 1 MPa to the feedwater heater condenses and is pumped up to the 5 MPa feedwater line where all the water goes to the boiler at 200°C. Find the fraction of extraction steam flow and the two specific pump work inputs.

Solution:

s_1 = 0.6387 kJ/kg K,
h_1 = 188.42 kJ/kg
v_1 = 0.00101 m^3/kg,
s_4 = 2.1386 kJ/kg K,
h_4 = 762.79 kJ/kg
v_4 = 0.001127 m^3/kg
T_6 => h_6 = 853.85 kJ/kg



C.V. Turbine: Reversible, adiabatic so constant s from inlet to extraction point

$$s_3 = s_{IN} = 7.9593 \text{ kJ/kg K} \quad => \quad T_3 = \mathbf{573.8}, \quad h_3 = 3640.6 \text{ kJ/kg}$$

C.V. P1: $w_{P1} = v_1(P_2 - P_1) = 0.00101 \text{ m}^3\text{/kg} \times (5000 - 9.6) \text{ kPa} = \mathbf{5.04 \text{ kJ/kg}}$

$$\Rightarrow \quad h_2 = h_1 + w_{P1} = 188.42 + 5.04 = 193.46 \text{ kJ/kg}$$

C.V. P2: $w_{P2} = v_4(P_7 - P_4) = 0.001127 \text{ m}^3\text{/kg} \times (5 - 1) \text{ MPa} = \mathbf{4.508 \text{ kJ/kg}}$

$$\Rightarrow \quad h_7 = h_4 + w_{P2} = 762.79 + 4.51 = 767.30 \text{ kJ/kg}$$

C.V. FWH and pump 2:

The extraction fraction is: $y = \dot{\mathbf{m}}_3/\dot{\mathbf{m}}_6$

Continuity Eq.: $\dot{m}_6 = \dot{m}_2 + \dot{m}_3$, $1 = (1- y) + y$

Energy: $(1 - y)h_2 + y\, h_3 + y\, w_{P2} = h_6$

$$y = \frac{h_6 - h_2}{h_3 + w_{P2} - h_2} = \frac{853.85 - 193.46}{3640.6 + 4.508 - 193.46} = 0.1913$$

$$\dot{\mathbf{m}}_3/\dot{\mathbf{m}}_6 = \mathbf{y = 0.1913}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.55

Do Problem 9.43 with a closed feedwater heater instead of an open and a drip pump to add the extraction flow to the feed water line at 20 MPa. Assume the temperature is 175°C after the drip pump flow is added to the line. One main pump brings the water to 20 MPa from the condenser.

Solution:

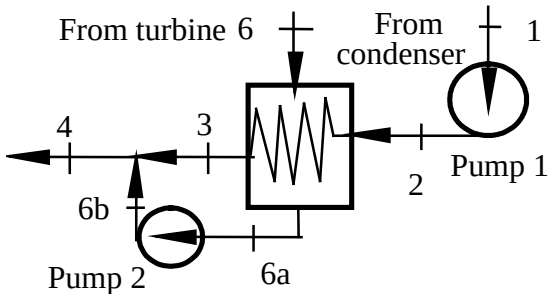
$v_1 = 0.00101\ m^3/kg$,

$h_1 = 191.81\ kJ/kg$

$T_4 = 175^oC$; $h_4 = 751.66\ kJ/kg$

$h_{6a} = h_{f\ 1MPa} = 762.79\ kJ/kg$,

$v_{6a} = 0.001127\ m^3/kg$



Turbine section 1: $s_6 = s_5 = 7.0544\ kJ/kg\ K$

$P_6 = 1\ MPa \quad => \quad h_6 = 3013.7\ kJ/kg$

C.V Pump 1

$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.00101(20\ 000 - 10) = 20.19\ kJ/kg$

$=> \quad h_2 = h_1 + w_{P1} = 191.81 + 20.19 = 212.0\ kJ/kg$

C.V Pump 2

$w_{P2} = h_{6b} - h_{6a} = v_{6a}(P_{6b} - P_{6a}) = 0.001127(20\ 000 - 1000) = 21.41\ kJ/kg$

C.V FWH + P2 select the extraction fraction to be $y = \dot{m}_6 / \dot{m}_4$

$y\ h_6 + (1 - y)\ h_2 + y\ (w_{P2}) = h_4$

$$y = \frac{h_4 - h_2}{h_6 - h_2 + w_{P2}} = \frac{751.66 - 212.0}{3013.7 - 212.0 + 21.41} = \mathbf{0.191}$$

Turbine: $s_7 = s_6 = s_5$ & $P_7 = 10\ kPa$

$$=> \quad x_7 = \frac{7.0544 - 0.6493}{7.5009} = 0.85391$$

$h_7 = 191.81 + 0.85391 \times 2392.82 = 2235.1\ kJ/kg$

$w_T = [\ h_5 - h_6 + (1 - y)\ (h_6 - h_7)\ ]$

$= [\ 4069.8 - 3013.7 + 0.809\ (3013.7 - 2235.1)] = 1686\ kJ/kg$

$\dot{W}_T = 5000\ kW = \dot{m}_5 \times w_T = \dot{m}_5 \times 1686\ kJ/kg \quad => \quad \dot{m}_5 = 2.966\ kg/s$

$\dot{Q}_L = \dot{m}_5(1 - y)\ (h_7 - h_1) = 2.966 \times 0.809\ (2235.1 - 191.81) = \mathbf{4903\ kW}$

9.56

Repeat Problem 9.49, but assume a closed instead of an open feedwater heater. A single pump is used to pump the water leaving the condenser up to the boiler pressure of 3.0 MPa. Condensate from the feedwater heater is going through a drip pump and added to the feedwater line so state 4 is at T_6.

Solution:

C.V. Turbine, 2nd law:

$s_5 = s_6 = s_7 = 6.9211$ kJ/kg K

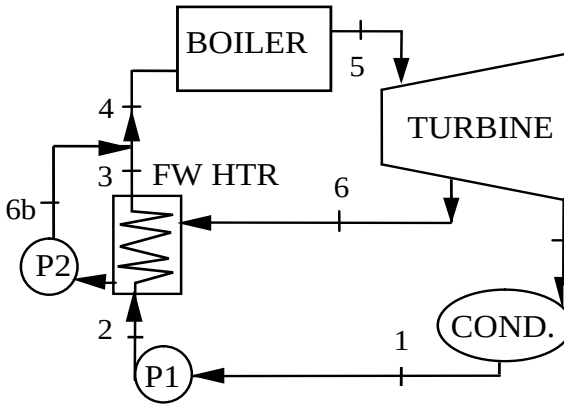
$h_5 = 3230.82$, $h_6 = 2891.6$

$\Rightarrow x_7 = (6.9211 - 0.6492)/7.501$

$= 0.83614$

$h_7 = 191.81 + x_7\ 2392.82$

$= 2192.55$ kJ/kg



Assume feedwater heater exit state 4 at the T of the condensing steam

C.V Pump 1

$$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.00101(3000 - 10) = 3.02 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{P1} = 191.81 + 3.02 = 194.83 \text{ kJ/kg}$$

$$T_4 = T_{sat}(P_6) = 170.43°C, \quad h_4 \approx h_f = h_{6a} = 721.1 \text{ kJ/kg}$$

C.V Pump 2 (the drip pump)

$$w_{P2} = h_{6b} - h_{6a} = v_{6a}(P_{6b} - P_{6a}) = 0.001115(3000 - 800) = 2.45 \text{ kJ/kg}$$

C.V FWH + P2 select the extraction fraction to be $y = \dot{m}_6 / \dot{m}_4$

$$y\,h_6 + (1 - y)\,h_2 + y\,(w_{P2}) = h_4$$

$$y = \frac{h_4 - h_2}{h_6 - h_2 + w_{P2}} = \frac{721.1 - 194.83}{2891.6 - 194.83 + 2.45} = \mathbf{0.195}$$

Turbine work with full flow from 5 to 6 fraction 1– y flows from 6 to 7

$$w_T = [\, h_5 - h_6 + (1 - y)\,(h_6 - h_7)\,]$$

$$= [\, 3230.82 - 2891.6 + 0.805\,(2891.6 - 2192.55)] = 901.95 \text{ kJ/kg}$$

$$w_{net} = w_T - (1-y)w_{P1} - x w_{P2} = 901.95 - 0.805 \times 3.02 - 0.195 \times 2.45$$

$$= \mathbf{899.0 \text{ kJ/kg}}$$

$$q_H = h_5 - h_4 = 3230.82 - 721.1 = 2509.7 \text{ kJ/kg}$$

$$\eta_{cycle} = w_{net} / q_H = 899.0 / 2509.7 = \mathbf{0.358}$$

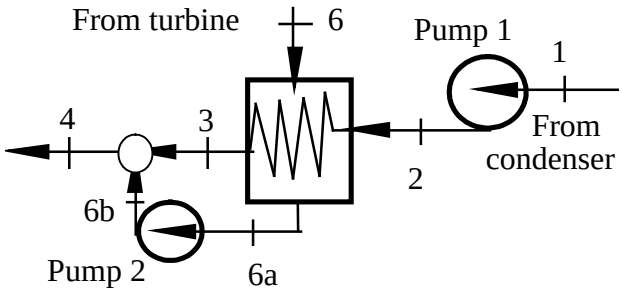
9.58

A Rankine cycle feeds 5 kg/s ammonia at 2 MPa, 140°C to the turbine, which has an extraction point at 800 kPa. The condenser is at -20°C and a closed feed water heater has an exit state (3) at the temperature of the condensing extraction flow and it has a drip pump. The source for the boiler is at constant 180°C. Find the extraction flow rate and state 4 into the boiler.

P_1 = 190.2 kPa,
h_1 = 89.05 kJ/kg
v_1 = 0.001504 m^3/kg,
s_5 = 5.5022 kJ/kg K,
h_5 = 1738.2 kJ/kg
$T_{6a} = T_{sat\ 800\ kPa}$ = 17.85°C
=> h_{6a} = 264.18 kJ/kg



C.V. Turbine: Reversible, adiabatic so constant s from inlet to extraction point

$$s_6 = s_{IN} = 5.5022 \text{ kJ/kg K} \quad \Rightarrow \quad T_6 = 63.4^{o}\text{C}, \quad h_6 = 1580.89 \text{ kJ/kg}$$

C.V. P1: $w_{P1} = v_1(P_2 - P_1) = 0.001504(2000 - 190.2) = 2.722$ kJ/kg

$$\Rightarrow \quad h_2 = h_1 + w_{P1} = 91.772 \text{ kJ/kg}$$

C.V. P2: $w_{P2} = v_{6a}\,(P_4 - P_6) = 0.0016108\ (2000 - 800) = 1.933$ kJ/kg

$$\Rightarrow \quad h_{6b} = h_{6a} + w_{P2} = 266.11 \text{ kJ/kg}$$

C.V. Total FWH and pump (notice $h_3 = h_{6a}$ as we do not have table for this state)

The extraction fraction is: $y = \dot{m}_6/\dot{m}_4$

Energy: $(1 - y)h_2 + yh_6 = (1 - y)h_3 + yh_{6a}$

$$y = \frac{h_3 - h_2}{h_3 - h_2 + h_6 - h_{6a}} = \frac{264.18 - 91.772}{264.18 - 91.772 + 1580.89 - 264.18} = 0.1158$$

$$\dot{m}_6 = y\,\dot{m}_4 = 0.1158 \times 5 = \mathbf{0.5789\ kg/s}$$

C.V. The junction after FWH and pump 2.

$$h_4 = (1-y)h_3 + y\,h_{6b} = (1- 0.1158) \times 264.18 + 0.1158 \times 266.11 = 264.4 \text{ kJ/kg}$$

Interpolate in Table B.2.1: $T_4 = \mathbf{17.92^{o}C}$

9.59

Assume the powerplant in Problem 9.45 has one closed feedwater heater instead of the open FWH. The extraction flow out of the FWH is saturated liquid at 2033 kPa being dumped into the condenser and the feedwater is heated to 50°C. Find the extraction flow rate and the total turbine power output.

State 1: $x_1 = 0$, $h_1 = 298.25$ kJ/kg, $v_1 = 0.001658$ m^3/kg

State 3: $h_3 = h_f + (P_3 - P_{sat})v_f = 421.48 + (5000 - 2033)0.001777 = 426.75$ kJ/kg

State 5: $h_5 = 421.48$ kJ/kg, $s_5 = 4.7306$ kJ/kg K

State 6: $s_6 = s_5 \Rightarrow x_6 = (s_6 - s_f)/s_{fg} = 0.99052$, $h_6 = 1461.53$ kJ/kg

State 6a: $x_{6a} = 0 \Rightarrow h_{6a} = 421.48$ kJ/kg

State 7: $s_7 = s_5 \Rightarrow x_7 = (s_7 - s_f)/s_{fg} = 0.9236$, $h_7 = 1374.43$ kJ/kg

C.V Pump P1

$$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.001658(5000 - 1003) = 6.627 \text{ kJ/kg}$$

$$\Rightarrow h_2 = h_1 + w_{P1} = 298.25 + 6.627 = 304.88 \text{ kJ/kg}$$

C.V. Feedwater heater: Call $\dot{m}_6 / \dot{m}_{tot} = y$ (the extraction fraction)

Energy Eq.: $h_2 + y\, h_6 = 1\, h_3 + y\, h_{6a}$

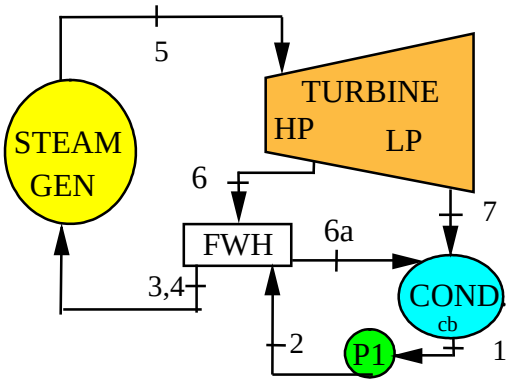
$$y = \frac{h_3 - h_2}{h_6 - h_{6a}} = \frac{426.75 - 304.88}{1461.53 - 421.48} = \mathbf{0.1172}$$

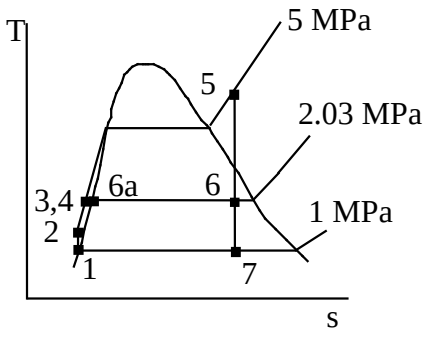
$$\dot{m}_{extr} = y\, \dot{m}_{tot} = 0.1172 \times 5 = \mathbf{0.586\ kg/s}$$

Total turbine work

$$\dot{W}_T = \dot{m}_{tot}(h_5 - h_6) + (1 - y)\dot{m}_{tot}(h_6 - h_7)$$

$$= 5(1586.3 - 1461.53) + (5 - 0.586)(1461.53 - 1374.43) = \mathbf{1008\ kW}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.60

Assume a variation of the cycle in Problem 9.49 with a closed FWH at 0.8 MPa and one open FWH at 100 kPa. A pump is used to bring the water leaving the condenser up to 100 kPa for an open FWH and a second pump brings the feedwater up to 3.0 MPa as shown in Fig. P9.60. Condensate from the closed FWH is drained through a trap to the open FWH. Calculate the thermal efficiency of the cycle and the specific net work.

Solution:

This is a Rankine cycle with an open FWH and a closed FWH shown in Fig. P9.60.

Here state 6 is out of boiler, state 8 is extraction at 100 kPa, state 9 is out of turbine.

States 1: 10 kPa, x = 0: $h_1 = 191.81$ kJ/kg, $v_1 = 0.001010$ m^3/kg

3: 100 kPa, x = 0: $h_3 = 417.44$ kJ/kg, $v_3 = 0.001043$ m^3/kg

5: 3 MPa, T = $T_{7a} = 170.43^oC$: $h_5 \approx 721.1$ kJ/kg (= h_{7a})

6: 3 MPa, 400^{o}C: $h_6 = 3230.82$ kJ/kg, $s_6 = 6.9211$ kJ/kg-K

7: 800 kPa, s = s_6: $h_7 = 2891.62$ kJ/kg (sup. vapor)

7a: 800 kPa, x = 0: $h_{7a} = h_f = 721.1$ kJ/kg

8: 100 kPa, s = s_6: $x_8 = (6.9211 - 1.3025)/6.0568 = 0.92765$

$h_8 = 417.44 + x_8\ 2258.02 = 2512.09$ kJ/kg

9: 10 kPa, s = s_6: $x_9 = (6.9211 - 0.6492)/7.501 = 0.83614$

$h_9 = 191.81 + x_9\ 2392.82 = 2192.55$ kJ/kg

C.V Pump P1

$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.00101(100 - 10) = 0.0909$ kJ/kg

=> $h_2 = h_1 + w_{P1} = 191.81 + 0.0909 = 191.9$ kJ/kg

C.V Pump P2

$w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.001043(3000 - 100) = 3.025$ kJ/kg

$h_4 = h_3 + w_{P2} = 417.44 + 3.025 = 420.465$ kJ/kg

Since the open FWH has a flow in from the trap we must do that first.

C.V. Closed FWH Call $\dot{m}_7 / \dot{m}_{tot} = y_1$ (the extraction fraction)

Energy Eq.: $0 = h_4 - h_5 + y_1(h_7 - h_{7a})$ => $y_1 = \dfrac{h_5 - h_4}{h_7 - h_{7a}} = \dfrac{721.1 - 420.465}{2891.62 - 721.1} = 0.1385$

9.61

A steam power cycle has a high pressure of 3.0 MPa and a condenser exit temperature of 45°C. The turbine efficiency is 85%, and other cycle components are ideal. If the boiler superheats to 800°C, find the cycle thermal efficiency.

Solution:

Basic Rankine cycle as shown in Figure 9.3 in the main text.

C.V. Turbine: $w_T = h_3 - h_4$, $s_4 = s_3 + s_{T,GEN}$

Ideal: Table B.1.3: $s_4 = s_3 = 7.9862$ kJ/kg K

$\Rightarrow x_{4s} = (7.9862 - 0.6386)/7.5261 = 0.9763$

$h_{4s} = h_f + x\, h_{fg} = 188.42 + 0.9763 \times 2394.77 = 2526.4$ kJ/kg

$w_{Ts} = h_3 - h_{4s} = 4146 - 2526.4 = 1619.6$ kJ/kg

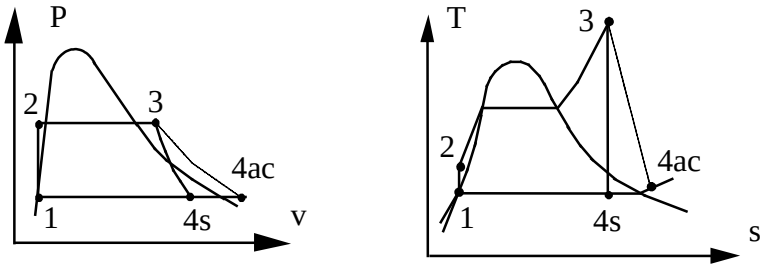
Actual: $w_{T,AC} = \eta \times w_{T,S} = 0.85 \times 1619.6 = 1376.66$ kJ/kg

C.V. Pump: $w_P = \int v\, dP \approx v_1(P_2 - P_1) = 0.00101\ (3000 - 9.6) = 3.02$ kJ/kg

$h_2 = h_1 + w_P = 188.42 + 3.02 = 191.44$ kJ/kg

C.V. Boiler: $q_H = h_3 - h_2 = 4146 - 191.44 = 3954.6$ kJ/kg

$\eta = (w_{T,AC} - w_P)/q_H = (1376.66 - 3.02)/3954.6 =$ **0.347**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.62

A Rankine cycle with water superheats to 500°C at 3 MPa in the boiler and the condenser operates at 100°C. All components are ideal except the turbine which has an exit state measured to be saturated vapor at 100°C. Find the cycle efficiency with a) an ideal turbine and b) the actual turbine.

Standard Rankine cycle 1-2-3-4s for ideal turbine.
Modified Rankine cycle 1-2-3-4ac for actual turbine

Table B.1.1: $v_1 = 0.001044\ m^3/kg$, $h_1 = 419.02$ kJ/kg
$h_3 = 3456.48$ kJ/kg, $s_3 = 7.2337$ kJ/kg-K

State 4s: $s_{4s} = s_3 = 7.2337 = s_f + x_{4s}\, s_{fg} = 1.3068 + x_{4s}\, 6.0480 \Rightarrow x_{4s} = 0.97998$
$\Rightarrow h_{4s} = h_f + x_{4s} h_{fg} = 419.02 + x_{4s}\, 2257.03 = 2630.9$ kJ/kg

State 4ac: $h_{4ac} = h_g = 2676.05$ kJ/kg

C.V. Pump: Assume adiabatic, reversible and incompressible flow

$$w_{ps} = \int v\, dP = v_1(P_2 - P_1) = 3.03 \text{ kJ/kg}$$

$$h_2 = h_1 + w_p = 419.02 + 3.03 = 422.05 \text{ kJ/kg}$$

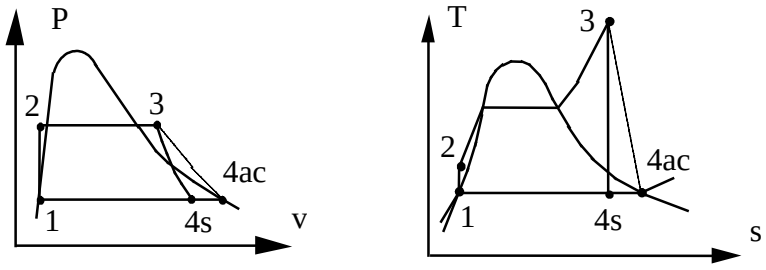
C.V. Boiler $q_B = h_3 - h_2 = 3456.48 - 422.05 = 3034.4$ kJ/kg

C.V. Turbine; $w_{Ts} = h_3 - h_{4s} = 3456.48 - 2630.9 = 825.58$ kJ/kg

Efficiency: $\eta_{th} = w_{net} / q_B = (825.58 - 3.03)/3034.4 =$ **0.271**

Actual turbine: $w_{Tac} = h_3 - h_{4ac} = 3456.48 - 2676.05 = 780.43$ kJ/kg

Efficiency: $\eta_{th} = w_{net} / q_B = (780.43 - 3.03)/3034.4 =$ **0.256**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.63

For the steam power plant described in Problem 9.13, assume the isentropic efficiencies of the turbine and pump are 85% and 80%, respectively. Find the component specific work and heat transfers and the cycle efficiency.

Solution:

This is a standard Rankine cycle with actual non-ideal turbine and pump.

CV Pump, Rev & Adiabatic:

$$w_{Ps} = h_{2s} - h_1 = v_1(P_2 - P_1) = 0.00101(3000 - 10) = 3.02 \text{ kJ/kg}; \quad s_{2s} = s_1$$

$$w_{Pac} = w_{Ps} / \eta_P = 3.02/0.8 = \mathbf{3.775} \text{ kJ/kg} = h_{2a} - h_1$$

$$h_{2a} = w_{Pac} + h_1 = 3.775 + 191.81 = 195.58 \text{ kJ/kg}$$

CV Boiler: $q_H = h_3 - h_{2a} = 2804.14 - 195.58 = \mathbf{2608.56 \text{ kJ/kg}}$

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$

$$s_4 = s_3 = 6.1869 = 0.6492 + x_4 (7.501) \quad \Rightarrow \quad x_4 = 0.7383$$

$$\Rightarrow \; h_4 = 191.81 + 0.7383 (2392.82) = 1958.34 \text{ kJ/kg}$$

$$w_{Ts} = 2804.14 - 1958.34 = 845.8 \text{ kJ/kg}$$

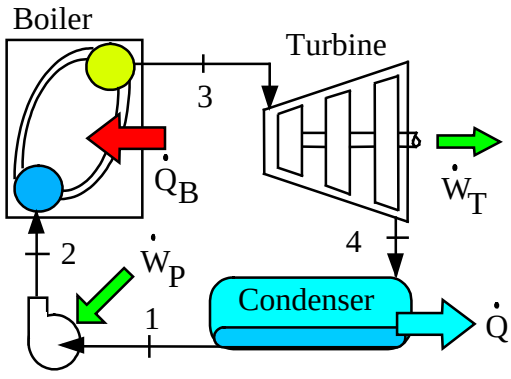
$$w_{Tac} = w_{Ts} \times \eta_T = \mathbf{718.9} = h_3 - h_{4a}$$

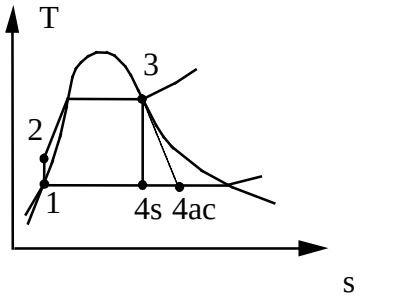
$$h_{4a} = h_3 - w_{Tac} = 2804.14 - 718.9 = 2085.24 \text{ kJ/kg}$$

CV Condenser: $q_L = h_{4a} - h_1 = 2085.24 - 191.81 = \mathbf{1893.4 \text{ kJ/kg}}$

$$\eta_{cycle} = \frac{w_{Tac} - w_{Pac}}{q_H} = \frac{718.9 - 3.78}{2608.56} = \mathbf{0.274}$$

This compares to 0.32 for the ideal case.





state 2s and 2ac nearly the same

9.64

Steam enters the turbine of a power plant at 5 MPa and 400°C, and exhausts to the condenser at 10 kPa. The turbine produces a power output of 20 000 kW with an isentropic efficiency of 85%. What is the mass flow rate of steam around the cycle and the rate of heat rejection in the condenser? Find the thermal efficiency of the power plant and how does this compare with a Carnot cycle.

Solution: $\dot{W}_T = 20\ 000$ kW and $\eta_{Ts} = 85\ \%$

State 3: $h_3 = 3195.6$ kJ/kg , $s_3 = 6.6458$ kJ/kgK

State 1: $P_1 = P_4 = 10$ kPa , sat liq , $x_1 = 0$

$T_1 = 45.8^oC$, $h_1 = h_f = 191.8$ kJ/kg , $v_1 = v_f = 0.00101\ m^3/kg$

C.V Turbine energy Eq.: $q_T + h_3 = h_4 + w_T$; $q_T = 0$

$w_T = h_3 - h_4$, Assume Turbine is isentropic

$s_{4s} = s_3 = 6.6458$ kJ/kgK , $s_{4s} = s_f + x_{4s}\, s_{fg}$, solve for $x_{4s} = 0.7994$

$h_{4s} = h_f + x_{4s}h_{fg} = 191.81 + x_{4s}\ 2392.82 = 2104.6$ kJ/kg

$w_{Ts} = h_3 - h_{4s} = 1091$ kJ/kg , $w_T = \eta_{Ts} w_{Ts} = 927.3$ kJ/kg

$$\dot{m} = \frac{\dot{W}_T}{w_T} = \mathbf{21.568\ kg/s}\ , \quad h_4 = h_3 - w_T = 2268.3\ \text{kJ/kg}$$

C.V. Condenser: energy Eq.: $h_4 = h_1 + q_c + w_c$; $w_c = 0$

$q_c = h_4 - h_1 = 2076.5$ kJ/kg , $\dot{Q}_c = \dot{m}\, q_c = \mathbf{44\ 786\ kW}$

C.V. Pump: Assume adiabatic, reversible and incompressible flow

$w_{ps} = \int v\, dP = v_1(P_2 - P_1) = 5.04$ kJ/kg

energy Eq.: $h_2 = h_1 + w_p = 196.8$ kJ/kg

C.V Boiler : energy Eq.: $q_B + h_2 = h_3 + w_B$; $w_B = 0$

$q_B = h_3 - h_2 = 2998.8$ kJ/kg

$w_{net} = w_T - w_P = 922.3$ kJ/kg

$\eta_{th} = w_{net} / q_B = \mathbf{0.307}$

Carnot cycle : $T_H = T_3 = 400^oC$, $T_L = T_1 = 45.8^oC$

$$\eta_{th} = \frac{T_H - T_L}{T_H} = \mathbf{0.526}$$

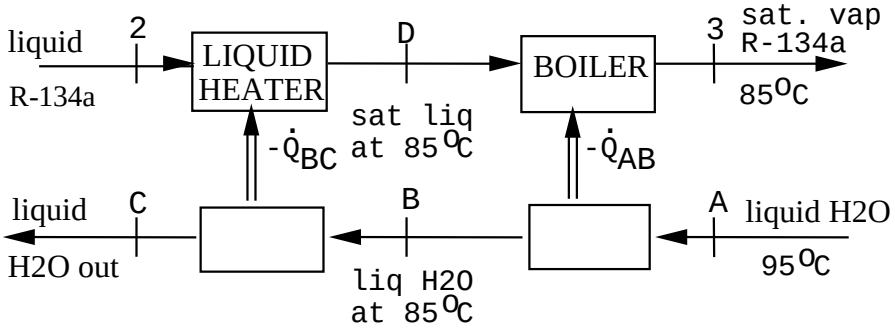
9.65

Consider the boiler in Problem 9.21 where the geothermal hot water brings the R-134a to saturated vapor. Assume a counter flowing heat exchanger arrangement. The geothermal water temperature should be equal to or greater than the R-134a temperature at any location inside the heat exchanger. The point with the smallest temperature difference between the source and the working fluid is called the pinch point. If 2 kg/s of geothermal water is available at 95°C, what is the maximum power output of this cycle for R-134a as the working fluid? (hint: split the heat exchanger C.V. into two so the pinch point with $\Delta T = 0$, T = 85°C appears).

2 kg/s of water is available at 95 °C for the boiler. The restrictive factor is the boiling temperature of 85° C. Therefore, break the process up from 2-3 into two parts as shown in the diagram.



CV Pump: $w_P = v_1(P_2-P_1) = 0.000873(2926.2 - 1017.0) = 1.67$ kJ/kg

$h_2 = h_1 + w_P = 256.54 + 1.67 = 258.21$ kJ/kg

Write the energy equation for the first section A-B and D-3:

$$-\dot{Q}_{AB} = \dot{m}_{H2O}(h_A - h_B) = 2(397.94 - 355.88) = 84.12 \text{ kW}$$

$$= \dot{m}_{R134A}(428.1 - 332.65) \Rightarrow \dot{m}_{R134A} = 0.8813 \text{ kg/s}$$

To be sure that the boiling temp. is the restrictive factor, calculate T_C from the energy equation for the remaining section:

$$-\dot{Q}_{AC} = 0.8813(332.65 - 258.21) = 65.60 \text{ kW} = 2(355.88 - h_C)$$

$\Rightarrow$ $h_C = 323.1$ kJ/kg, $T_C = 77.2°C > T_2 = 40°C$ **OK**

CV: Turbine: $s_4 = s_3 = 1.6782 = 1.1909 + x_4 \times 0.5214$ => $x_4 = 0.9346$

$h_4 = 256.54 + 0.9346 \times 163.28 = 409.14$ kJ/kg

Energy Eq.: $w_T = h_3 - h_4 = 428.1 - 409.14 = 18.96$ kJ/kg

Cycle: $w_{NET} = w_T - w_P = 18.96 - 1.67 = 17.29$ kJ/kg

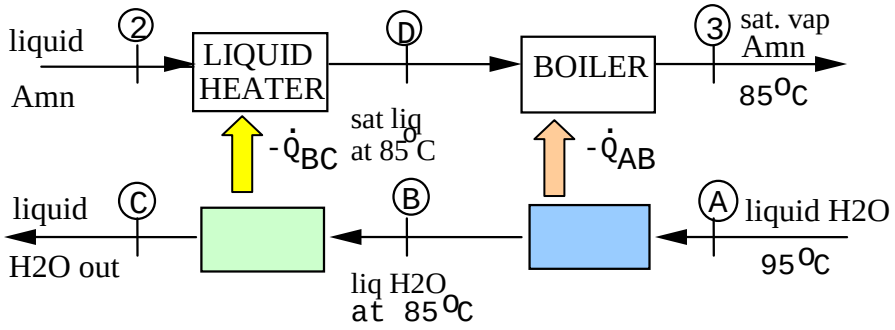
$$\dot{W}_{NET} = \dot{m}_{R134A} w_{NET} = 0.8813 \times 17.29 = \mathbf{15.24\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.66

Do the previous problem with ammonia as the working fluid.

A flow with 2 kg/s of water is available at 95°C for the boiler. The restrictive factor is the boiling temperature of 85°C. Therefore, break the process up from 2-3 into two parts as shown in the diagram.



State 1: 40^oC, 1554.9 kPa, $v_1 = 0.001725\ m^3/kg$

CV Pump: $w_P = v_1(P_2 - P_1) = 0.001725(4608.6 - 1554.9) = 5.27\ kJ/kg$

$h_2 = h_1 + w_P = 371.43 + 5.27 = 376.7\ kJ/kg$

$-\dot{Q}_{AB} = \dot{m}_{H2O}(h_A - h_B) = 2(397.94 - 355.88) = 84.12\ kW$

$= \dot{m}_{amn}(1447.8 - 609.21) \Rightarrow \dot{m}_{amn} = 0.100\ kg/s$

To verify that $T_D = T_3$ is the restrictive factor, find T_C.

$-\dot{Q}_{AC} = 0.100(609.21 - 376.7) = 23.25 = 2.0(355.88 - h_C)$

$h_C = 344.25\ kJ/kg \Rightarrow T_C = 82.5^oC > T_2 = 40^oC$ **OK**

CV: Turbine

$s_4 = s_3 = 4.3901 = 1.3574 + x_4 \times 3.5088 \quad \Rightarrow \quad x_4 = 0.8643$

$h_4 = 371.43 + 0.8643 \times 1098.8 = 1321.13\ kJ/kg$

Energy Eq.:

$w_T = h_3 - h_4 = 1447.8 - 1321.13 = 126.67\ kJ/kg$

$w_{NET} = w_T - w_P = 126.67 - 5.27 = 121.4\ kJ/kg$

$\dot{W}_{NET} = \dot{m}_{amn} w_{NET} = 0.1 \times 121.4 =$ **12.14 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.67

A **concentrated solar power** plant receives the energy from molten salt coming in at 560°C and leaving at 300°C in a counterflow heat exchanger where the water comes in at 3 MPa, 60°C and leaves at 450°C, 3 MPa. The molten salt has 5 kg/s flow with Cp = 1.5 kJ/kgK. What is the possible water flow rate, the rate of energy transfer and rate of entropy generation.

Continuity Eqs.: Each line has a constant flow rate through it.

Energy Eq.4.10: $0 = \dot{m}_{H_2O} (h_1 - h_2) + \dot{m}_{salt} (h_3 - h_4)$

Entropy Eq.7.7: $0 = \dot{m}_{H_2O} (s_1 - s_2) + \dot{m}_{salt} (s_3 - s_4) + \dot{S}_{gen}$

Process: Each line has a constant pressure.

Table B.1: $h_1 = 253.61$ kJ/kg, $h_2 = 3344$ kJ/kg, $s_1 = 0.8295$, $s_2 = 7.0833$ kJ/kg-K

From the energy leaving the salt we get

$$\dot{Q} = \dot{m}_{salt} (h_3 - h_4) = \dot{m}_{salt} C_{P\,salt} (T_3 - T_4)$$

$$= 5 \times 1.5 [560 - 300] = \mathbf{1950\ kW}$$

$$\dot{m}_{H_2O} = \dot{m}_{salt} \frac{h_3 - h_4}{h_2 - h_1} = \frac{\dot{Q}}{h_2 - h_1} = \frac{1950\ \text{kW}}{(3344 - 253.61)\ \text{kJ/kg}} = \mathbf{0.631\ kg/s}$$

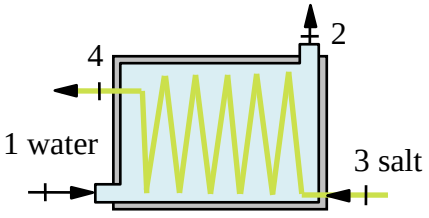
$$s_4 - s_3 = C_{P\,salt} \ln (T_4/T_3) = 1.5 \ln(573.15/833.15) = -0.561\ \text{kJ/kgK}$$

$$\dot{S}_{gen} = \dot{m}_{H_2O} (s_2 - s_1) + \dot{m}_{salt} (s_4 - s_3)$$

$$= 0.631\ \text{kg/s}\ (7.0833 - 0.8295)\ \text{kJ/kgK} + 5\ \text{kg/s} \times (-0.561\ \text{kJ/kgK})$$

$$= \mathbf{1.14\ kW/K}$$

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for salt and water each. The two flows exchange energy with no heat transfer to/from the outside.



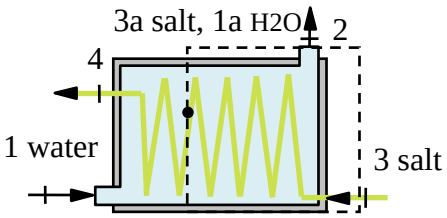
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.68

Look at the pinch point for the heat exchanger in Problem 9.67 the same way it is explained in Problem 9.65 and determine the maximum possible water flow rate for a pinch point $\Delta T = 10$ K.

C.V. Part of the heat exchanger from the salt inlet to state 3a for the salt and then from state 1a for the water to its outlet at state 2.

Pinch point: $T_{3a} = T_{1a} + 10 = 243.9^{o}C$



Energy Eq.: $0 = \dot{m}_{H_2O}\,(h_{1a} - h_2) + \dot{m}_{salt}\,(h_3 - h_{3a})$

$$\dot{Q} = \dot{m}_{salt}\,(h_3 - h_{3a}) = \dot{m}_{salt}\,C_{P\,salt}\,(T_3 - T_{3a})$$

$$= 5 \times 1.5 \times (560 - 243.9) = 2370.75 \text{ kW}$$

$$\dot{m}_{H_2O} = \frac{\dot{Q}}{h_2 - h_1} = \frac{2370.75 \text{ kW}}{(3344 - 1008.41) \text{ kJ/kg}} = \mathbf{1.015 \text{ kg/s}}$$

Check also for the salt outlet condition, take the missing CV

Energy Eq.: $\dot{m}_{H_2O}\,(h_{1a} - h_1) = \dot{m}_{salt}\,C_{P\,salt}\,(T_{3a} - T_4)$

$$1.015\,(1008.41 - 253.61) = 5 \times 1.5 \times (243.9 - T_4)$$

Solve for T_4 : $T_4 = 243.9 - 102 = 141.7^{o}C$

This temperature is too low, the salt would solidify so the pinch point ΔT should be much higher.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.69

A steam power plant operates with a high pressure of 4 MPa and has a boiler exit of 600°C receiving heat from a 750°C source. The ambient at 20°C provides cooling to maintain the condenser at 60°C, all components are ideal except for the turbine which has an isentropic efficiency of 92%. Find the ideal and the actual turbine exit qualities. Find the actual specific work and specific heat transfer in all four components.

Solution:

A standard Rankine cycle with an actual non-ideal turbine.

Boiler exit: $h_3 = 3674.44$ kJ/kg, $s_3 = 7.3688$ kJ/kg K

Condenser exit: $h_1 = 251.11$ kJ/kg,

Ideal Turbine: 4s: 50°C, $s = s_3 \Rightarrow x_{4s} = (7.3688 - 0.8311)/7.0784 =$ **0.9236**,

$h_{4s} = 251.11 + 0.9236 \times 2358.48 = 2429.43$ kJ/kg

$\Rightarrow \quad w_{Ts} = h_3 - h_{4s} = 1245.01$ kJ/kg

Actual turbine: $w_{Tac} = \eta_{T\,s} w_{Ts} = 0.92 \times 1245.01 =$ **1145.4 kJ/kg =** $h_3 - h_{4ac}$

$h_{4ac} = h_3 - w_{Tac} = 3674.44 - 1145.4 = 2529.04$ kJ/kg

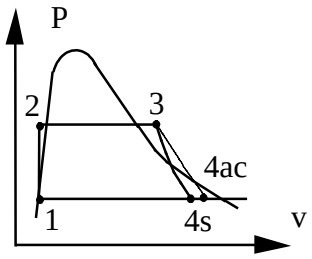
$x_{4ac} = (2529.04 - 251.11)/2358.48 =$ **0.96585**

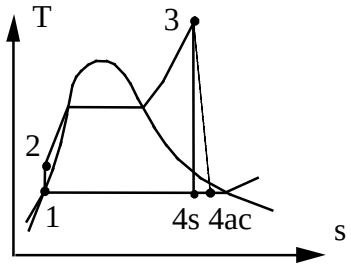
Pump: $w_P = v_1(P_2 - P_1) = 0.001017(4000 - 19.94) =$ **4.05 kJ/kg**

$h_2 = h_1 + w_P = 251.11 + 4.05 = 255.16$ kJ/kg

$q_H = h_3 - h_2 = 3674.44 - 255.16 =$ **3419.3 kJ/kg**

$q_L = h_{4ac} - h_1 = 2529.04 - 251.11 =$ **2277.9 kJ/kg**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.70

For the previous Problem find also the specific entropy generation in the boiler heat source setup.

CV. Boiler out to the source.

Entropy Eq.: $s_2 + \frac{q_H}{T_{source}} + s_{gen} = s_3$

State 1: Sat. liquid $h_1 = 251.11$ kJ/kg, $s_1 = 0.8311$ kJ/kgK

Pump: $w_P = v_1(P_2 - P_1) = 0.001017(4000 - 19.94) = 4.05$ kJ/kg

State 2: $h_2 = h_1 + w_P = 251.11 + 4.05 = 255.16$ kJ/kg, $s_2 = s_1$

State 3: $h_3 = 3674.44$ kJ/kg, $s_3 = 7.3688$ kJ/kgK

Boiler: $q_H = h_3 - h_2 = 3674.44 - 255.16 = 3419.3$ kJ/kg

$$s_{gen} = s_3 - s_2 - \frac{q_H}{T_{source}} = 7.3688 - 0.8311 - \frac{3419.3}{750 + 273} = \mathbf{3.195\ kJ/kgK}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.71

Consider the power plant in Problem 9.41. Assume the high temperature source is a flow of liquid water at 120°C into a heat exchanger at constant pressure 300 kPa and that the water leaves at 90°C. Assume the condenser rejects heat to the ambient which is at -20°C. List all the places that have entropy generation and find the entropy generated in the boiler heat exchanger per kg ammonia flowing.

Solution:

a) The hot water/ammonia boiler.

b) The condensing ammonia (-15°C) to the ambient (-20°C) heat transfer.

c) The "feedwater" heater has mixing of a flow at state 6 with a flow at state 2.

State 3: $x_3 = 0$, $h_3 = 171.65$ kJ/kg, $v_3 = 0.00156$ m^3/kg, $s_3 = 0.6793$ kJ/kgK

State 5: $h_5 = 1614.6$ kJ/kg, $s_5 = 5.4971$ kJ/kg K

C.V Pump P2 (rev. and adiabatic so $s_4 = s_3$).

$$w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.00156(1000 - 400) = 0.936 \text{ kJ/kg}$$

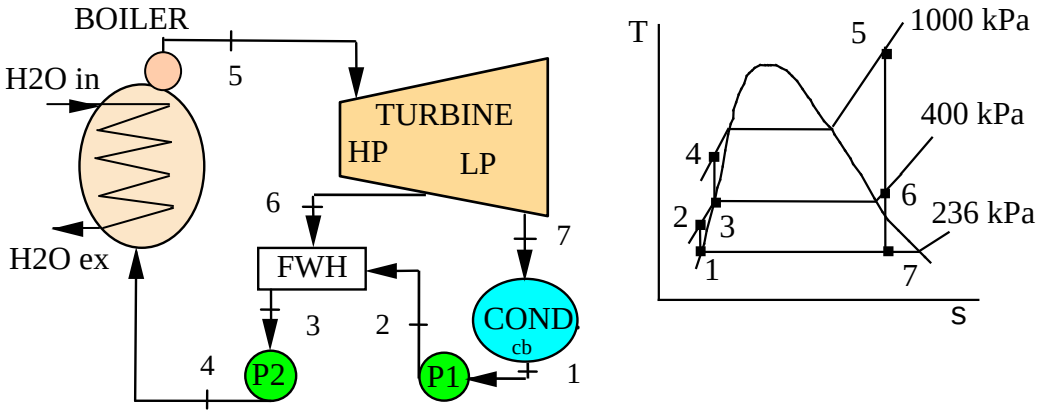
$$\Rightarrow h_5 - h_4 = h_5 - h_3 - w_{P2} = 1614.6 - 171.65 - 0.936 = 1442 \text{ kJ/kg}$$

C.V. Boiler: Energy Eq.: $0 = \dot{m}_{amm}(h_5 - h_4) + \dot{m}_{H2O}(h_{in} - h_{ex})$

$$\dot{m}_{H2O} / \dot{m}_{amm} = \frac{h_5 - h_4}{h_{in} - h_{ex}} = \frac{1442}{503.69 - 376.9} = 11.373$$

Entropy Eq.: $0 = \dot{m}_{amm}(s_4 - s_5) + \dot{m}_{H2O}(s_{in} - s_{ex}) + \dot{S}_{gen}$

$$s_{amm} = (s_5 - s_4) - (\dot{m}_{H2O} / \dot{m}_{amm})(s_{in} - s_{ex})$$
$$= 5.4971 - 0.6793 - 11.373(1.5275 - 1.1924) = \mathbf{1.007 \text{ kJ/kgK}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.72

Repeat Problem 9.43 assuming the turbine has an isentropic efficiency of 85%.

The physical components and the T-s diagram is as shown in Fig. 9.12 in the main text for one open feedwater heater. The same state numbering is used. From the Steam Tables:

State 5: (P, T) $h_5 = 4069.8$ kJ/kg, $s_5 = 7.0544$ kJ/kg K,

State 1: (P, x = 0) $h_1 = 191.81$ kJ/kg, $v_1 = 0.00101$ m^3/kg

State 3: (P, x = 0) $h_3 = 762.8$ kJ/kg, $v_3 = 0.001127$ m^3/kg

Pump P1: $w_{P1} = v_1(P_2 - P_1) = 0.00101 \times 990 = 1$ kJ/kg

$$h_2 = h_1 + w_{P1} = 192.81 \text{ kJ/kg}$$

Turbine 5-6: $s_6 = s_5 \Rightarrow h_6 = 3013.7$ kJ/kg

$$w_{T56,s} = h_5 - h_6 = 4069.8 - 3013.7 = 1056.1 \text{ kJ/kg}$$

$$w_{T56,AC} = 1056.1 \times 0.85 = 897.69 \text{ kJ/kg}$$

$$w_{T56,AC} = h_5 - h_{6AC} \Rightarrow h_{6AC} = h_5 - w_{T56,AC}$$

$$= 4069.8 - 897.69 = 3172.11 \text{ kJ/kg}$$

Feedwater Heater ($\dot{m}_{TOT} = \dot{m}_5$): $x\dot{m}_5 h_{6AC} + (1 - x)\dot{m}_5 h_2 = \dot{m}_5 h_3$

$$\Rightarrow \quad x = \frac{h_3 - h_2}{h_6 - h_2} = \frac{762.8 - 192.81}{3172.11 - 192.81} = \mathbf{0.1913}$$

To get the turbine work apply the efficiency to the whole turbine. (i.e. the first section should be slightly different).

$s_{7s} = s_{6s} = s_5 \Rightarrow x_{7s} = (7.0544 - 0.6493)/7.5009 = 0.85391$,

$h_{7s} = 191.81 + 0.85391 \times 2392.82 = 2235.1$ kJ/kg

$w_{T57,s} = h_5 - h_{7s} = 4069.8 - 2235.1 = 1834.7$ kJ/kg

$w_{T57,AC} = w_{T57,s\,T} = 1559.5 = h_5 - h_{7AC} \Rightarrow h_{7AC} = 2510.3$ kJ/kg

Find specific turbine work to get total flow rate

$$\dot{m}_{TOT} = \frac{\dot{W}_T}{x w_{T56} + (1-x) w_{T57}} = \frac{5000}{0.1913 \times 897.69 + 0.8087 \times 1559.5} = \mathbf{3.489 \text{ kg/s}}$$

$$\dot{Q}_L = \dot{m}_{TOT}(1 - x)(h_7 - h_1) = 3.489 \times 0.8087(2510.3 - 191.81) = \mathbf{6542 \text{ kW}}$$

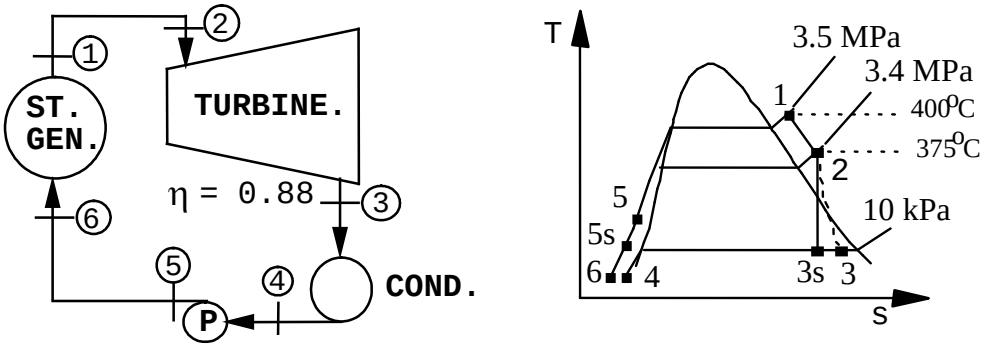
9.73

Steam leaves a power plant steam generator at 3.5 MPa, 400°C (h_1 = 3222.3 kJ/kg, s_1 = 6.8405 kJ/kg K), and enters the turbine at 3.4 MPa, 375°C (h_2 = 3165.7 kJ/kg, s_2 = 6.7675 kJ/kg K). The isentropic turbine efficiency is 88%, and the turbine exhaust pressure is 10 kPa. Condensate leaves the condenser and enters the pump at 35°C, 10 kPa. The isentropic pump efficiency is 80%, and the discharge pressure is 3.7 MPa. The feedwater enters the steam generator at 3.6 MPa, 30°C (h = 129.0 kJ/kg). Calculate the thermal efficiency of the cycle and the entropy generation for the process in the line between the steam generator exit and the turbine inlet, assuming an ambient temperature of 25°C.



1: h_1 = 3222.3 kJ/kg, s_1 = 6.8405 kJ/kg K,

2: h_2 = 3165.7 kJ/kg, s_2 = 6.7675 kJ/kg K

3s: $s_{3S} = s_2 \Rightarrow x_{3S} = 0.8157$, h_{3S} = 2143.6 kJ/kg

$w_{T,s} = h_2 - h_{3s}$ = 3165.7 - 2143.6 = 1022.1 kJ/kg

$w_{T,ac} = \eta_{T,s} w_{T,s}$ = 899.4 kJ/kg, 3ac: $h_3 = h_2 - w_{T,ac}$ = 2266.3 kJ/kg

$w_{P,s} = v_f(P_5 - P_4)$ = 0.001006(3700 - 10) = 3.7 kJ/kg

$w_{P,ac} = w_{P,s}/\eta_{P,s}$ = 4.6 kJ/kg

$q_H = h_1 - h_6$ = 3222.3 - 129.0 = 3093.3 kJ/kg

$\eta = w_{NET}/q_H$ = (899.4 - 4.6)/3093.3 = **0.289**

C.V. Line from 1 to 2: w = ∅,

Energy Eq.: $q = h_2 - h_1$ = 3165.7 - 3222.3 = - 56.6 kJ/kg

Entropy Eq.: $s_1 + s_{gen} + q/T_0 = s_2 \Rightarrow$

$s_{gen} = s_2 - s_1 - q/T_0$ = 6.7675 - 6.8405 - (-56.6/298.15) = **0.117 kJ/kg K**

9.74

Find the entropy generation per unit mass leaving the open FWH in Problem 9.40

The setup follows Fig.9.12

States : $h_2 = 419.02$, $h_6 = 2827.86$, $h_3 = 762.79$ all kJ/kg

$s_2 = 1.3068$, $s_6 = 6.6939$, $s_3 = 2.1386$ (x = 0 at 1 MPa) all kJ/kg-K

Analyze the FWH which leads to Eq.9.5:

$$y = \dot{m}_6 / \dot{m}_5 \quad \text{the extraction fraction}$$

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{762.79 - 419.02}{2827.86 - 419.02} = 0.1427$$

Entropy eq. scaled to flow at 3: $0 = y\, s_6 + (1 - y)\, s_2 - s_3 + s_{gen}$

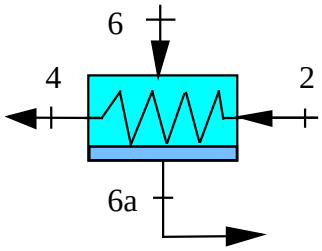
$$s_{gen} = s_3 - y\, s_6 - (1 - y)\, s_2$$
$$= 2.1386 - 0.1427 \times 6.6939 - (1 - 0.1427) \times 1.3068$$
$$= \mathbf{0.063\ kJ/kgK}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.75

Find the rate of entropy generation in the closed FWH in Problem 9.51

The schematic from Figure 9.13 has the feedwater from the pump coming at state 2 being heated by the extraction flow coming from the turbine state 6 so the feedwater leaves as saturated liquid state 4 and the extraction flow leaves as condensate state 6a.



From table B.1		h kJ/kg	s kJ/kg-K
B.1.4:	100°C, 20 MPa	h_2 = 434.04	1.2917
B.1.4:	200°C, 20 MPa	h_4 = 860.47	2.3031
B.1.3:	4 MPa, 275°C	h_6 = 2880.39	6.2145
B.1.2:	4 MPa, sat. liq.	h_{6a} = 1087.29	2.7963

C.V. Feedwater Heater

Energy Eq.: $\dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_2 h_4 + \dot{m}_6 h_{6a}$

Entropy Eq.: $0 = \dot{m}_2 s_2 + \dot{m}_6 s_6 - \dot{m}_2 s_4 - \dot{m}_6 s_{6a} + \dot{S}_{gen}$

Since all four states are known we can solve for the extraction flow rate

$$\dot{m}_6 = \dot{m}_2 \frac{h_2 - h_4}{h_{6a} - h_6} = 20 \frac{434.04 - 860.47}{1087.29 - 2880.39} \text{ kg/s} = 4.756 \text{ kg/s}$$

$$\dot{S}_{gen} = \dot{m}_2(s_4 - s_2) + \dot{m}_6 (s_{6a} - s_6)$$
$$= 20 (2.3031 - 1.2917) + 4.756 (2.7963 - 6.2145)$$
$$= 20.228 - 16.257 = \mathbf{3.971\ kW/K}$$

Cogeneration

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.76

A cogenerating steam power plant, as in Fig. 9.19, operates with a boiler output of 25 kg/s steam at 7 MPa, 500°C. The condenser operates at 7.5 kPa and the process heat is extracted as 5 kg/s from the turbine at 500 kPa, state 6 and after use is returned as saturated liquid at 100 kPa, state 8. Assume all components are ideal and find the temperature after pump 1, the total turbine output and the total process heat transfer.

Solution:

Pump 1: Inlet state is saturated liquid: $h_1 = 168.79$ kJ/kg, $v_1 = 0.001008$ m^3/kg

$$w_{P1} = \int v\, dP = v_1 (P_2 - P_1) = 0.001008(100 - 7.5) = 0.093 \text{ kJ/kg}$$

$$w_{P1} = h_2 - h_1 \Rightarrow h_2 = h_1 + w_{P1} = 168.88 \text{ kJ/kg}, \quad T_2 = \mathbf{40.3°C}$$

Turbine: $h_5 = 3410.3$ kJ/kg, $s_5 = 6.7974$ kJ/kg K

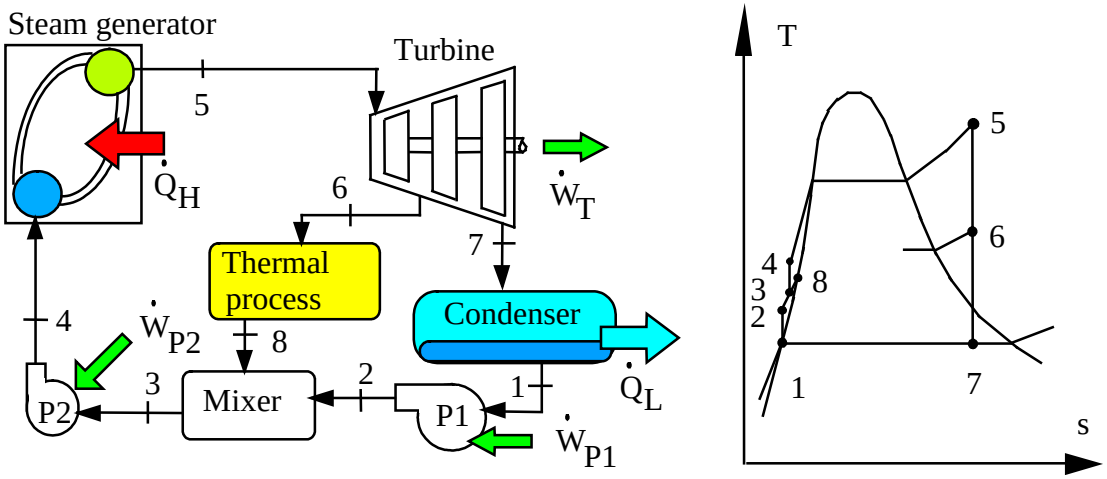
$$P_6, s_6 = s_5 \Rightarrow x_6 = 0.9952, \quad h_6 = 2738.6 \text{ kJ/kg}$$

$$P_7, s_7 = s_5 \Rightarrow x_7 = 0.8106, \quad h_7 = 2119.0 \text{ kJ/kg}$$

From the continuity equation we have the full flow from 5 to 6 and the remainder after the extraction flow is taken out flows from 6 to 7.

$$\dot{W}_T = \dot{m}_5 (h_5 - h_6) + 0.80\dot{m}_5 (h_6 - h_7) = 25 (3410.3 - 2738.6)$$
$$+ 20 (2738.6 - 2119) = 16\,792.5 + 12\,392 = \mathbf{29.185 \text{ MW}}$$

$$\dot{Q}_{proc} = \dot{m}_6(h_6 - h_8) = 5(2738.6 - 417.46) = \mathbf{11.606 \text{ MW}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.77

A steam power plant has 4 MPa, 500°C into the turbine and to have the condenser itself deliver the process heat it is run at 101 kPa. How much net power as work is produced for a process heat of 13 MW.

Solution:
From the Rankine cycle we have the states:

1: 101 kPa, $x = \emptyset$, $v_1 = 0.001043\ m^3/kg$, $h_1 = 418.6\ kJ/kg$

3: 4 MPa, 500°C , $h_3 = 3445.2\ kJ/kg$, $s_3 = 7.090\ kJ/kg\ K$

C.V. Turbine: $s_4 = s_3 \Rightarrow x_4 = (7.090 - 1.3068)/6.048 = 0.9562,$

$$h_4 = 419.02 + 0.9562 \times 2257.03 = 2577.2\ kJ/kg$$

$$w_T = h_3 - h_4 = 3445.2 - 2577.2 = 868\ kJ/kg$$

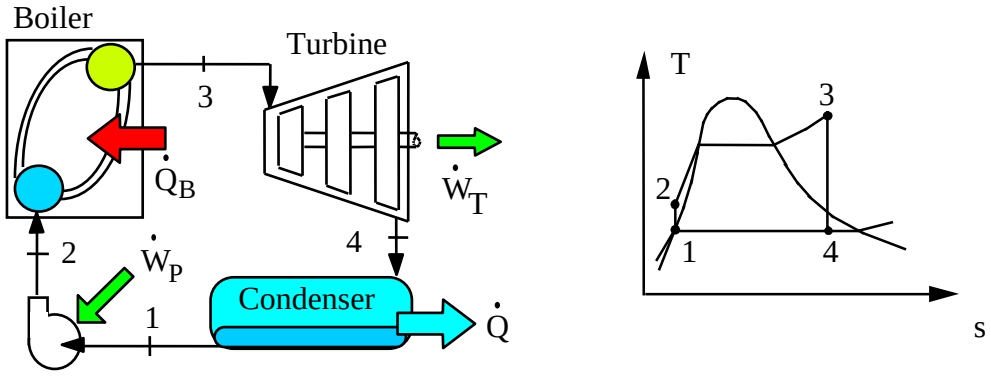
C.V. Pump: $w_P = v_1(P_2 - P_1) = 0.001043(4000 - 101) = 4.07\ kJ/kg$

$$w_P = h_2 - h_1 \Rightarrow h_2 = 419.02 + 4.07 = 423.09\ kJ/kg$$

C.V. Condenser: $q_{L,out} = h_4 - h_1 = 2577.2 - 419.02 = 2158.2\ kJ/kg$

$$\dot{m} = \dot{Q}_{proc} / q_{L,out} = 13\,000\ kW / 2158.2\ kJ/kg = 6.023\ kg/s$$

$$\dot{W}_T = \dot{m}\,(w_T - w_P) = 6.023\,(868 - 4.07) = \mathbf{5203\ kW}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

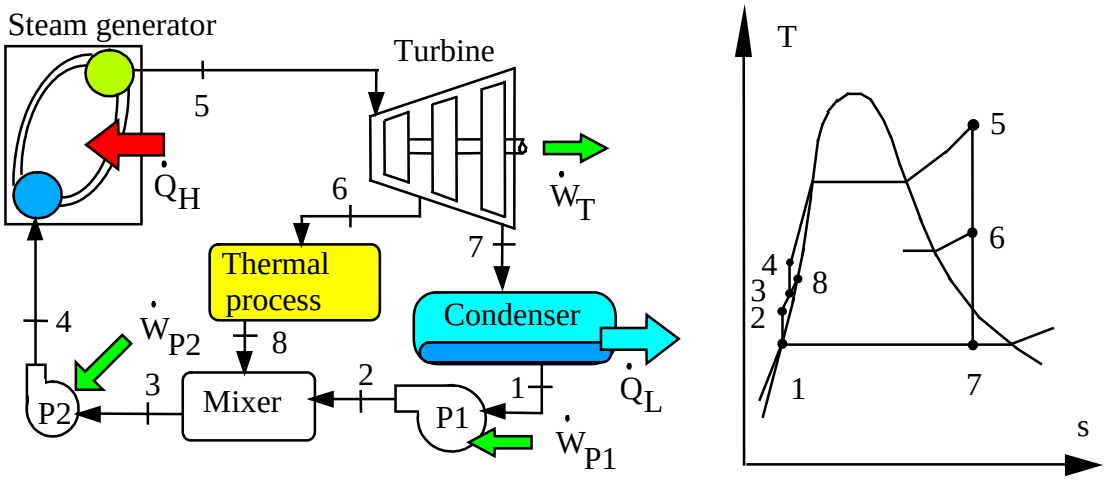
9.78

Steam must be generated at 150^{o}C for process heat in a food production facility. This is done in a combined heat and power system as extraction steam from the turbine. Assume the standard cycle has a turbine inlet of 3 MPa, 450°C and 60°C in the condenser. What pressure should be used for the extraction so there is a maximum of process heat at 150°C available and the least amount of turbine work lost?

Most energy will be available if the extraction flow can condense at 150°C. Since the flow through the turbine follows from 5 to 6 to 7 the extraction point is selected as the saturation pressure for the 150°C.

$$P_6 = P_{sat\ 150C} = \mathbf{476\ kPa}$$

As $s_5 = 7.0833 > s_{g\ 150C} = 6.8378$ kJ/kg-K, state 6 is superheated vapor.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.79

A 15 kg/s steady supply of saturated-vapor steam at 500 kPa is required for drying a wood pulp slurry in a paper mill. It is decided to supply this steam by cogeneration, that is, the steam supply will be the exhaust from a steam turbine. Water at 20°C, 100 kPa, is pumped to a pressure of 5 MPa and then fed to a steam generator with an exit at 400°C. What is the additional heat transfer rate to the steam generator beyond what would have been required to produce only the desired steam supply? What is the difference in net power?

Solution:

Desired exit State 4: P_4 = 500 kPa, sat. vap. => x_4 = 1.0, T_4 = 151.9°C

$$h_4 = h_g = 2748.7 \text{ kJ/kg}, \quad s_4 = s_g = 6.8212 \text{ kJ/kg-K}$$

Inlet State: 20°C, 100 kPa $h_1 = h_f = 83.94$ kJ/kg, $v_1 = v_f = 0.001002$ m^3/kg

Without Cogeneration; The water is pumped up to 500 kPa and then heated in the steam generator to the desired exit T.

C.V. Pump: $w_{Pw/o} = v_1(P_4 - P_1) = 0.4$ kJ/kg

$$h_2 = h_1 + w_{Pw/o} = 84.3 \text{ kJ/kg}$$

C.V. Steam Generator: $q_{w/o} = h_4 - h_2 = 2664.4$ kJ/kg

With Cogeneration; The water is pumped to 5 MPa, heated in the steam generator to 400°C and then flows through the turbine with desired exit state.

C.V. Pump: $w_{Pw} = \int v dP = v_1(P_2 - P_1) = 4.91$ kJ/kg

$$h_2 = h_1 + w_{Pw} = 88.85 \text{ kJ/kg}$$

C.V. Steam Generator: Exit 400°C, 5 MPa => $h_3 = 3195.64$ kJ/kg

$$q_w = h_3 - h_2 = 3195.64 - 88.85 = 3106.8 \text{ kJ/kg}$$

C.V.: Turbine, Inlet and exit states given

$$w_t = h_3 - h_4 = 3195.64 - 2748.7 = 446.94 \text{ kJ/kg}$$

Comparison

Additional Heat Transfer: $q_w - q_{w/o} = 3106.8 - 2664.4 = 442.4$ kJ/kg

$$\dot{Q}_{extra} = \dot{m}(q_w - q_{w/o}) = \mathbf{6636\ kW}$$

Difference in Net Power: $w_{diff} = (w_t - w_{Pw}) + w_{Pw/o}$,

$$w_{diff} = 446.94 - 4.91 + 0.4 = 442.4 \text{ kJ/kg}$$

$$\dot{W}_{diff} = \dot{m} w_{diff} = \mathbf{6636\ kW}$$

By adding the extra heat transfer at the higher pressure and a turbine all the extra heat transfer can come out as work (it appears as a 100% efficiency)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.80

In a cogenerating steam power plant the turbine receives steam from a high-pressure steam drum (h = 3445.9 kJ/kg, s = 6.9108 kJ/kgK) and a low-pressure steam drum (h = 2855.4 kJ/kg, s = 7.0592 kJ/kgK) as shown in Fig. P9.80. For the turbine calculation assume a mass weighted average entropy and neglect entropy generation by mixing. The condenser is made as two closed heat exchangers used to heat water running in a separate loop for district heating. The high-temperature heater adds 30 MW and the low-temperature heater adds 31 MW to the district heating water flow. Find the power cogenerated by the turbine and the temperature in the return line to the deaerator.

Solution:

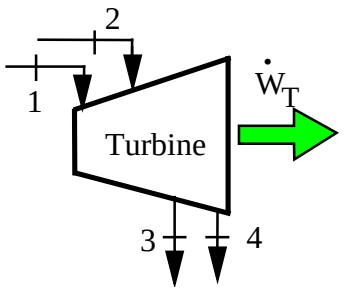
Inlet states from Table B.1.3

$h_1 = 3445.9$ kJ/kg, $s_1 = 6.9108$ kJ/kg K

$h_2 = 2855.4$ kJ/kg, $s_2 = 7.0592$ kJ/kg K

$\dot{m}_{TOT} = \dot{m}_1 + \dot{m}_2 = 27$ kg/s

Assume a reversible turbine and the two flows can mix without s generation.



Energy Eq.4.10: $\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3 + \dot{m}_4 h_4 + \dot{W}_T$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 = \dot{m}_{TOT} s_{mix} \Rightarrow s_{MIX} = 6.9383$ kJ/kg K

State 3: $s_3 = s_{MIX} \Rightarrow h_3 = 2632.4$ kJ/kg, $x_3 = 0.966$

State 4: $s_4 = s_{MIX} \Rightarrow h_4 = 2413.5$ kJ/kg, $x_4 = 0.899$

$$\dot{W}_T = 22 \times 3445.9 + 5 \times 2855.4 - 13 \times 2632.4 - 14 \times 2413.5$$
$$= 22\,077 \text{ kW} = \mathbf{22\ MW}$$

District heating line $\dot{Q}_{TOT} = \dot{m}(h_{95} - h_{60}) = 60\,935$ kW

OK, this matches close enough

C.V. Both heaters: $\dot{m}_3 h_3 + \dot{m}_4 h_4 - \dot{Q}_{TOT} = \dot{m}_{TOT} h_{EX}$

$13 \times 2632.4 - 14 \times 2413.5 - 60\,935 = 7075.2 = 27 \times h_{EX}$

$h_{EX} = 262 \approx h_f \Rightarrow T_{EX} = \mathbf{62.5°C}$

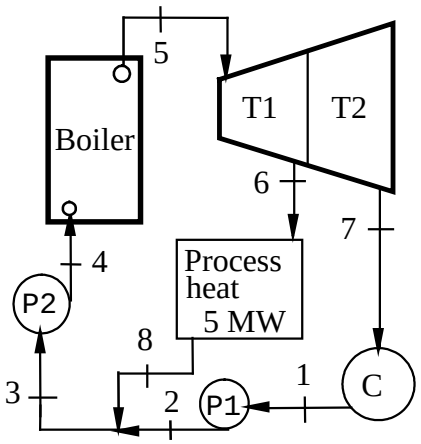
Remark: We could have computed the expansion from state 1 to P_2 followed by a mixing process to find a proper state 2a from which we expand down to P_3 and P_4

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.81

A boiler delivers steam at 10 MPa, 550°C to a two-stage turbine as shown in Fig. 9.19. After the first stage, 25% of the steam is extracted at 1.4 MPa for a process application and returned at 1 MPa, 90°C to the feedwater line. The remainder of the steam continues through the low-pressure turbine stage, which exhausts to the condenser at 10 kPa. One pump brings the feedwater to 1 MPa and a second pump brings it to 10 MPa. Assume all components are ideal. If the process application requires 5 MW of power, how much power can then be cogenerated by the turbine?

Solution:



5: $h_5 = 3500.9$, $s_5 = 6.7561$ kJ/kg K

First ideal turbine T1

6: $s_6 = s_5 \Rightarrow h_6 = 2932.4$ kJ/kg

$w_{T1} = h_5 - h_6 = 568.5$ kJ/kg

Ideal turbine T2

State 7: $s_7 = s_6 = s_5$

$$x = \frac{6.7561 - 0.6492}{7.501} = 0.8141$$

$\Rightarrow \quad h_7 = 2139.9$ kJ/kg

$w_{T2} = h_6 - h_7 = 2932.4 - 2139.9 = 792.5$ kJ/kg

Now do the process heat requirement

8: $h_8 = 377.3$ kJ/kg, approx. from the compressed liq. Table at 500 kPa

$q_{PROC} = h_6 - h_8 = 2932.4 - 377.3 = 2555.1$ kJ/kg

$\dot{m}_6 = \dot{Q}/q_{PROC} = 5000 / 2555.1 = 1.9569$ kg/s $= 0.25\ \dot{m}_{TOT}$

$\Rightarrow \quad \dot{m}_{TOT} = \dot{m}_5 = 7.8275$ kg/s, $\dot{m}_7 = \dot{m}_5 - \dot{m}_6 = 5.8706$ kg/s

$$\dot{W}_T = \dot{m}_5 h_5 - \dot{m}_6 h_6 - \dot{m}_7 h_7$$
$$= 7.8275 \times 3500.9 - 1.9569 \times 2932.4 - 5.8706 \times 2139.9$$
$$= \mathbf{9102\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.82

A smaller power plant produces 25 kg/s steam at 3 MPa, 600°C, in the boiler. It cools the condenser to an exit of 45°C and the cycle is shown in Fig. P9.82. An extraction is done at 500 kPa to an open feedwater heater, in addition a steam supply of 5 kg/s is taken out and not returned. The missing 5 kg/s water is added to the feedwater heater from a 20°C, 500 kPa source. Find the needed extraction flow rate to cover both the feedwater heater and the steam supply. Find the total turbine power output.

Solution:

The states properties from Tables B.1.1 and B.1.3

1: 45°C, x = 0: $h_1 = 188.42$ kJ/kg, $v_1 = 0.00101$ m^3/kg, $P_{sat} = 9.59$ kPa

5: 3.0 MPa, 600°C: $h_5 = 3682.34$ kJ/kg, $s_5 = 7.5084$ kJ/kg K

3: 500 kPa, x = 0: $h_3 = 640.21$ kJ/kg 8: $h_8 = 84.41$ kJ/kg

6: 500 kPa, $s_6 = s_5$ from HP turbine, $h_6 = 3093.26$ kJ/kg

C.V. Pump 1. Reversible and adiabatic. Incompressible so v = constant

Energy: $w_{p1} = h_2 - h_1 = \int v\, dP = v_1(P_2 - P_1)$

$= 0.00101\ (500 - 9.6) = 0.495$ kJ/kg

$h_2 = h_1 + w_{p1} = 188.42 + 0.495 = 188.915$ kJ/kg

C.V. Turbine sections

Entropy Eq.: $s_7 = s_5 = 7.5084$ kJ/kg K => two-phase state

$s_7 = 7.5084 = 0.6386 + x_7 \times 7.5261 \Rightarrow x_7 = 0.9128$

$h_7 = 188.42 + 0.9128 \times 2394.77 = 2374.4$ kJ/kg

C.V. Feedwater heater, including the make-up water flow, $y = \dot{m}_6/\dot{m}_5$.

Energy eq.: $\dot{m}_8 h_8 + (\dot{m}_5 - \dot{m}_6)h_2 + (\dot{m}_6 - \dot{m}_8)h_6 = \dot{m}_5 h_3$

Divide by $\dot{m}_5$ and solve for y

$$y = \frac{h_3 - h_2 + (h_6 - h_8)\,\dot{m}_8/\dot{m}_5}{h_6 - h_2} = \frac{640.21 - 188.915 + (3093.26 - 84.41)5/25}{3093.26 - 188.915}$$

$= 0.3626$

$\dot{m}_6 = y\,\dot{m}_5 = 0.3626 \times 25 =$ **9.065 kg/s**

C.V. Turbine energy equation

$\dot{W}_T = \dot{m}_5 h_5 - \dot{m}_6 h_6 - \dot{m}_7 h_7$

$= 25 \times 3682.34 - 9.065 \times 3093.26 - 16.935 \times 2374.4$

= 26 182 kW

Refrigeration cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.83

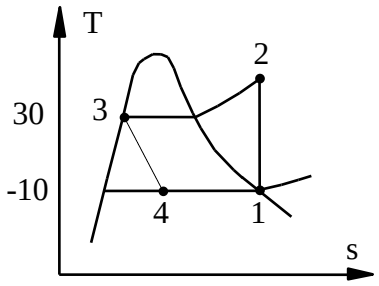
A refrigeration cycle as in Fig. 9.23 can be used for cooling or for heating purposes using one of the two heat exchangers. Suppose a refrigerator should cool meat at -10°C in a 30°C hot kitchen what are the minimum high and maximum low pressures in the cycle if the working substance is a) R-134a or b) R-410A.

Ideal refrigeration cycle

$T_{cond} = 30°C$

$T_{evap} = -10^{o}C = T_1$

Properties from Tbl. B.4 + B.5



The condensing temperature, T_3, must be minimum 30°C to move a heat transfer to the kitchen air. The low temperature in the evaporator must at most -10°C to be able to extract energy from the cold space.

R-134a, B.5:

$$P_{hi} \geq P_3 = P_{sat}(30°C) = 771 \text{ kPa}$$
$$P_{low} \leq P_1 = P_{sat}(-10°C) = 201.7 \text{ kPa}$$

R-410A, B.4:

$$P_{hi} \geq P_3 = P_{sat}(30°C) = 1885 \text{ kPa}$$
$$P_{low} \leq P_1 = P_{sat}(-10°C) = 573 \text{ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.84

A refrigerator with R-134a as the working fluid has a minimum temperature of –10°C and a maximum pressure of 1 MPa. Assume an ideal refrigeration cycle as in Fig. 9.23. Find the specific heat transfer from the cold space and that to the hot space, and the coefficient of performance.

Solution:

Exit evaporator sat. vapor –10°C from B.5.1: $h_1 = 392.28$, $s_1 = 1.7319$ kJ/kgK

Exit condenser sat. liquid 1 MPa from B.5.1: $h_3 = 255.60$ kJ/kg

Compressor: $s_2 = s_1$ & P_2 from B.5.2 $\Rightarrow$ $h_2 \approx 425.68$ kJ/kg

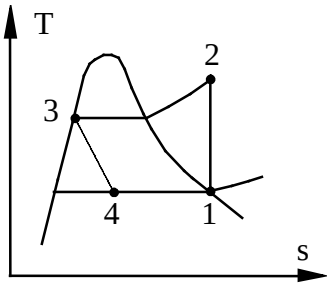
Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 392.28 - 255.60 =$ **136.7 kJ/kg**

Condenser: $q_H = h_2 - h_3 = 425.68 - 255.60 =$ **170.1 kJ/kg**

COP: $\beta = q_L/w_c = q_L/(q_H - q_L) =$ **4.09**

Ideal refrigeration cycle
$P_{cond} = P_3 = P_2 = 1$ MPa
$T_{evap} = -10^oC = T_1$

Properties from Table B.5



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.85

Repeat the previous Problem with R-410A as the working fluid. Will that work in an ordinary kitchen?

Solution:

Exit evaporator sat. vapor –10°C from B.4.1: $h_1 = 275.78$, $s_1 = 1.0567$ kJ/kgK

Exit condenser sat. liquid 1 MPa from B.4.1: $h_3 = 68.92$ kJ/kg

Compressor: $s_2 = s_1$ & P_2 from B.4.2 $\Rightarrow$ $h_2 \approx 290.81$ kJ/kg

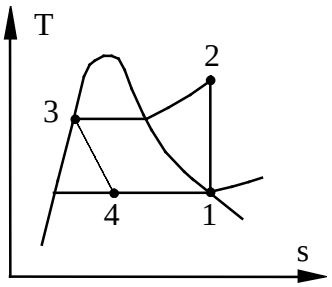
Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 275.78 - 68.92 =$ **206.9 kJ/kg**

Condenser: $q_H = h_2 - h_3 = 290.81 - 68.92 =$ **221.9 kJ/kg**

COP: $\beta = q_L/w_c = q_L/(q_H - q_L) =$ **13.8**

Ideal refrigeration cycle
$P_{cond} = P_3 = P_2 = 1$ MPa
$T_{evap} = -10^oC = T_1$

Properties from Table B.4



The 1 MPa is too small, the condensing temperature is 7.25°C and the q_H in the condenser can not be rejected to a kitchen normally at 20°C.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.86

The natural refrigerant carbon dioxide has a fairly low critical temperature. Find the high temperature, the condensing temperature and the COP if it is used in a standard cycle with high and low pressures of 6 MPa and 3 MPa.

Exit evaporator x = 1 and 3 MPa from B.3.2:

$$h_1 = 320.71 \text{ kJ/kg}, \quad s_1 = 1.2098 \text{ kJ/kgK}$$

Exit condenser saturated liquid 6 MPa from B.3.1:

$$T_3 = \mathbf{22°C}, \quad h_3 = 150 \text{ kJ/kg}$$

Exit compressor: 6 MPa, $s = s_1$, so interpolate in B.3.2

$$T_2 = \mathbf{45.9°C}, \quad h_2 = 348.24 \text{ kJ/kg}$$

COP: $$\beta = \frac{q_L}{w_c} = \frac{h_1 - h_3}{h_2 - h_1} = \mathbf{6.2}$$

Remark: The condensing T is too low for a standard refrigerator it can not push the heat transfer to the room which may be hotter than that.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.87

Consider an ideal refrigeration cycle that has a condenser temperature of 45°C and an evaporator temperature of –15°C. Determine the coefficient of performance of this refrigerator for the working fluids R-134a and R-410A.

Solution:

Ideal refrigeration cycle

$T_{cond} = 45^oC = T_3$

$T_{evap} = -15^oC = T_1$

	Property for:	**R-134a, B.5**	**R-410A, B.4**
Compressor	h_1, kJ/kg	389.2	273.9
	$s_2 = s_1$, kJ/kg K	1.7354	1.0671
	P_2, MPa	1.16	2.7283
	T_2, ^oC	51.8*	71.5**
	h_2, kJ/kg	429.9*	322.72**
	$w_C = h_2 - h_1$	40.7	48.82
Exp. valve	$h_3 = h_4$, kJ/kg	264.11	133.61
Evaporator	$q_L = h_1 - h_4$	125.1	140.29
	$\beta = q_L/w_C$	**3.07**	**2.87**

* For state 2 an interpolation between 1 and 1.2 MPa is needed for 1.16 MPa:

At 1 MPa, s = 1.7354 : T = 45.9 °C and h = 426.8 kJ/kg

At 1.2 MPa, s = 1.7354 : T = 53.3 °C and h = 430.7 kJ/kg

** For state 2 an interpolation between 2 and 3 MPa is needed for 2.728 MPa:

At 2 MPa, s = 1.0671 : T = 54.68 °C and h = 313.942 kJ/kg

At 3 MPa, s = 1.0671 : T = 77.80 °C and h = 326.0 kJ/kg

It would make more sense to use the CATT3 program.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.88

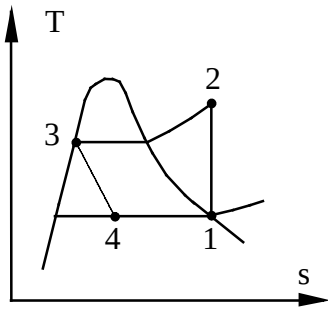
Do problem 9.87 with ammonia as the working fluid.

Solution:

Ideal refrigeration cycle

$T_{cond} = 45^oC = T_3$

$T_{evap} = -15^oC = T_1$



State 1: $h_1 = 1424.6$ kJ/kg, $s_1 = 5.5397$ kJ/kg-K

State 2: $s = s_1$, $P_2 = 1782$ kPa, $T_2 = 135.1^oC$, $h_2 = 1731.3$ kJ/kg

For state 2 an interpolation between 1.6 and 2 MPa is needed for 1.782 MPa:

At 1.6 MPa, s = 5.5397 : T = 126.0 °C and h = 1712.2 kJ/kg

At 2.0 MPa, s = 5.5397 : T = 146.1°C and h = 1754.1 kJ/kg

It would make more sense to use the CATT3 program.

$$w_C = h_2 - h_1 = 1731.3 - 1424.6 = 306.7 \text{ kJ/kg}$$

State 3-4: $h_4 = h_3 = 396.3$ kJ/kg $q_L = h_1 - h_4 = 1028.3$ kJ/kg

$$\beta = q_L/w_C = \mathbf{3.353}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.89

A refrigerator receives 500 W of electrical power to the compressor driving the cycle flow of R-134a. The refrigerator operates with a condensing temperature of 40°C and a low temperature of -5°C. Find the COP for the cycle and its cooling capacity.

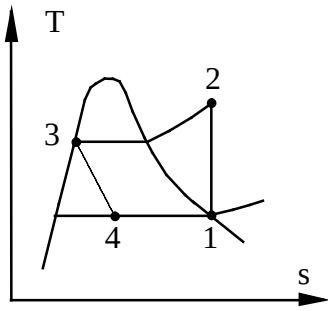
Solution:

Ideal refrigeration cycle

$T_{cond} = 40^oC = T_3$

$T_{evap} = -5^oC = T_1$

Properties from Table B.5



Exit evaporator sat. vapor –5°C from B.5.1: $h_1 = 395.3$ kJ/kg, $s_1 = 1.7288$ kJ/kgK

Compressor: $s_2 = s_1$ & P_2 from B.5.2 $\Rightarrow$ $T_2 = 45^oC$, $h_2 \approx 425$ kJ/kg

$w_C = h_2 - h_1 = 425 - 395.3 = 29.7$ kJ/kg

Exit condenser sat. liquid $P_2 = P_3 = 1017$ kPa from B.5.1: $h_3 = 256.50$ kJ/kg

Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 395.3 - 256.50 = 138.8$ kJ/kg

Condenser: $q_H = h_2 - h_3 = 425 - 256.5 = 168.5$ kJ/kg

COP: $\beta = q_L/w_c = q_L/(q_H - q_L) = 138.8 / 29.7 =$ **4.67**

$\dot{Q}_L = \beta \dot{W} = 4.67 \times 500$ W $= 2335$ W $=$ **2.3 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.90

A new air-conditioner using R-410A is used in heat pump mode. The high pressure is 2000 kPa and the low pressure is 400 kPa. It warms a house at 20°C driven by an electric power input of 2 kW in an ambient at -5°C. Find the COP, the heating rate and the rate of entropy generation for the heat pump.

Exit evaporator sat. vapor 400 kPa from B.4.2: $h_1 = 271.9$, $s_1 = 1.0779$ kJ/kgK

Exit condenser sat. liquid 2 MPa (32.31^{o}C) from B.4.1: $h_3 = 110.21$ kJ/kg

Compressor: $s_2 = s_1$ & P_2 from B.4.2 $\Rightarrow$ $h_2 \approx 317.43$ kJ/kg

Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 271.9 - 110.21 = 161.69$ kJ/kg

Condenser: $q_H = h_2 - h_3 = 317.43 - 110.21 = 207.22$ kJ/kg

Compressor: $w_c = h_2 - h_1 = 317.43 - 271.9 = 45.53$ kJ/kg

COP: $\beta = q_H/w_c = 207.22/45.53 =$ **4.55**

Heating rate: $\dot{Q}_H = \beta \dot{W} = 4.55 \times 2 =$ **9.1 kW**

CV: The A/C unit including the two heat exchangers.

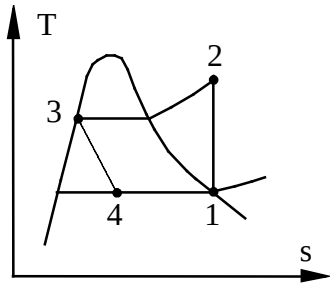
Energy: $0 = q_L - q_H + w_c$

Entropy: $0 = q_L/T_{amb} - q_H/T_{house} + s_{gen}$

$$\dot{S}_{gen} = \dot{Q}_H/T_{house} - \dot{Q}_L/T_{amb} = \frac{9.1 \text{ kW}}{293.15 \text{ K}} - \frac{(9.1 - 2) \text{ kW}}{268.15 \text{ K}} = \mathbf{0.00456 \text{ kW/K}}$$

Ideal refrigeration cycle
$P_{cond} = P_3 = P_2 = 2$ MPa
$T_{evap} = -19.98^oC = T_1$

Properties from Table B.4



Comment: The entropy generation does not include the heat loss from the house to the ambient (this is why we heat a house) if that was included then q_L comes in at T_{amb} and q_H leaves at T_{amb} so the total entropy generation becomes w/T_{amb}.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.91

Consider the heat pump in the previous problem. Repeat the questions for a system with an actual compressor with an exit state of 2000 kPa, 65°C.

Exit evaporator sat. vapor 400 kPa from B.4.2: $h_1 = 271.9$, $s_1 = 1.0779$ kJ/kgK

Ideal Compressor: $s_2 = s_1$ & P_2 from B.4.2 $\Rightarrow$ $h_2 \approx 317.43$ kJ/kg

$w_c = h_2 - h_1 = 317.43 - 271.9 = 45.53$ kJ/kg

Actual compressor exit: $h_{2\,ac} = 326.27$ kJ/kg, $s_2 = 1.1043$ kJ/kg-K

Actual Compressor: $w_{c\,ac} = h_{2\,ac} - h_1 = 326.27 - 271.9 = 54.37$ kJ/kg

Exit condenser sat. liquid 2 MPa (32.31°C) from B.4.1: $h_3 = 110.21$ kJ/kg

Condenser: $q_H = h_{2\,ac} - h_3 = 326.27 - 110.21 = 216.06$ kJ/kg

Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 271.9 - 110.21 = 161.69$ kJ/kg

COP: $\beta = q_H/w_{c\,ac} = 216.06/54.37 =$ **3.974**

Heating rate: $\dot{Q} = \beta \dot{W} = 3.974 \times 2$ kW = **7.95 kW**

CV: The A/C unit including the two heat exchangers.

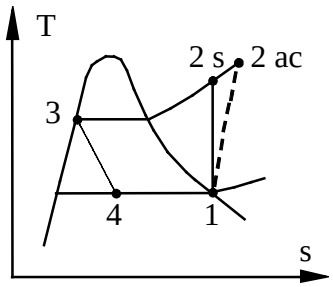
Energy: $0 = q_L - q_H + w_c$

Entropy: $0 = q_L/T_{amb} - q_H/T_{house} + s_{gen}$

$$\dot{S}_{gen} = \dot{Q}_H/T_{house} - \dot{Q}_L/T_{amb} = \frac{7.95 \text{ kW}}{293.15 \text{ K}} - \frac{(7.95 - 2) \text{ kW}}{268.15 \text{ K}} = \mathbf{0.00493\ kW/K}$$

Actual refrigeration cycle
$P_{cond} = P_3 = P_2 = 2$ MPa
$T_{evap} = -19.98^oC = T_1$

Properties from Table B.4



Comment: The entropy generation does not include the heat loss from the house to the ambient (this is why we heat a house) if that was included then q_L comes in at T_{amb} and q_H leaves at T_{amb} so the total entropy generation becomes w/T_{amb}.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.92

A heat pump for heat upgrade uses ammonia with a low temperature of 25°C and a high pressure of 5000 kPa. If it receives 1 MW of shaft work what is the rate of heat transfer at the high temperature?

State 1: Table B.2.1 $h_1 = 1463.5$ kJ/kg, $s_1 = 5.0293$ kJ/kgK

State 3: Table B.2.1 $h_3 = h_f = 631.9$ kJ/kg

Entropy compressor: $s_2 = s_1$ => $T_2 = 156^{o}$C, $h_2 = 1709.1$ kJ/kg

Energy eq. compressor: $w_C = h_2 - h_1 = 245.6$ kJ/kg

Energy condenser: $q_H = h_2 - h_3 = 1077.2$ kJ/kg

Scaling to power input: $$\dot{Q}_H = q_H \frac{\dot{W}_{IN}}{w_C}$$

$$= 1077.2 \text{ kJ/kg} \times \frac{1000}{245.6} \text{ kg/s}$$

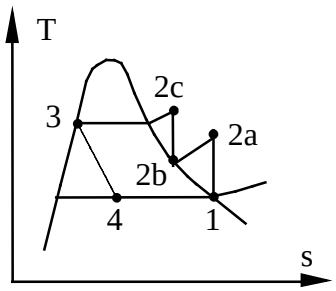
$$= \mathbf{4386\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.93

Reconsider the heat pump in the previous problem. Assume the compressor is split into two, first compress to 2000 kPa, then take heat transfer out at constant P to reach saturated vapor then compress to the 5000 kPa. Find the two rates of heat transfer, at 2000 kPa and at 5000 kPa for a total of 1 MW shaft work input.

Ideal heat pump
$T_{evap} = 25^oC = T_1$



State 1: Table B.2.1 $h_1 = 1463.5$ kJ/kg, $s_1 = 5.0293$ kJ/kgK

State 3: Table B.2.1 $h_3 = h_f = 631.9$ kJ/kg

Entropy compressor 1: $s_{2a} = s_1$ => $T_{2a} = 75.3^oC$, $h_{2a} = 1559.1$ kJ/kg

Energy eq. compressor 1: $w_{C1} = h_{2a} - h_1 = 1559.1 - 1463.5 = 95.6$ kJ/kg

Exit heat exchanger 1: $h_{2b} = 1471.5$ kJ/kg, $s_{2b} = 4.768$ kJ/kgK

Entropy compressor 2: $s_{2c} = s_{2b}$ => $T_{2c} = 124.3^oC$, $h_{2c} = 1601.37$ kJ/kg

Energy eq. compressor 2: $w_{C2} = h_{2c} - h_{2b} = 1601.37 - 1471.5 = 129.87$ kJ/kg

Total power input: $\dot{W}_{IN} = \dot{m}\,(w_{C1} + w_{C2}) \Rightarrow$

$$\dot{m} = \frac{\dot{W}_{IN}}{w_{C1} + w_{C2}} = \frac{1000}{95.6 + 129.87} = 4.4352 \text{ kg/s}$$

Heat exchanger 1: $\dot{Q}_{H1} = \dot{m}(h_{2a} - h_{2b}) = 4.4352(1559.1\text{-}1471.5) =$ **388.5 kW**

Heat exchanger 2: $\dot{Q}_{H2} = \dot{m}(h_{2c} - h_3) = 4.4352(1601.37\text{-}631.9) =$ **4299.8 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.94

A refrigerator with R-134a as the working fluid has a minimum temperature of –10°C and a maximum pressure of 1 MPa. The actual adiabatic compressor exit temperature is 50°C. Assume no pressure loss in the heat exchangers. Find the specific heat transfer from the cold space and that to the hot space, the coefficient of performance and the isentropic efficiency of the compressor.

Solution:

State 1: Inlet to compressor, sat. vapor -10°C,

$h_1 = 392.28$, $s_1 = 1.7319$ kJ/kgK

State 2: Actual compressor exit, $h_{2AC} = 431.24$ kJ/kg

State 3: Exit condenser, sat. liquid 1 MPa, $h_3 = 255.60$ kJ/kg

State 4: Exit valve, $h_4 = h_3$

C.V. Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 392.28 - 255.60 =$ **136.7 kJ/kg**

C.V. Ideal Compressor: $w_{C,S} = h_{2,S} - h_1$, $s_{2,S} = s_1$

State 2s: 1 MPa, s = 1.7319 kJ/kg K; $T_{2,S} = 44.9$°C, $h_{2,S} = 425.7$ kJ /kg

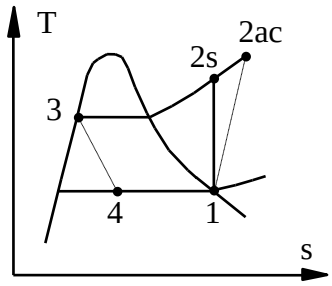
$w_{C,S} = h_{2,S} - h_1 = 33.42$ kJ/kg

C.V. Actual Compressor: $w_C = h_{2,AC} - h_1 = 38.96$ kJ/kg

$$\beta = \frac{q_L}{w_C} = \mathbf{3.51}, \qquad \eta_C = w_{C,S}/w_C = \mathbf{0.858}$$

C.V. Condenser: $q_H = h_{2,AC} - h_3 =$ **186.3 kJ/kg**

Ideal refrigeration cycle with actual compressor
$P_{cond} = P_3 = P_2 = 1$ MPa
$T_{2AC} = 50^oC$
$T_{evap} = -10^oC = T_1$
Properties from Table B.5



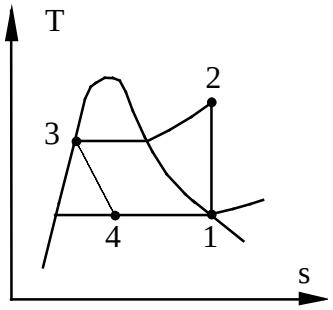
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.95

An air-conditioner in the airport of Timbuktu runs a cooling system using R-410A with a high pressure of 1800 kPa and a low pressure of 200 kPa. It should cool the desert air at 45°C down to 15°C. Find the cycle COP. Will the system work?

Solution:

Ideal refrigeration cycle
$P_{cond} = P_2 = P_3 = 1800$ kPa
$P_{evap} = P_1$



State 1: $T_1 = -37.0^oC$, $h_1 = 264.27$ kJ/kg, $s_1 = 1.1192$ kJ/kg-K

State 2: $P_2 = 1800$ kPa, $s_2 = s_1$: $T_2 = 63.6^oC$, $h_2 = 327.9$ kJ/kg

$w_C = h_2 - h_1 = 327.9 - 264.27 = 63.63$ kJ/kg

State 3-4: $P_4 = P_3$, $x_3 = 0$: $T_3 = 28.22^oC$, $h_4 = h_3 = 103.096$ kJ/kg

$q_L = h_1 - h_4 = 264.27 - 103.096 = 161.17$ kJ/kg

$\beta = q_L/w_C = 161.17/63.63 =$ **2.53**

The heat rejection from 2-3 to ambient at 45°C has $T_3 = 28.22^oC$ not hot enough so the system will **not work**. The high pressure must be so also $T_3 > 45^oC$.

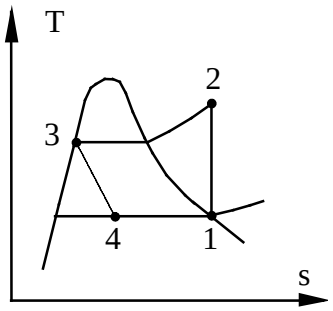
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.96

A heat pump uses R410a with a high pressure of 3000 kPa and an evaporator operating at -10°C so it can absorb energy from underground water layers at 4°C. Find the COP and the temperature it can deliver energy at.

Solution:

Ideal refrigeration cycle
R-410A
$P_{cond} = P_2 = P_3 = 3000$ kPa
$T_{evap} = -10^oC = T_1$



State 1: $h_1 = 275.78$ kJ/kg, $s_1 = 1.0567$ kJ/kg-K

State 2: P_2, $s_2 = s_1$: $T_2 = 75.3^oC$, $h_2 = 322.43$ kJ/kg

$w_C = h_2 - h_1 = 322.43 - 275.78 = 46.65$ kJ/kg

State 3-4: $h_3 = h_4$, $x_3 = 0$: $T_3 = 49.07^oC$, $h_4 = h_3 = 141.78$ kJ/kg

$q_H = h_2 - h_3 = 322.43 - 141.78 = 180.65$ kJ/kg

$$\beta = q_H/w_C = \frac{180.65}{46.65} = \mathbf{3.87}$$

It can deliver heat at about $49^oC = T_3$ (minus a ΔT for the heat transfer rate) a smaller amount of heat is delivered between T_2 and T_3**.**

9.97

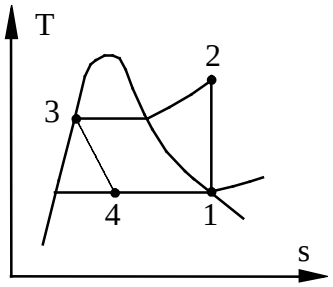
Consider an ideal heat pump that has a condenser temperature of 50°C and an evaporator temperature of 0°C. Determine the coefficient of performance of this heat pump for the working fluids R-134a and ammonia.

Solution:

Ideal heat pump

$T_{cond} = 50^{o}C = T_3$

$T_{evap} = 0^{o}C = T_1$



C.V.	Property for: From Table:	R-134a B.5	NH_3 B.2
	h_1, kJ/kg	398.36	1442.32
Compressor	$s_2 = s_1$, kJ/kgK	1.7262	5.3313
	P_2, MPa	1.3181	2.0333
	T_2, ^{o}C	55.1	115.6
	h_2, kJ/kg	429.55	1672.84
	$w_C = h_2 - h_1$	31.19	230.52
Exp. valve	$h_3 = h_4$, kJ/kg	271.83	421.58
Condenser	$q_H = h_2 - h_3$	157.72	1251.26
	$\beta' = q_H/w_C$	**5.06**	**5.428**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.98

A refrigerator in a meat warehouse must keep a low temperature of -15°C and the outside temperature is 20°C. It uses ammonia as the refrigerant which must remove 5 kW from the cold space. Find the flow rate of the ammonia needed assuming a standard vapor compression refrigeration cycle with a condenser at 20°C.

Solution:

Basic refrigeration cycle: $T_1 = T_4 = -15°C$, $T_3 = 20°C$

Table B.3: $h_4 = h_3 = 274.3$ kJ/kg; $h_1 = h_g = 1424.6$ kJ/kg

$$\dot{Q}_L = \dot{m}_{amm} \times q_L = \dot{m}_{amm} (h_1 - h_4)$$

$$q_L = 1424.6 - 274.3 = 1150.3 \text{ kJ/kg}$$

$$\dot{m}_{amm} = 5.0 \text{ kW}/ 1150.3 \text{ kJ/kg} = \mathbf{0.00435 \text{ kg/s}}$$

Ideal refrigeration cycle

$T_{cond} = 20^oC$

$T_{evap} = -15^oC = T_1$

Properties from Table B.2

9.99

A refrigerator has a steady flow of R-410A as saturated vapor at –20°C into the adiabatic compressor that brings it to 1400 kPa. After the compressor, the temperature is measured to be 60°C. Find the actual compressor work and the actual cycle coefficient of performance.

Solution:

Table B.4.1: $h_1 = 271.89$ kJ/kg, $s_1 = 1.0779$ kJ/kg K

$P_2 = P_3 = 1400$ kPa, $T_3 = 18.88$°C, $h_4 = h_3 = h_f = 87.45$ kJ/kg

$h_{2\,ac} = 330.07$ kJ/kg

C.V. Compressor (actual)

Energy Eq.: $w_{C\,ac} = h_{2\,ac} - h_1 = 330.07 - 271.89 =$ **58.18 kJ/kg**

C.V. Evaporator

Energy Eq.: $q_L = h_1 - h_4 = h_1 - h_3 = 271.89 - 87.45 = 184.44$ kJ/kg

$$\beta = \frac{q_L}{w_{C\,ac}} = \frac{184.44}{58.18} = \mathbf{3.17}$$

Ideal refrigeration cycle
with actual compressor

$T_{cond} = 18.88^oC = T_{sat\ 1400\ kPa}$

$T_2 = 60^oC$

$T_{evap} = -20^oC = T_1$

Properties from Table B.4

9.100

The air conditioner in a car uses R-134a and the compressor power input is 1.5 kW bringing the R-134a from 201.7 kPa to 1200 kPa by compression. The cold space is a heat exchanger that cools atmospheric air from the outside 30°C down to 10°C and blows it into the car. What is the mass flow rate of the R-134a and what is the low temperature heat transfer rate. How much is the mass flow rate of air at 10°C?

Standard Refrigeration Cycle

Table B.5: $h_1 = 392.28$ kJ/kg; $s_1 = 1.7319$ kJ/kg K; $h_4 = h_3 = 266$ kJ/kg

C.V. Compressor (assume ideal)

$\dot{m}_1 = \dot{m}_2$ $\quad w_C = h_2 - h_1$; $\quad s_2 = s_1 + s_{gen}$

P_2, $s = s_1$ => $h_2 = 429.5$ kJ/kg => $w_C = 37.2$ kJ/kg

$\dot{m}\, w_C = \dot{W}_C$ => $\dot{m} = 1.5 / 37.2 =$ **0.0403 kg/s**

C.V. Evaporator

$\dot{Q}_L = \dot{m}(h_1 - h_4) = 0.0405(392.28 - 266) =$ **5.21 kW**

C.V. Air Cooler

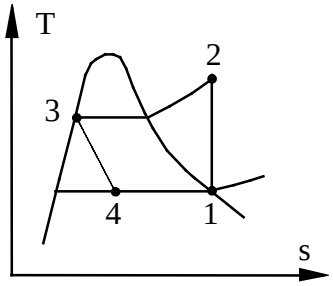
$\dot{m}_{air}\Delta h_{air} = \dot{Q}_L \approx \dot{m}_{air} C_p \Delta T$

$\dot{m}_{air} = \dot{Q}_L / (C_p \Delta T) = 5.21 / (1.004 \times 20) =$ **0.26 kg / s**

Ideal refrigeration cycle

$P_{cond} = 1200$ kPa $= P_3$

$P_{evap} = 201.7$ kPa $= P_1$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.101

A refrigerator in a laboratory uses R-134a as the working substance. The high pressure is 1200 kPa, the low pressure is 165 kPa, and the compressor is reversible. It should remove 500 W from a specimen currently at –10°C (not equal to T_L in the cycle) that is inside the refrigerated space. Find the cycle COP and the electrical power required.

Solution:

State 1: 165 kPa, x = 1, Table B.5.1: $h_1 = 389.2$ kJ/kg, $s_1 = 1.7354$ kJ/kg K

State 3: 1200 kPa, 46.31°C, x = 0, Table B.5.1: $h_3 = 266.13$ kJ/kg

C.V. Compressor

Energy Eq.: $w_C = h_2 - h_1$

Entropy Eq.: $s_2 = s_1 + s_{gen} = s_1$

State 2: 1.2 MPa , $s_2 = s_1 = 1.7354$ kJ/kg, $T_2 \approx 53.4^oC$, $h_2 = 430.67$ kJ/kg

$w_C = h_2 - h_1 = 430.67 - 389.2 = 41.47$ kJ/kg

Energy Eq. evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 389.2 - 266.13 = 123.07$ kJ/kg

COP Refrigerator: $$\beta = \frac{q_L}{w_C} = \frac{123.07}{41.47} = \mathbf{2.97}$$

Power: $\dot{W}_{IN} = \dot{Q}_L / \beta = 500$ W/ 2.97 = **168.3 W**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.102

Consider the previous problem and find the two rates of entropy generation in the process and where they occur.

Solution:

State 1: 165 kPa, x = 1, Table B.5.1: $h_1 = 389.2$ kJ/kg, $s_1 = 1.7354$ kJ/kg K

State 3: 1200 kPa, x = 0, Table B.5.1: $h_3 = 266.13$ kJ/kg, $s_3 = 1.2204$ kJ/kg K

Energy Eq. evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 389.2 - 266.13 = 123.07$ kJ/kg

Mass flow rate: $\dot{m} = \dot{Q}_L / q_L = 0.5 / 123.07 = 0.00406$ kg/s

C.V. Valve

Energy Eq.: $h_4 = h_3 = 266.13$ kJ/kg => $x_4 = (h_4 - h_f)/h_{fg}$

$$x_4 = \frac{266.13 - 180.19}{209.0} = 0.4112$$

$s_4 = s_f + x_4 s_{fg} = 0.9258 + x_4 \times 0.8096 = 1.2587$ kJ/kg K

Entropy Eq.: $s_{gen} = s_4 - s_3 = 1.2587 - 1.2204 = 0.0383$ kJ/kg K

$\dot{S}_{gen\ valve} = \dot{m} s_{gen} = 0.00406 \times 0.0383 \times 1000 =$ **0.155 W/K**

There is also entropy generation in the heat transfer process from the specimen at –10°C to the refrigerant $T_1 = -15°C = T_{sat}$ (165 kPa).

$$\dot{S}_{gen\ inside} = \dot{Q}_L \left[\frac{1}{T_{specimen}} - \frac{1}{T_L} \right] = 500 \left(\frac{1}{258.15} - \frac{1}{263.15} \right) =$$ **0.0368 W/K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.103

A refrigerator using R-134a is located in a 20°C room. Consider the cycle to be ideal, except that the compressor is neither adiabatic nor reversible. Saturated vapor at -20°C enters the compressor, and the R-134a exits the compressor at 50°C. The condenser temperature is 40°C. The mass flow rate of refrigerant around the cycle is 0.2 kg/s, and the coefficient of performance is measured and found to be 2.3. Find the power input to the compressor and the rate of entropy generation in the compressor process.

Solution:

Table B.5: $P_2 = P_3 = P_{sat\ 40C} = 1017$ kPa, $h_4 = h_3 = 256.54$ kJ/kg

$s_2 \approx 1.7472$ kJ/kg K, $h_2 \approx 430.87$ kJ/kg;

$s_1 = 1.7395$ kJ/kg K, $h_1 = 386.08$ kJ/kg

$\beta = q_L / w_C$ -> $w_C = q_L / \beta = (h_1 - h_4) / \beta = (386.08 - 256.54) / 2.3 = 56.32$

$$\dot{W}_C = \dot{m}\, w_C = \mathbf{11.26\ kW}$$

C.V. Compressor $h_1 + w_C + q = h_2$ ->

$q_{in} = h_2 - h_1 - w_C = 430.87 - 386.08 - 56.32 = -11.53$ kJ/kg i.e. a heat loss

$s_1 + \int dQ/T + s_{gen} = s_2$

$s_{gen} = s_2 - s_1 - q / T_o = 1.7472 - 1.7395 + (11.53 / 293.15) = 0.047$ kJ/kg K

$$\dot{S}_{gen} = \dot{m}\, s_{gen} = 0.2 \times 0.047 = \mathbf{0.0094\ kW / K}$$

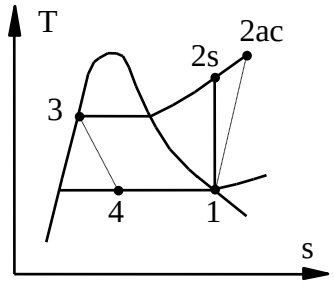
Ideal refrigeration cycle
with actual compressor

$T_{cond} = 40^oC$

$T_2 = 50^oC$

$T_{evap} = -20^oC = T_1$

Properties from Table B.5



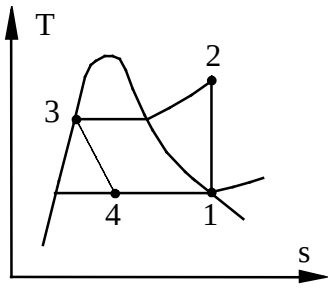
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.104

A small heat pump unit is used to heat water for a hot-water supply. Assume that the unit uses ammonia and operates on the ideal refrigeration cycle. The evaporator temperature is 15°C and the condenser temperature is 60°C. If the amount of hot water needed is 0.1 kg/s, determine the amount of energy saved by using the heat pump instead of directly heating the water from 15 to 60°C.

Solution:

Ideal ammonia heat pump



$T_1 = 15^oC, \quad T_3 = 60^oC$
From Table B.2.1

$h_1 = 1456.3$ kJ/kg, $\quad s_2 = s_1 = 5.1444$ kJ/kg K
$P_2 = P_3 = 2.614$ MPa, $\quad h_3 = 472.8$ kJ/kg

Entropy compressor: $s_2 = s_1 \quad => \quad T_2 = 111.6^oC, \quad h_2 = 1643$ kJ/kg

Energy eq. compressor: $w_C = h_2 - h_1 = 186.7$ kJ/kg

Energy condenser: $q_H = h_2 - h_3 = 1170.2$ kJ/kg

To heat 0.1 kg/s of water from 15^oC to 60^oC,

$$\dot{Q}_{H2O} = \dot{m}(\Delta h) = 0.1(251.11 - 62.98) = 18.81 \text{ kW}$$

Using the heat pump

$$\dot{W}_{IN} = \dot{Q}_{H2O}(w_C/q_H) = 18.81(186.7 / 1170.2) = 3.0 \text{ kW}$$

a saving of **15.8 kW**

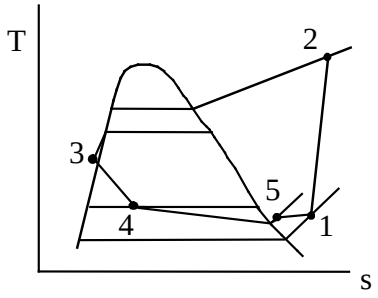
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.105

In an actual refrigeration cycle using R-134a as the working fluid, the refrigerant flow rate is 0.05 kg/s. Vapor enters the compressor at 150 kPa, -10°C (h_1 = 394.2 kJ/kg, s_1 = 1.739 kJ/kg-K), and leaves at 1.2 MPa, 75°C (h_2 = 454.2 kJ/kg, s_2 = 1.805 kJ/kg-K). The power input to the non-adiabatic compressor is measured and found be 2.4 kW. The refrigerant enters the expansion valve at 1.15 MPa, 40°C (h = 256.4 kJ/kg), and leaves the evaporator at 160 kPa, -15°C (h = 389.8 kJ/kg). Determine the entropy generation in the compression process, the refrigeration capacity and the coefficient of performance for this cycle.

Solution:

Actual refrigeration cycle



1: compressor inlet $T_1 = -10^oC$, $P_1 = 150$ kPa

2: compressor exit $T_2 = 75^oC$, $P_2 = 1.2$ MPa

3: Expansion valve inlet $T_3 = 40^oC$
$P_3 = 1.15$ MPa

5: evaporator exit $T_5 = -15^oC$, $P_5 = 160$ kPa

Table B.5 (CATT3) $h_1 = 394.2$ kJ/kg, $s_1 = 1.739$ kJ/kg-K,
$h_2 = 454.2$ kJ/kg, $s_2 = 1.805$ kJ/kg-K

CV Compressor: $h_1 + q_{COMP} + w_{COMP} = h_2$; $s_1 + \int dq/T + s_{gen} = s_2$

$w_{COMP} = \dot{W}_{COMP}/\dot{m} = 2.4/0.05 = 48.0$ kJ/kg

$q_{COMP} = h_2 - w_{COMP} - h_1 = 454.2 - 48.0 - 394.2 = 12$ kJ/kg

$s_{gen} = s_2 - s_1 - q / T_o = 1.805 - 1.739 - 12/298.15 =$ **0.0258 kJ/kg-K**

C.V. Evaporator

$q_L = h_5 - h_4 = 389.8 - 256.4 = 133.4$ kJ/kg

$\Rightarrow \dot{Q}_L = \dot{m} q_L = 0.05 \times 133.4 =$ **6.67 kW**

COP: $\beta = \dfrac{q_L}{w_{COMP}} = \dfrac{133.4}{48.0} =$ **2.78**

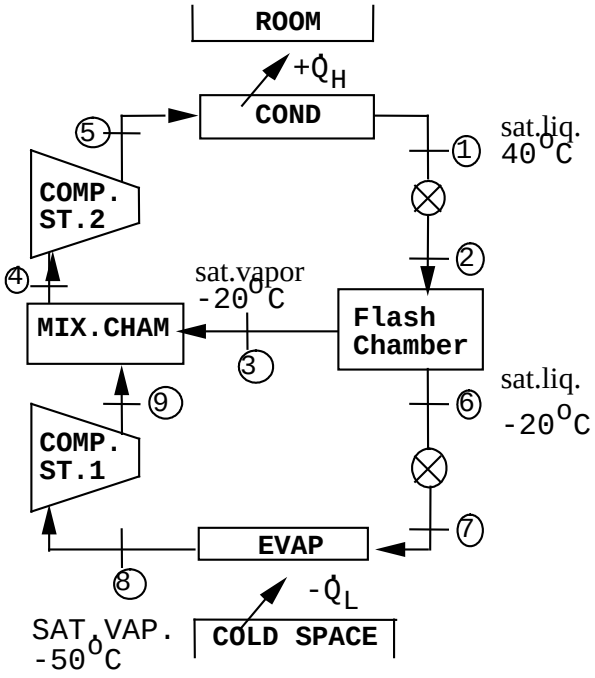
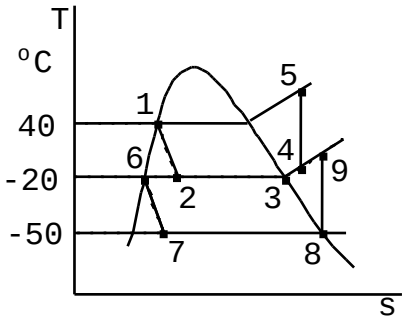
9.106

One means of improving the performance of a refrigeration system that operates over a wide temperature range is to use a two-stage compressor. Consider an ideal refrigeration system of this type that uses R-410A as the working fluid, as shown in Fig. 9.25. Saturated liquid leaves the condenser at 40°C and is throttled to -20° C. The liquid and vapor at this temperature are separated, and the liquid is throttled to the evaporator temperature, -50°C. Vapor leaving the evaporator is compressed to the saturation pressure corresponding to -20°C, after which it is mixed with the vapor leaving the flash chamber. It may be assumed that both the flash chamber and the mixing chamber are well insulated to prevent heat transfer from the ambient. Vapor leaving the mixing chamber is compressed in the second stage of the compressor to the saturation pressure corresponding to the condenser temperature, 40°C. Determine the COP of the system. Compare to the COP of a simple ideal refrigeration cycle operating over the same condenser and evaporator ranges as those of the two-stage compressor unit studied in this problem (T_2 = 90.7 °C, h_2 = 350.35 kJ/kg).





R-410A refrigerator with 2-stage compression

CV: expansion valve, upper loop

$h_2 = h_1 = 124.09 = 28.24 + x_2 \times 243.65$; $x_2 = 0.3934$

$m_3 = x_2 m_2 = x_2 m_1 = 0.3934$ kg (for m_1=1 kg)

$m_6 = m_1 - m_3 = 0.6066$ kg

CV: expansion valve, lower loop

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$h_7 = h_6 = 28.24 = -13.8 + x_7 \times 271.6, \quad x_7 = 0.15478$

$Q_L = m_6 (h_8 - h_7) = 0.6066 (257.80 – 28.24) = 139.25$ kJ

$q_L = Q_L / m_1 = 139.25$ kJ/kg-m_1

CV: 1st stage compressor

$s_8 = s_9 = 1.1568$ kJ/kg-K, $P_9 = P_{SAT\ -20\ ^oC} = 0.3996$ MPa

$\Rightarrow T_9 = 2.7\ ^oC, \quad h_9 = 292.82$ kJ/kg

CV: mixing chamber (assume constant pressure mixing)

Energy Eq.: $m_6h_9 + m_3h_3 = m_1h_4$

or $h_4 = 0.6066 \times 292.82 + 0.3934 \times 271.89 = 284.6$ kJ/kg

$h_4, P_4 \approx 400$ kPa $\Rightarrow T_4 = -6.3\ ^oC, \ s_4 = 1.1261$ kJ/kg K

CV: 2nd stage compressor $P_4 = 400$ kPa $= P_9 = P_3$

$P_5 = P_{sat\ 40^oC} = 2.4207$ MPa, $s_5 = s_4 \Rightarrow T_5 = 81.3^oC, h_5 = 339.42$ kJ/kg

CV: condenser

Energy Eq.: $q_H = h_5 - h_1 = 339.42 - 124.09 = 215.33$ kJ/kg

$\beta_{2\ stage} = q_L/(q_H - q_L) = 139.25/(215.33 – 139.25) =$ **1.83**

b) 1 stage compression

$h_3 = h_4 = 124.09$ kJ/kg

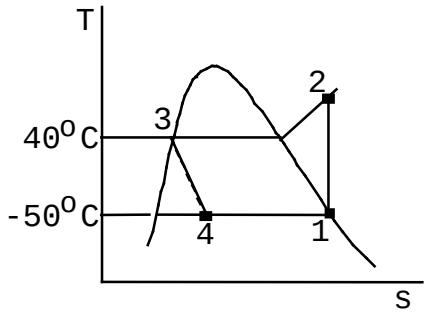
$h_1 = 257.80$ kJ/kg

$q_L = h_1 - h_4 = 133.7$ kJ/kg

$s_1 = s_2 = 1.1568$

$P_2 = 2.4207$ MPa

$\Rightarrow T_2 = 90.7\ ^oC, h_2 = 350.35$



$q_H = h_2 - h_3 = 350.35 - 124.09 = 226.26$ kJ/kg

$\beta_{1\ stage} = q_L/(q_H - q_L) = 133.7/(226.26 - 133.7) =$ **1.44**

9.109

A split evaporator is used to provide cooling of the refrigerator section and separate cooling of the freezer section as shown in Fig. P9.109. Assume constant pressure in the two evaporators. How does the COP = $(Q_{L1} + Q_{L2})/W$ compare to a refrigerator with a single evaporator at the lowest temperature?

Throttle processes: $h_4 = h_3$; $h_5 = h_6$

Refrigerator: $q_{L\,R} = h_5 - h_4$

freezer: $q_{L\,F} = h_1 - h_6$

Add the two heat transfers: $q_{L\,R} + q_{L\,F} = h_5 - h_4 + h_1 - h_6 = h_1 - h_4$

which is the **same** as for the standard cycle expanding to the lowest pressure.

$$COP_{split} = COP_{std} = (h_1 - h_4) / (h_2 - h_1)$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.110

A refrigerator using R-410A is powered by a small natural gas fired heat engine with a thermal efficiency of 25%, as shown in Fig. P9.110. The R-410A condenses at 40°C and it evaporates at –20°C and the cycle is standard. Find the two specific heat transfers in the refrigeration cycle. What is the overall coefficient of performance as Q_L/Q_1?

Solution:

Evaporator: Inlet State is saturated liq-vap with $h_4 = h_3 = 124.09$ kJ/kg

The exit state is saturated vapor with $h_1 = 271.89$ kJ/kg

$q_L = h_1 - h_4 = h_1 - h_3 =$ **147.8 kJ/kg**

Compressor: Inlet State 1 and Exit State 2 about 2.42 MPa

$w_C = h_2 - h_1$; $s_2 = s_1 = 1.0779$ kJ/kgK

2: $T_2 \approx 70°C$ $h_2 = 322.6$ kJ/kg

$w_C = h_2 - h_1 = 50.71$ kJ/kg

Condenser: Brings it to saturated liquid at state 3

$q_H = h_2 - h_3 = 322.6 - 124.09 =$ **198.5 kJ/kg**

Overall Refrigerator:

$$\beta = q_L / w_C = 147.8 / 50.71 = 2.915$$

Heat Engine:

$$\dot{W}_{HE} = \eta_{HE}\dot{Q}_1 = \dot{W}_C = \dot{Q}_L / \beta$$

$$\dot{Q}_L / \dot{Q}_1 = \eta\beta = 0.25 \times 2.915 =$$ **0.729**

Ideal refrigeration cycle

$T_{cond} = 40^oC = T_3$

$T_{evap} = -20^oC = T_1$

Properties from Table B.4

Ammonia absorption cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.111

Notice the configuration in Fig.9.29 has the left hand side column of devices substitute for a compressor in the standard cycle. What is an expression for the equivalent work output from the left hand side devices, assuming they are reversible and the high and low temperatures are constant, as a function of the pump work W and the two temperatures.

The left hand side devices works like a combination of a heat engine with some additional shaft work input. We can analyze this with a control volume around all the devices that substitute for the compressor in the standard cycle.

C.V. Pump, absorber, heat exchanger and generator.
This C.V. has an inlet flow at state 1 and exit flow at state 2 with numbers as in the standard cycle.

Energy Eq.: $0 = h_1 + w + q'_H - q'_L - h_2$ all per mass flow at 1 and 2.

Entropy Eq.: $0 = s_1 + \frac{q'_H}{T_{H'}} - \frac{q'_L}{T_{L'}} - s_2 + 0$

Now solve for q'_L from the entropy equation and substitute into the energy equation

$$q'_L = T_{L'} (s_1 - s_2) + (T_{L'} / T_{H'})\, q'_H$$

$$w + [1 - \frac{T_{L'}}{T_{H'}}]\, q'_H = (h_2 - h_1) - T_{L'} (s_2 - s_1)$$

The high T heat transfer acts as if it was delivered to a Carnot heat engine and the Carnot heat engine work output was added to the shaft work w. That sum gives the increase in exergy from state 1 to state 2. Notice in the standard cycle, $s_2 = s_1$, and the last term is zero.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.112

As explained in the previous Problem the ammonia absorption cycle is very similar to the set-up sketched in Problem 9.110. Assume the heat engine has an efficiency of 30% and the COP of the refrigeration cycle is 3.0 what is then the ratio of the cooling to the heating heat transfer Q_L/Q_1?

Heat Engine: $W = \eta Q_1 = 0.3\ Q_1$

Refrigerator.: $\beta = Q_L / W \quad \Rightarrow \quad Q_L = \beta\ W = \beta\ \eta Q_1$

So now

$$Q_L/Q_1 = \beta\ \eta = 3 \times 0.3 = \mathbf{0.9}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.113

Give an estimate for the overall COP' of an ammonia absorption cycle used as a chiller to cool water to 5°C in an 25°C ambient when the small pump work is neglected. A heat source is available at 100°C. Find also the efficiency of the heat engine part and the COP of the refrigeration cycle part.

The heat engine operates between the 100°C source and the 25°C ambient so

$$\eta_{HE} = 1 - T_o/T_s = 1 - \frac{298.15}{373.15} = \mathbf{0.20}$$

To estimate the COP of the basic ammonia cycle consider the high/low temperatures to be as $T_2 = 25°C$ and $T_4 = 5°C$. From B.2.1 we get

$P_2 = P_{sat\ 25C} = 1003$ kPa, $h_3 = h_2 = 298.25$ kJ/kg, $h_4 = 1447.3$ kJ/kg,

Assume $T_1 = 100°C$, $P_1 = P_2$, $h_1 = 1664.3$ kJ/kg

$$COP = q_L / w_C = (h_4 - h_2)/(h_1 - h_4) = \frac{1447.3 - 298.25}{1664.3 - 1447.3} = \mathbf{5.3}$$

Neglecting the small pump work we get

$$COP' = COP \times \eta_{HE} = 5.3 \times 0.2 = \mathbf{1.06}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.114

Consider a small ammonia absorption refrigeration cycle that is powered by solar energy and is to be used as an air conditioner. Saturated vapor ammonia leaves the generator at 50°C, and saturated vapor leaves the evaporator at 10°C. If 3000 kJ of heat is required in the generator (solar collector) per kilogram of ammonia vapor generated, determine the overall performance of this system.

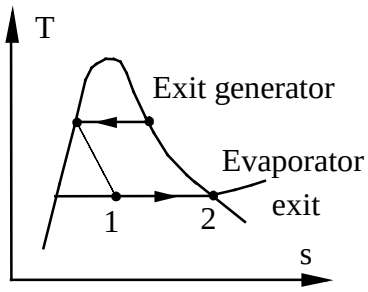
Solution;

NH_3 absorption cycle:

sat. vapor at 50^oC exits the generator

sat. vapor at 10^oC exits the evaporator

$q_H = q_{GEN} = 3000$ kJ/kg NH_3 out of gen.



C.V. Evaporator

$$q_L = h_2 - h_1 = h_{g\ 10^oC} - h_{f\ 50^oC} = 1452.2 - 421.6 = 1030.6 \text{ kJ/kg}$$

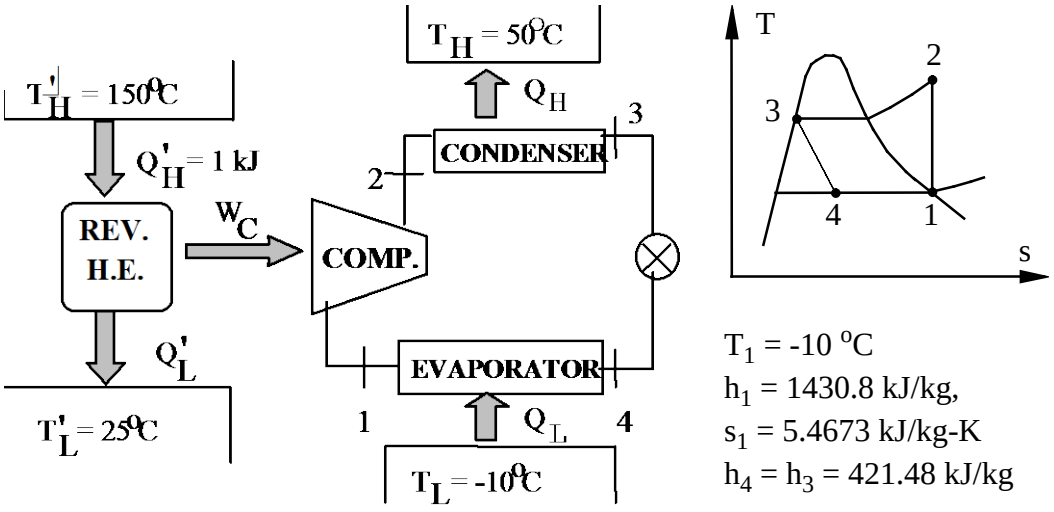
COP $\Rightarrow$ $q_L/q_H = 1030.6/3000 =$ **0.34**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.115

The performance of an ammonia absorption cycle refrigerator is to be compared with that of a similar vapor-compression system. Consider an absorption system having an evaporator temperature of −10°C and a condenser temperature of 50°C. The generator temperature in this system is 150°C. In this cycle 0.42 kJ is transferred to the ammonia in the evaporator for each kilojoule transferred from the high-temperature source to the ammonia solution in the generator. To make the comparison, assume that a reservoir is available at 150°C, and that heat is transferred from this reservoir to a reversible engine that rejects heat to the surroundings at 25°C. This work is then used to drive an ideal vapor-compression system with ammonia as the refrigerant. Compare the amount of refrigeration that can be achieved per kilojoule from the high-temperature source with the 0.42 kJ that can be achieved in the absorption system.

Solution:



$T_1 = -10\ ^{o}C$
$h_1 = 1430.8$ kJ/kg,
$s_1 = 5.4673$ kJ/kg-K
$h_4 = h_3 = 421.48$ kJ/kg

For the rev. heat engine: $\eta_{TH} = 1 - T_L'/T_H' = 1 - \dfrac{298.2}{423.2} = 0.295$

$$\Rightarrow \quad W_C = \eta_{TH} Q_H' = 0.295 \text{ kJ}$$

For the NH_3 refrig. cycle: $P_2 = P_3 = 2033$ kPa , Use 2000 kPa Table

$s_2 = s_1 = 5.4673$ kJ/kg-K => $T_2 \approx 135°C$, $h_2 \approx 1724$ kJ/kg

$w_C = h_2 - h_1 = 1724 - 1430.8 = 293.2$ kJ/kg

$q_L = h_1 - h_4 = 1430.8 - 421.48 = 1009.3$ kJ/kg

$\beta = q_L/w_C = 1009.3 / 293.2 = 3.44$

$\Rightarrow Q_L = \beta w_C = 3.44 \times 0.295 =$ **1.015 kJ**

This is based on the assumption of an ideal heat engine & refrigeration cycle.

Exergy Concepts

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.116

If we neglect the external irreversibilities due to the heat transfers over finite temperature differences in a power plant how would you define its second law efficiency?

The first law efficiency is a conversion efficiency as

$$\eta_I = \frac{w_{net}}{q_H} = \frac{w_{net}}{h_3 - h_2}$$

The second law efficiency is the same ratio but expressed in exergy

$$\eta_{II} = \frac{\text{output}}{\text{source}} = \frac{w_{net}}{\varphi_H} = \frac{w_{net}}{\varphi_3 - \varphi_2} \quad \text{or} \quad = \frac{w_{net}}{\varphi_H - \varphi_L}$$

The last expression must be used if the heat rejection at the low T is assigned any exergy value (normally not).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.117

Find the exergy of the water at all four states in the Rankine cycle described in Problem 9.16. Assume that the high-temperature source is 500°C and the low-temperature reservoir is at 25°C. Determine the flow of exergy in or out of the reservoirs per kilogram of steam flowing in the cycle. What is the overall cycle second law efficiency?

Solution (States and properties are from solution to problem 9.16):

Reference State: 100 kPa, 25°C, $s_o = 0.3673$ kJ/kg K, $h_o = 104.87$ kJ/kg

$\psi_1 = h_1 - h_o - T_o(s_1 - s_o)$

$= 251.11 - 104.87 - 298.15(0.8311 - 0.3673) = 7.958$ kJ/kg

$\psi_2 = 254.14 - 104.87 - 298.15(0.8311 - 0.3673) = \psi_1 + 3.03 = 10.99$ kJ/kg

$\psi_3 = 3344 - 104.87 - 298.15(7.0833 - 0.3673) = 1236.75$ kJ/kg

$\psi_4 = \psi_3 - w_{T,s} = 1236.75 - 1009.6 = 227.1$ kJ/kg

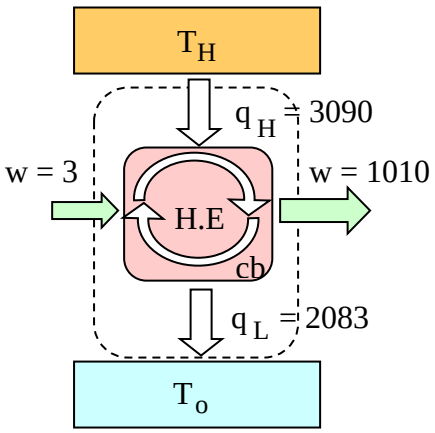
$\Delta\psi_H = (1 - T_o/T_H)q_H = 0.6144 \times 3089.86 = 1898.4$ kJ/kg

$\Delta\psi_L = (1 - T_o/T_o)q_C = 0$ kJ/kg

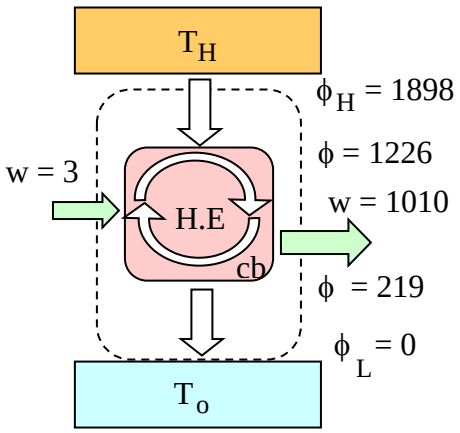
$\eta_{II} = w_{NET}/\Delta\psi_H = (1009.6 - 3.03)/1898.4 =$ **0.53**

Notice— $T_H > T_3$, $T_L < T_4 = T_1$ so cycle is externally irreversible. Both q_H and q_C are over finite ΔT.

Energy Transfers (kJ/kg):



Exergy Transfers (kJ/kg):

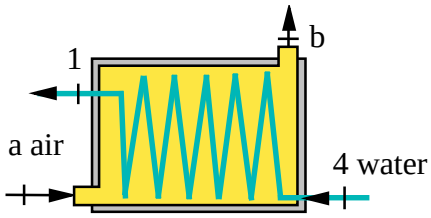


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.118

A condenser is maintained at 60°C by cooling it with atmospheric air coming in at 20°C and leaving at 35 °C. The condenser must reject 25 MW from the water to the air. Find the flow rate of air and the second law efficiency of the heat exchanger.

C.V. Condenser, a dual steady flow 1 inlet and 1 exit for air and water each. The two flows exchange energy with no heat transfer to/from the outside.



Energy Eq.: $0 = \dot{m}_{H2O}\,(h_4 - h_1) + \dot{m}_{air}\,(h_a - h_b)$

$$\dot{m}_{H2O}\,(h_4 - h_1) = \dot{Q} = \dot{m}_{air}\,(h_b - h_a) = \dot{m}_{air}\,C_p\,(T_b - T_a)$$

$$\dot{m}_{air} = \dot{Q} / C_p\,(T_b - T_a) = \frac{25\ 000\ \text{kW}}{1.004 \times 15\ \text{kJ/kg}} = \mathbf{1660\ kg/s}$$

Since the water is at constant T the change in entropy equals $\dot{Q}/T$ and the exergy terms for the water and air becomes

$$\Delta\dot{\Phi}_{water} = \dot{Q}\,(1 - \frac{T_0}{T_{H2O}}) = 25\ \text{MW}\ (\ 1 - \frac{293.15}{333.15}) = 3001.6\ \text{kW}$$

$$s_b - s_a = C_p\ \ln(\ T_b/T_a\ ) = 1.004\ \ln\ (308.15/293.15) = 0.0501\ \text{kJ/kgK}$$

$$\Delta\dot{\Phi}_{air} = \dot{m}_{air}\,[h_b - h_a - T_0\,(s_b - s_a)] = \dot{Q} - \dot{m}_{air} T_0\,(s_b - s_a)$$

$$= 25\ 000 - 1660 \times 293.15 \times 0.0501 = 619.89\ \text{kW}$$

$$\eta_{II} = \Delta\dot{\Phi}_{air} / \Delta\dot{\Phi}_{water} = \frac{619.89}{3001.6} = \mathbf{0.2065}$$

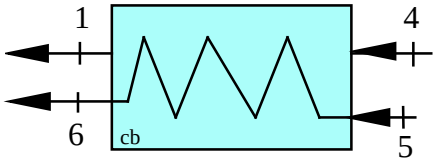
Comment: We used $T_0 = 20°C = 293.15$ K, since the air comes in at that T, in order not to straddle the T_0 with the air temperatures. Recall exergy is positive for T's higher and lower than T_0.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.119

Find the flows and fluxes of exergy in the condenser of Problem 9.29. Use those to determine the second law efficiency, T_o = 15°C.

For this case we select T_o = 15°C = 288 K, the ocean water temperature.



The states properties from Tables B.1.1 and B.1.3

1: 45°C, x = 0: h_1 = 188.42 kJ/kg,

3: 3.0 MPa, 600°C: s_3 = 7.5084 kJ/kg K

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$

$$s_4 = s_3 = 7.5084 = 0.6386 + x_4\,(7.5261) \quad \Rightarrow \quad x_4 = 0.9128$$

$$\Rightarrow\ h_4 = 188.42 + 0.9128\,(2394.77) = 2374.4 \text{ kJ/kg}$$

C.V. Condenser : $q_L = h_4 - h_1 = 2374.4 - 188.42 = 2186$ kJ/kg

$$\dot{Q}_L = \dot{m} q_L = 25 \times 2186 = 54.65 \text{ MW} = \dot{m}_{ocean}\, C_p\, \Delta T$$

$$\dot{m}_{ocean} = \dot{Q}_L / C_p\, \Delta T = 54\,650 / (4.18 \times 3) = 4358 \text{ kg/s}$$

The net drop in exergy of the water is

$$\dot{\Phi}_{water} = \dot{m}_{water}\,[h_4 - h_1 - T_o(s_4 - s_1)]$$

$$= 25\,[\,2374.4 - 188.4 - 285\,(7.5084 - 0.6386)]$$

$$= 54\,650 - 48\,947 = \mathbf{5703\ kW}$$

The net gain in exergy of the ocean water is

$$\dot{\Phi}_{ocean} = \dot{m}_{ocean}[h_6 - h_5 - T_o(s_6 - s_5)]$$

$$= \dot{m}_{ocean}\left[C_p(T_6 - T_5) - T_o C_p \ln\left(\frac{T_6}{T_5}\right)\right]$$

$$= 4358\left[\,4.18(15 - 12) - 285 \times 4.18 \ln\frac{273 + 15}{273 + 12}\right]$$

$$= 54\,650 - 54\,364 = \mathbf{286\ kW}$$

The second law efficiency is

$$\eta_{II} = \dot{\Phi}_{ocean} / \dot{\Phi}_{water} = \frac{286}{5703} = \mathbf{0.05}$$

In reality all the exergy in the ocean water is destroyed as the 15°C water mixes with the ocean water at 12°C after it flows back out into the ocean and the efficiency does not have any significance. Notice the small rate of exergy relative to the large rates of energy being transferred.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.120

Find the second law efficiency for the open FWH in Problem 9.40

The setup follows Fig.9.12

State enthalpies [kJ/kg]: $h_2 = 419.02$, $h_6 = 2827.86$, $h_3 = 762.79$ (x = 0 at 1 MPa)

State entropies [kJ/kgK]: $s_2 = 1.3068$, $s_6 = 6.6939$, $s_3 = 2.1386$

Analyze the FWH which leads to Eq.9.5:

$$y = \dot{m}_6 / \dot{m}_5 \quad \text{the extraction fraction} \quad (\dot{m}_5 = \dot{m}_3)$$

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{762.79 - 419.02}{2827.86 - 419.02} = 0.1427$$

The second law efficiency for this FWH can be done similar to a co-flowing heat exchanger. The extraction flow, fraction y of total flow, provides the source of exergy as it goes from state 6 to state 3. The feedwater flow, with fraction (1 – y), increase its exergy from state 2 to state 3.

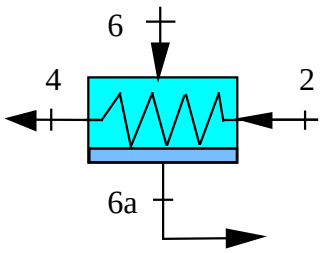
$$\begin{aligned}
\psi_3 - \psi_2 &= h_3 - h_2 - T_o(s_3 - s_2) \\
&= 762.79 - 419.02 - 298.15(2.1386 - 1.3068) \\
&= 95.769 \text{ kJ/kg} \\
\psi_6 - \psi_3 &= h_6 - h_3 - T_o(s_6 - s_3) \\
&= 2827.86 - 762.79 - 298.15(6.6939 - 2.1386) \\
&= 706.907 \text{ kJ/kg}
\end{aligned}$$

$$\eta_{II} = \frac{(1 - y)(\psi_3 - \psi_2)}{y(\psi_6 - \psi_3)} = \frac{0.8573 \times 95.769}{0.1427 \times 706.907} = \mathbf{0.814}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.121

Find the second law efficiency for the closed FWH in Problem 9.51



From table B.1		h kJ/kg	s kJ/kg-K
B.1.4:	100°C, 20 MPa	h_2 = 434.04	1.2917
B.1.4:	200°C, 20 MPa	h_4 = 860.47	2.3031
B.1.3:	4 MPa, 275°C	h_6 = 2880.39	6.2145
B.1.2:	4 MPa, sat. liq.	h_{6a} = 1087.29	2.7963

C.V. Feedwater Heater

Energy Eq.: $\dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_2 h_4 + \dot{m}_6 h_{6a}$

Since all four states are known we can solve for the extraction flow rate

$$\dot{m}_6 = \dot{m}_2 \frac{h_2 - h_4}{h_{6a} - h_6} = 20 \frac{434.04 - 860.47}{1087.29 - 2880.39} \text{ kg/s} = 4.756 \text{ kg/s}$$

The feedwater from state 2 to state 4 gains exergy from the extraction flow which provides the source as it goes from state 6 to state 6a.

$$\psi_4 - \psi_2 = h_4 - h_2 - T_o(s_4 - s_2)$$
$$= 860.47 - 434.04 - 298.15(2.3031 - 1.2917)$$
$$= 124.881 \text{ kJ/kg}$$
$$\psi_6 - \psi_{6a} = h_6 - h_{6a} - T_o(s_6 - s_{6a})$$
$$= 2880.39 - 1087.29 - 298.15(6.2145 - 2.7963)$$
$$= 773.964 \text{ kJ/kg}$$

$$\eta_{II} = \frac{\dot{m}_2 (\psi_4 - \psi_2)}{\dot{m}_6 (\psi_6 - \psi_{6a})} = \frac{20 \times 124.881}{4.756 \times 773.964} = \mathbf{0.679}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.122

For problem 9.58 consider the boiler/super-heater. Find the exergy destruction in this setup and the second law efficiency for the boiler-source set-up.

A Rankine cycle feeds 5 kg/s ammonia at 2 MPa, 140°C to the turbine, which has an extraction point at 800 kPa. The condenser is at -20°C and a closed feed water heater has an exit state (3) at the temperature of the condensing extraction flow and it has a drip pump. The source for the boiler is at constant 180°C. Find the extraction flow rate and state 4 into the boiler.

The boiler has flow in at state 4 and out at state 5 with the source providing a q at 180°C.

Assume state 4 is saturated liquid at T_4 so $h_4 = h_{f\,4}$ => $T_4 = 17.92^oC$

State 4: $h_4 = 264.4$ kJ/kg $= h_{f\,4}$, $s_4 = s_{f\,4} = 1.00705$ kJ/kgK

State 5: $h_5 = 1738.2$ kJ/kg, $s_5 = 5.5022$ kJ/kg K

Energy Eq. $q_H = h_5 - h_4 = 1738.2 - 264.4 = 1473.8$ kJ/kg

Entropy Eq. $s_4 + q_H/T_H + s_{gen} = s_5$ => $s_{gen} = s_5 - s_4 - q_H/T_H$

$$\dot{S}_{gen} = \dot{m} s_{gen} = 5\,[5.5022 - 1.00705 - \frac{1473.8}{180 + 273.15}]$$

$$= 5 \times 1.2428 = \mathbf{6.21\ kW/K}$$

The flow increase in exergy is:

$$\psi_5 - \psi_4 = h_5 - h_4 - T_o\,(s_5 - s_4) = 1473.8 - 298.15\,(5.5022 - 1.00705)$$

$$= 133.57\ \text{kJ/kg}$$

The exergy provided by the source is:

$$\phi_H = (1 - T_o/T_H)\, q_H = (1 - \frac{298.15}{180 + 273.15})\, 1473.8 = 504.1\ \text{kJ/kg}$$

Second law efficiency is

$$\eta_{II} = \frac{\text{gain in exergy}}{\text{source exergy input}} = \frac{133.57}{504.1} = \mathbf{0.265}$$

$$(= 1 - T_o s_{gen}/\phi_H = 1 - 298.15 \times 1.2428 / 504.1\ )$$

9.123

The power plant using ammonia in Problem 9.71 has a flow of liquid water at 120°C, 300 kPa as a heat source, the water leaves the heat exchanger at 90°C. Find the second law efficiency of this heat exchanger.

C.V. The liquid water source - ammonia boiler heat exchanger.

$\Delta h_{liq} = 503.69 - 376.9 = 126.79$ kJ/kg (sat. liquid at 120°C and 90°C)

$\Delta s_{liq} = 1.5275 - 1.1924 = 0.3351$ kJ/kgK

The energy equation establishes the ratio of the mass flow rates

$$\dot{Q}_H = \dot{m}_{water}\, \Delta h_{liq} = \dot{m}_{NH3}\, q_H$$

$$\Rightarrow \quad \dot{m}_{water} / \dot{m}_{NH3} = q_H / \Delta h_{liq} = 1442/126.79 = 11.373$$

Now the second law efficiency is the ratio of exergy pick-up over exergy source

$$\eta_{II} = \frac{\dot{m}_{NH3}\, \Delta\psi}{\dot{m}_{water}\, \Delta\psi} = \frac{\dot{m}_{NH3}\, [q_H - T_o(s_5 - s_3)]}{\dot{m}_{water}\, (\Delta h_{liq} - T_o \Delta s_{liq})}$$

From the power plant cycle we have state 3:

State 3: $x_3 = 0$, $h_3 = 171.65$ kJ/kg, $s_3 = 0.6793$ kJ/kgK, $v_3 = 0.00156$ m^3/kg

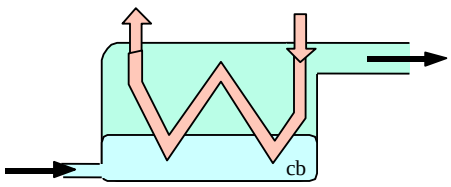
State 5: $h_5 = 1614.6$ kJ/kg, $s_5 = 5.4971$ kJ/kg K

C.V Pump P2: $w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.00156(1000 - 400) = 0.936$ kJ/kg

$$q_H = h_5 - h_4 = 1614.6 - (171.65 + 0.936) = 1442 \text{ kJ/kg}$$

$$s_5 - s_3 = 5.4971 - 0.6793 = 4.81775 \text{ kJ/kgK}$$

$$\eta_{II} = \frac{1}{11.373} \frac{1442 - 253.15 \times 4.81775}{126.79 - 253.15 \times 0.3351} = \mathbf{0.466}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.124

A concentrated solar power plant receives the energy from molten salt coming in at 560°C and leaving at 300°C in counterflow heat exchanger where the water comes in at 3 MPa, 60°C and leaves at 450°C, 3 MPa. The molten salt has 5 kg/s flow with $C_{P\ salt}$ = 1.5 kJ/kg-K. What is the possible water flow rate and the rate of energy transfer. Find the second law efficiency of this heat exchanger.

Continuity Eqs.: Each line has a constant flow rate through it.

Energy Eq.4.10: $0 = \dot{m}_{H_2O}(h_1 - h_2) + \dot{m}_{salt}(h_3 - h_4)$

Entropy Eq.7.7: $0 = \dot{m}_{H_2O}(s_1 - s_2) + \dot{m}_{salt}(s_3 - s_4) + \dot{S}_{gen}$

Process: Each line has a constant pressure.

Table B.1: h_1 = 253.61 kJ/kg, h_2 = 3344 kJ/kg, s_1 = 0.8295, s_2 = 7.0833 kJ/kg-K

$$\psi_2 - \psi_1 = [h_2 - h_1 - T_0(s_2 - s_1)]$$

$$= [3344 - 253.61 - 298.15\ (7.0833 - 0.8295)] = 1225.82\ \text{kJ/kg}$$

For the salt we get

$$h_3 - h_4 = C_{P\ salt}(T_3 - T_4) = 1.5\ (560 - 300) = 390\ \text{kJ/kg}$$

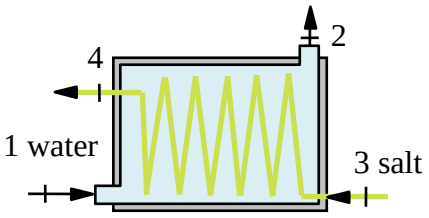
$$s_3 - s_4 = C_{P\ salt} \ln(T_3/T_4) = 1.5 \ln(833.15/573.15) = 0.561\ \text{kJ/kgK}$$

$$\psi_3 - \psi_4 = [h_3 - h_4 - T_0(s_3 - s_4)] = 390 - 298.15 \times 0.561 = 222.74\ \text{kJ/kgK}$$

$$\dot{m}_{H_2O} = \dot{m}_{salt}\frac{h_3 - h_4}{h_2 - h_1} = \frac{390}{3344 - 253.61} = 0.631\ \text{kg/s}$$

$$\eta_{II} = \frac{\dot{m}_{H2O}(\psi_2 - \psi_1)}{\dot{m}_{salt}(\psi_3 - \psi_4)} = \frac{0.631 \times 1225.82}{5 \times 222.74} = \mathbf{0.69}$$

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for salt and water each. The two flows exchange energy with no heat transfer to/from the outside.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.125

What is the second law efficiency of the heat pump in Problem 9.92?

A heat pump for heat upgrade uses ammonia with a low temperature of 25°C and a high pressure of 5000 kPa. If it receives 1 MW of shaft work what is the rate of heat transfer at the high temperature?

State 1: $h_1 = 1463.5$ kJ/kg, $s_1 = 5.0293$ kJ/kgK

State 3: $h_3 = h_f = 631.9$ kJ/kg, $s_3 = 2.1100$ kJ/kg-K

Entropy compressor: $s_2 = s_1$ => $T_2 = 156^oC$, $h_2 = 1709.1$ kJ/kg

Energy eq. compressor: $w_C = h_2 - h_1 = 245.6$ kJ/kg

Energy condenser: $q_H = h_2 - h_3 = 1077.2$ kJ/kg

Exergy output: $\Delta\psi_H = \psi_2 - \psi_3 = h_2 - h_3 - T_0(s_2 - s_3)$

$= 1077.2 - 298\ (5.0293 - 2.1100)$

$= 207.25$ kJ/kg

$$\eta_{II} = \frac{\text{output}}{\text{source}} = \frac{\Delta\psi_H}{w_{C\ ac}} = \frac{207.25}{245.6} = \mathbf{0.844}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.126

Steam is supplied in a line at 3 MPa, 700°C. A turbine with an isentropic efficiency of 85% is connected to the line by a valve and it exhausts to the atmosphere at 100 kPa. If the steam is throttled down to 2 MPa before entering the turbine find the actual turbine specific work. Find the change in exergy through the valve and the second law efficiency of the turbine.

Take C.V. as valve and a C.V. as the turbine.

Valve: $h_2 = h_1 = 3911.7$ kJ/kg, $s_2 > s_1 = 7.7571$ kJ/kg K,

$h_2, P_2 \Rightarrow s_2 = 7.9425$ kJ/kg K

$\psi_1 - \psi_2 = h_1 - h_2 - T_0(s_1 - s_2) = 0 - 298.15(7.7571 - 7.9425) =$ **55.3 kJ/kg**

So some potential work is lost in the throttling process.

Ideal turbine: $s_3 = s_2 \Rightarrow h_{3s} = 2929.13$ kJ/kg $\quad w_{T,s} = 982.57$ kJ/kg

$w_{T,ac} = h_2 - h_{3ac} = \eta w_{T,s} =$ **835.2 kJ/kg**

$h_{3ac} = 3911.7 - 835.2 = 3076.5 \Rightarrow s_{3ac} = 8.219$ kJ/kg K

$w^{rev} = \psi_2 - \psi_{3ac} = h_2 - h_{3ac} - T_0(s_2 - s_{3ac}) = 835.2 - 298.15(7.9425 - 8.219)$

$= 917.63$ kJ/kg $\Rightarrow$

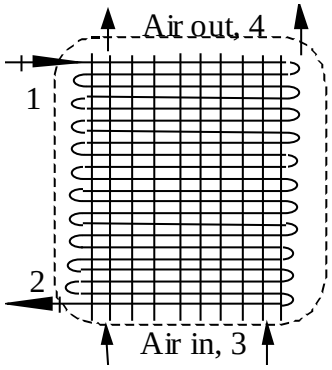
$\eta_{II} = w_{T,ac} / w^{rev} = 835.2/917.63 =$ **0.91**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.127

The condenser in a refrigerator receives R-134a at 700 kPa, 50°C and it exits as saturated liquid at 25°C. The flowrate is 0.1 kg/s and the condenser has air flowing in at ambient 15°C and leaving at 35°C. Find the minimum flow rate of air and the heat exchanger second-law efficiency.

C.V. Total heat exchanger.
Energy Eq.6.10



$$\dot{m}_1 h_1 + \dot{m}_a h_3 = \dot{m}_1 h_2 + \dot{m}_a h_4$$

$$\Rightarrow \quad \dot{m}_a = \dot{m}_1 \times \frac{h_1 - h_2}{h_4 - h_3}$$

$$= 0.1 \times \frac{436.89 - 234.59}{1.004(35 - 15)} = \mathbf{1.007\ kg/s}$$

Availability from Eq.8.24

$$\psi_1 - \psi_2 = h_1 - h_2 - T_0(s_1 - s_2) = 436.89 - 234.59$$

$$- 288.15(1.7919 - 1.1201) = 8.7208 \text{ kJ/kg}$$

$$\psi_4 - \psi_3 = h_4 - h_3 - T_0(s_4 - s_3)$$

$$= 1.004(35 - 15) - 288.15 \times 1.004 \times \ln \frac{308.15}{288.15} = +0.666 \text{ kJ/kg}$$

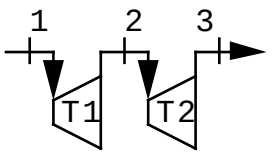
Efficiency from Eq.8.30

$$\eta_{II} = \frac{\dot{m}_a (\psi_4 - \psi_3)}{\dot{m}_1 (\psi_1 - \psi_2)} = \frac{1.007 \times 0.666}{0.1 \times 8.7208} = \mathbf{0.77}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.128

A flow of steam at 10 MPa, 550°C goes through a two-stage turbine. The pressure between the stages is 2 MPa and the second stage has an exit at 50 kPa. Assume both stages have an isentropic efficiency of 85%. Find the second law efficiencies for both stages of the turbine.



CV: T1, $h_1 = 3500.9$ kJ/kg, $s_1 = 6.7561$ kJ/kg K

Isentropic $s_{2s} = s_1 \Rightarrow h_{2s} = 3017.9$ kJ/kg

$w_{T1,s} = h_1 - h_{2s} = 483$ kJ/kg

Actual T1: $w_{T1,ac} = \eta_{T1}\, w_{T1,s} = 410.55 = h_1 - h_{2ac}$

$h_{2ac} = h_1 - w_{T1,ac} = 3090.35$ kJ/kg, $s_{2ac} = 6.8782$ kJ/kg K

CV: T2, $s_{3s} = s_{2ac} = 6.8782 \Rightarrow x_{3s} = (6.8782\text{-}1.091)/6.5029 = 0.8899$,

$h_{3s} = 340.47 + 0.8899 \times 2305.4 = 2392.2$ kJ/kg

$w_{T2,s} = h_{2ac} - h_{3s} = 698.15 \Rightarrow w_{T2,ac} = \eta_{T2}\, w_{T2,s} = 593.4$ kJ/kg

$\Rightarrow h_{3ac} = 2496.9$, $x_{3ac} = (2496.9 - 340.47)/2305.4 = 0.9354$,

$s_{3ac} = 1.091 + 0.9354 \times 6.5029 = 7.1736$ kJ/kg K

Actual T1: $i_{T1,ac} = T_0(s_{2ac}\text{-}s_1) = 298.15(6.8782 - 6.7561) = 36.4$ kJ/kg

$\Rightarrow w^R_{T1} = w_{T1,ac} + i = 447$ kJ/kg, $\eta_{II} = w_{T1,ac}/w^R_{T1} =$ **0.918**

Actual T2: $i_{T2,ac} = T_0(s_{3ac}\text{-}s_{2ac}) = 298.15(7.1736 - 6.8782) = 88.07$ kJ/kg

$\Rightarrow w^R_{T2} = w_{T2,ac} + i_{T2,ac} = 681.5$, $\eta_{II} = w_{T2,ac}/w^R_{T2} =$ **0.871**

9.129

A new air-conditioner using R-410A is used in heat pump mode. The high pressure is 2000 kPa and the low pressure is 400 kPa. It warms a house at 20°C driven by an electric power input of 2 kW in an ambient at -5°C. Find the destruction of exergy 4 places: 1) inside the heat pump, 2) in the high T heat exchanger, 3) in the low T heat exchanger, and 4) in the house walls/windows etc. that separates the inside from the outside of the house.

Exit evaporator x = 1, 400 kPa from B.4.2: $h_1 = 271.9$, $s_1 = 1.0779$ kJ/kgK

Exit condenser x = 0, 2 MPa from B.4.1: $h_3 = 110.21$ kJ/kg, $s_3 = 0.40378$ kJ/kgK

Exit valve: $h_3 = h_4 = 28.24 + x_4\ 243.66 \Rightarrow x_4 = 0.33638$, $s_4 = 0.43917$

Compressor: $s_2 = s_1$ & P_2 from B.4.2 $\Rightarrow$ $h_2 \approx 317.43$ kJ/kg

Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 271.9 - 110.21 = 161.69$ kJ/kg

Condenser: $q_H = h_2 - h_3 = 317.43 - 110.21 = 207.22$ kJ/kg

Compressor: $w_c = h_2 - h_1 = 317.43 - 271.9 = 45.53$ kJ/kg,

$\dot{m} = \dot{W}/ w_c = 2$ kW/45.53 kJ/kg = 0.04393 kg/s

COP: $\beta = q_H/w_c = 207.22/45.53 = 4.55$

Heat transfers: $\dot{Q}_H = \beta \dot{W} = 4.55 \times 2 = 9.1$ kW, $\dot{Q}_L = 9.1 - 2 = 7.1$ kW

CV: The A/C unit, entropy only made in valve.

$$\dot{\Phi}_{destr.\ HP} = T_0 \dot{S}_{gen} = \dot{m}\ T_0\ (s_4 - s_3)$$

$$= 0.04393 \text{ kg/s} \times 298.15 \text{ K } (0.43917 - 0.40378) \text{ kJ/kg-K} = \mathbf{0.46\ kW}$$

CV High T heat exchanger with Q from T_2, $T_3 = 32$°C to room 20°C

Entropy: $0 = \dot{m}\ (s_2 - s_3) - \dot{Q}_H/T_{house} + \dot{S}_{gen} \Rightarrow \dot{S}_{gen} = \dot{Q}_H/T_{house} - \dot{m}\ (s_2 - s_3)$

$$\dot{\Phi}_{destr.\ Hi\ T} = T_0 \dot{S}_{gen} = 298.15\ [\frac{9.1}{293.15} - 0.04393 \times (1.0779 - 0.40378)]$$

$$= \mathbf{0.426\ kW}$$

CV Low T heat exchanger, here $T_1 = -19.98$°C is constant as heat is absorbed,

the term $\dot{Q}_L/T_1$ is also equal to $\dot{m}\ (s_1 - s_4)$

$$\dot{\Phi}_{destr.\ Low\ T} = T_0 \dot{S}_{gen} = T_0[\dot{Q}_L/T_1 - \dot{Q}_L/T_{amb}] = 298.15(\frac{7.1}{253.17} - \frac{7.1}{268.15})$$

$$= \mathbf{0.467\ kW}$$

CV House walls that leaks heat out from 20°C to ambient 5°C.

$$\dot{\Phi}_{\text{destr. walls}} = T_0 \dot{S}_{\text{gen}} = T_0 [\dot{Q}_H/T_{\text{amb}} - \dot{Q}_H/T_{\text{house}}]$$

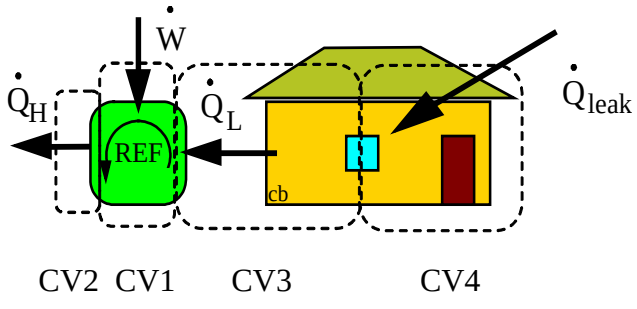
$$= 298.15\left(\frac{9.1}{268.15} - \frac{9.1}{293.15}\right) = \mathbf{0.863\ kW}$$

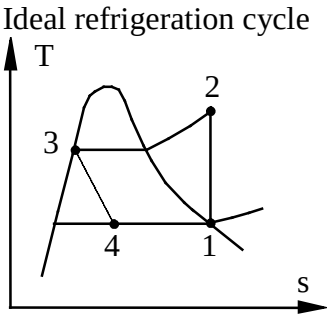
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.130

An air-conditioner using R-410A is used in cooling mode. The high pressure is 3000 kPa and the low pressure is 800 kPa. It cools a house at 20°C with a rate of 12 kW and the outside ambient is at 35°C. Find the destruction of exergy 4 places: 1) inside the refrigerator, 2) in the high T heat exchanger, 3) in the low T heat exchanger, and 4) in the house walls/windows etc. that separates the inside from the outside of the house.

The exergy destruction can be found from the exergy balance or from the entropy generation for each control volume





The control volumes 1-4 correspond to the exergy destruction locations. To answer the first one and to find the COP and the high T heat transfer we must analyze the refrigeration cycle.

State 1 (800 kPa, x = 1): $h_1 = 279.14$ kJ/kg, $s_1 = 1.0367$ kJ/kgK, $T_1 = 0.05$°C

State 2 (3000 kPa, s = s_1): $h_2 = 315.58$ kJ/kg, $T_2 = 70.5$ °C

State 3 (3000 kPa, x = 0): $h_3 = 141.78$ kJ/kg, $s_3 = 0.5011$ kJ/kgK, $T_3 = 49.07$ °C

State 4 (800 kPa, h = h_3): $x_4 = (141.78 - 57.8365)/221.304 = 0.37931$

$s_4 = 0.22667 + x_4\ 0.81003 = 0.53392$ kJ/kgK

Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 279.14 - 141.78 = 137.36$ kJ/kg

Condenser: $q_H = h_2 - h_3 = 315.58 - 141.78 = 173.8$ kJ/kg

Compressor: $w_c = h_2 - h_1 = 315.58 - 279.14 = 36.44$ kJ/kg,

$\dot{m} = \dot{Q}_L / q_L = 12$ kW/137.36 kJ/kg = 0.08736 kg/s

COP: $\beta = q_L/w_c = 137.36/36.44 = 3.7695$

$\dot{W} = \dot{Q}_L / \beta = 12$ kW/3.7695 = 3.183 kW; $\dot{Q}_H = \dot{W} + \dot{Q}_L = 15.183$ kW

CV1. The only entropy generation is in the valve:

$\dot{\Phi}_{destr.\ ref} = T_0\ \dot{S}_{gen} = \dot{m}\ T_0\ (s_4 - s_3)$

= 0.08736 kg/s × 298.15 K (0.53392 - 0.5011) kJ/kg-K = **0.855 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

CV2. The heat transfer goes to the ambient from the 2-3 condenser process.

Entropy Eq.: $0 = \dot{m}\,(s_2 - s_3) - \dot{Q}_H/T_{amb} + \dot{S}_{gen}$

$$\dot{\Phi}_{destr.\ Hi\ T} = T_0\,\dot{S}_{gen} = T_0\left[\,\dot{Q}_H/T_{amb} - \dot{m}\,(s_2 - s_3)\right]$$
$$= 298.15[\ 15.183/308.15 - 0.08736(1.0367 - 0.5011)]$$
$$= \mathbf{0.74\ kW}$$

CV3. Low T heat exchanger, here $T_1 = 0.05^{o}C$ is constant as heat is absorbed,

the term $\dot{Q}_L/T_1$ is also equal to $\dot{m}\,(s_1 - s_4)$

$$\dot{\Phi}_{destr.\ Low\ T} = T_0\,\dot{S}_{gen} = T_0[\dot{Q}_L/T_1 - \dot{Q}_L/T_{house}] = 298.15\left(\frac{12}{273.2} - \frac{12}{293.15}\right)$$
$$= \mathbf{0.891\ kW}$$

CV House walls that leaks heat from ambient $35^{o}C$ to house $20^{o}C$.

$$\dot{\Phi}_{destr.\ walls} = T_0\,\dot{S}_{gen} = T_0\,[\dot{Q}_L/T_{house} - \dot{Q}_L/T_{amb}]$$
$$= 298.15\left(\frac{12}{293.15} - \frac{12}{308.15}\right) = \mathbf{0.594\ kW}$$

The 4 destruction terms do not quite add up to the work input (3.183 kW) as the reference T =298.15 K = 25C, had we used 308.15 K instead they would add to the work term exactly.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.131

Assume the house in the previous problem has a combined 12000 kg hard wood, 2500 kg gypsum plates (Cp = 1 kJ/kg-K) and 750 kg steel all of which is at 20^{o}C. If the air conditioner is turned off how fast does the house heat up (^{o}C/s)?

Since the A/C cools the house at a rate of 12 kW it means there must be a leak into the house of 12 kW coming from the warmer ambient. As the A/C is truned off it then heats with a rate of 12 kW. As the house T goes up that rate drops exponentially in time until the house reaches the ambient 35C.

Energy Eq. house: $$\frac{dE}{dt} = \frac{dU}{dt} = m\,C\frac{dT}{dt} = \dot{Q}_{leak}$$

The thermal capacity is

$$m\,C = (mC)_{wood} + (mC)_{gypsum} + (mC)_{steel}$$
$$= 12\,000 \times 1.26 + 2500 \times 1 + 750 \times 0.46 = 17\,965 \text{ kJ/K}$$

Then

$$\frac{dT}{dt} = \dot{Q}_{leak} / m\,C = 12 \text{ kW} / 17\,965 \text{ kJ/K} = \mathbf{0.000668\ K/s}$$

9.132

Assume the house in problem 9.129 has a combined 12000 kg hard wood, 2500 kg gypsum plates (Cp = 1 kJ/kg-K) and 750 kg steel all of which is at 20^{o}C. If the heat pump is turned off how fast does the house cool down (^{o}C/s)

Since the heat pump heats the house at a rate of 9.1 kW it means there must be a leak out of the house of 9.1 kW going to the colder ambient. As the heat pump is truned off the house then cools with a rate of 9.1 kW. As the house T drops the rate drops exponentially in time until the house reaches the ambient -5C.

Energy Eq. house: $$\frac{dE}{dt} = \frac{dU}{dt} = m\,C\frac{dT}{dt} = -\dot{Q}_{leak}$$

The thermal capacity is

$$m\,C = (mC)_{wood} + (mC)_{gypsum} + (mC)_{steel}$$
$$= 12\,000 \times 1.26 + 2500 \times 1 + 750 \times 0.46 = 17\,965 \text{ kJ/K}$$

Then

$$\frac{dT}{dt} = -\dot{Q}_{leak}/\,m\,C = -9.1 \text{ kW} / 17\,965 \text{ kJ/K} = \mathbf{-0.000506\ K/s}$$

Combined Cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.133

A binary system power plant uses mercury for the high-temperature cycle and water for the low-temperature cycle, as shown in Fig. 12.20. The temperatures and pressures are shown in the corresponding *T–s* diagram. The maximum temperature in the steam cycle is where the steam leaves the superheater at point 4 where it is 500°C. Determine the ratio of the mass flow rate of mercury to the mass flow rate of water in the heat exchanger that condenses mercury and boils the water and the thermal efficiency of this ideal cycle.

The following saturation properties for mercury are known

P, MPa	T_g, °C	h_f, kJ/kg	h_g, kJ/kg	s_f kJ/kgK	s_g, kJ/kgK
0.04	309	42.21	335.64	0.1034	0.6073
1.60	562	75.37	364.04	0.1498	0.4954

Solution:

For the mercury cycle:

$$s_d = s_c = 0.4954 = 0.1034 + x_d \times 0.5039, \quad x_d = 0.7779$$

$$h_b = h_a - w_{P\,HG} \approx h_a \text{ (since } v_F \text{ is very small)}$$

$$q_H = h_c - h_a = 364.04 - 42.21 = 321.83 \text{ kJ/kg}$$

$$q_L = h_d - h_a = 270.48 - 42.21 = 228.27 \text{ kJ/kg}$$

For the steam cycle:

$$s_5 = s_4 = 7.0097 = 0.6493 + x_5 \times 7.5009, \quad x_5 = 0.8480$$

$$h_5 = 191.83 + 0.848 \times 2392.8 = 2220.8$$

$$w_P \approx v_1(P_2 - P_1) = 0.00101(4688 - 10) = 4.7 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 191.8 + 4.7 = 196.5$$

$$q_H \text{ (from Hg)} = h_3 - h_2 = 2769.9 - 196.5 = 2600.4$$

$$q_H \text{ (ext. source)} = h_4 - h_3 = 3437.4 - 2796.9 = 640.5$$

CV: Hg condenser - H_2O boiler: 1st law: $m_{Hg}(h_d - h_a) = m_{H2O}(h_3 - h_2)$

$$m_{Hg}/m_{H2O} = \frac{2796.9 - 196.5}{270.48 - 42.21} = \mathbf{11.392}$$

$$q_{H\,TOTAL} = (m_{Hg}/m_{H2O})(h_c - h_b) + (h_4 - h_3) \quad \text{(for 1 kg } H_2O\text{)}$$

$$= 11.392 \times 321.83 + 640.5 = 4306.8 \text{ kJ}$$

All q_L is from the H_2O condenser:

$$q_L = h_5 - h_1 = 2220.8 - 191.8 = 2029.0 \text{ kJ}$$

$$w_{NET} = q_H - q_L = 4306.8 - 2029.0 = 2277.8 \text{ kJ}$$

$$\eta_{TH} = w_{NET}/q_H = 2277.8/4306.8 = \mathbf{0.529}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.134

A Rankine steam power plant should operate with a high pressure of 3 MPa, a low pressure of 10 kPa, and the boiler exit temperature should be 500°C. The available high-temperature source is the exhaust of 175 kg/s air at 600°C from a gas turbine. If the boiler operates as a counter flowing heat exchanger where the temperature difference at the pinch point is 20°C, find the maximum water mass flow rate possible and the air exit temperature.

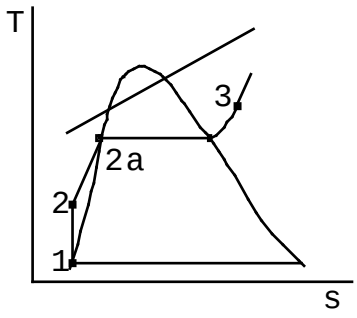
Solution:

C.V. Pump

$w_P = h_2 - h_1 = v_1(P_2 - P_1)$

$= 0.00101(3000 - 10) = 3.02$ kJ/kg

$h_2 = h_1 + w_P = 191.83 + 3.02 = 194.85$ kJ/kg

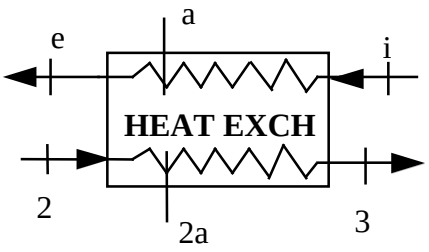


Heat exchanger water states

State 2a: $T_{2a} = T_{SAT} = 233.9$ °C

$h_{2a} = 1008.42$ kJ/kg

State 3: $h_3 = 3456.5$ kJ/kg



Heat exchanger air states

inlet: $h_{air,in} = 903.16$ kJ/kg

State 2a: $h_{air}(T_{2a} + 20) = 531.28$ kJ/kg

Air temperature should be 253.9°C at the point where the water is at state 2a.

C.V. Section 2a-3, i-a

$$\dot{m}_{H_2O}(h_3 - h_{2a}) = \dot{m}_{air}(h_i - h_a)$$

$$\dot{m}_{H_2O} = 175 \frac{903.16 - 531.28}{3456.5 - 1008.42} = \mathbf{26.584\ kg/s}$$

Take C.V. Total: $\dot{m}_{H_2O}(h_3 - h_2) = \dot{m}_{air}(h_i - h_e)$

$\Rightarrow \quad h_e = h_i - \dot{m}_{H_2O}(h_3 - h_2)/\dot{m}_{air}$

$= 903.6 - 26.584(3456.5 - 194.85)/175 = 408.13$ kJ/kg

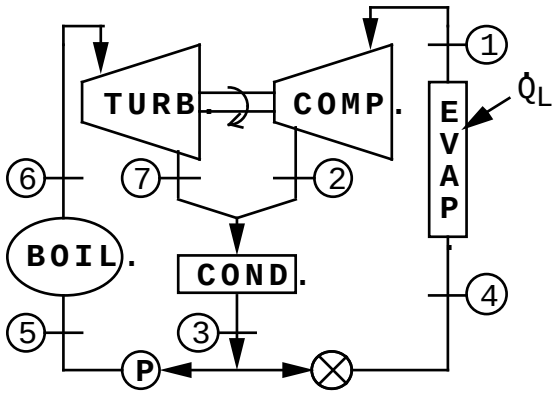
$\Rightarrow \quad T_e = 406.7$ K = **133.6 °C**, $T_e > T_2 = 46.5$ °C OK.

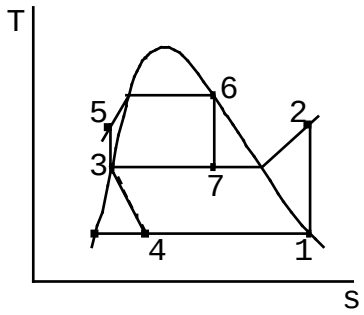
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.135

Consider an ideal dual-loop heat-powered refrigeration cycle using R-134a as the working fluid, as shown in Fig. P9.135. Saturated vapor at 90°C leaves the boiler and expands in the turbine to the condenser pressure. Saturated vapor at −15°C leaves the evaporator and is compressed to the condenser pressure. The ratio of the flows through the two loops is such that the turbine produces just enough power to drive the compressor. The two exiting streams mix together and enter the condenser. Saturated liquid leaving the condenser at 45°C is then separated into two streams in the necessary proportions. Determine the ratio of mass flow rate through the power loop to that through the refrigeration loop. Find also the performance of the cycle, in terms of the ratio $\dot{Q}_L / \dot{Q}_H$.

Solution:





T_1 = -15 °C sat. vap.

Table B.5.1 $T_6 = 90^oC$ sat. vapor => $P_5 = P_6 = 3.2445$ MPa

Table B.5.1 $T_3 = 45^oC$ sat. liquid => $P_2 = P_3 = P_7 = 1.1602$ MPa

$h_1 = 389.2$; $h_3 = h_4 = 264.11$; $h_6 = 425.7$ kJ/kg

C.V. Turbine

$s_7 = s_6 = 1.6671 = 1.2145 + x_7 \times 0.4962$; $x_7 = 0.9121$

$h_7 = 264.11 + 0.9121 \times 157.85 = 408.08$ kJ/kg

C.V. Compressor (computer tables are used for this due to value of P or you do a double linear interpolation between 1000 and 1200 kPa to get 1160.2 kPa)

$s_2 = s_1 = 1.7354$, P_2 => $T_2 = 52.27^oC$, $h_2 = 429.9$ kJ/kg

CV: turbine + compressor

Continuity Eq.: $\dot{m}_1 = \dot{m}_2$, $\dot{m}_6 = \dot{m}_7$;

Energy Eq.: $\dot{m}_1 h_1 + \dot{m}_6 h_6 = \dot{m}_1 h_2 + \dot{m}_6 h_7$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$\dot{m}_6/\dot{m}_1 = \frac{h_2 - h_1}{h_6 - h_7} = \frac{429.9 - 389.2}{425.7 - 408.08} = \mathbf{2.31}$$

CV: pump

$$w_P = v_3(P_5 - P_3) = 0.00089(3244.5 - 1160.2) = 1.855 \text{ kJ/kg}$$

$$h_5 = h_3 + w_P = 264.11 + 1.855 = 265.96 \text{ kJ/kg}$$

CV: evaporator $\Rightarrow \quad \dot{Q}_L = \dot{m}_1 (h_1 - h_4)$

CV: boiler $\Rightarrow \quad \dot{Q}_H = \dot{m}_6 (h_6 - h_5)$

$$\beta = \frac{\dot{Q}_L}{\dot{Q}_H} = \frac{\dot{m}_1(h_1 - h_4)}{\dot{m}_6(h_6 - h_5)} = \frac{389.2 - 264.11}{2.31\ (425.7 - 265.96)} = \mathbf{0.34}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.136

For a cryogenic experiment heat should be removed from a space at 75 K to a reservoir at 180 K. A heat pump is designed to use nitrogen and methane in a cascade arrangement (see Fig. 9.28), where the high temperature of the nitrogen condensation is at 10 K higher than the low-temperature evaporation of the methane. The two other phase changes take place at the listed reservoir temperatures. Find the saturation temperatures in the heat exchanger between the two cycles that gives the best coefficient of performance for the overall system.

The nitrogen cycle is the bottom cycle and the methane cycle is the top cycle. Both are standard refrigeration cycles.

$T_{Hm} = 180\ K = T_{3m}$, $T_{LN} = 75\ K = T_{4N} = T_{1N}$

$T_{Lm} = T_{4m} = T_{1m} = T_{3N} - 10$, Trial and error on T_{3N} or T_{Lm}.

For each cycle we have,

$$-w_C = h_2 - h_1, \quad s_2 = s_1, \quad -q_H = h_2 - h_3, \quad q_L = h_1 - h_4 = h_1 - h_3$$

Nitrogen: $T_4 = T_1 = 75\ K \Rightarrow h_1 = 74.867\ kJ/kg,\ s_1 = 5.4609\ kJ/kg\ K$

N_2	T_3	h_3	P_2	h_2	$-w_c$	$-q_H$	q_L
a)	120	-17.605	2.5125	202.96	128.1	220.57	92.47
b)	115	-34.308	1.9388	188.35	113.5	222.66	109.18
c)	110	-48.446	1.4672	173.88	99.0	222.33	123.31

Methane: $T_3 = 180\ K \Rightarrow h_3 = -0.5\ kJ/kg,\ P_2 = 3.28655\ MPa$

CH_4	T_4	h_1	s_1	h_2	$-w_c$	$-q_H$	q_L
a)	110	221	9.548	540.3	319.3	540.8	221.5
b)	105	212.2	9.691	581.1	368.9	581.6	212.7
c)	100	202.9	9.851	629.7	426.8	630.2	203.4

The heat exchanger that connects the cycles transfers a Q

$$\dot{Q}_{Hn} = q_{Hn}\,\dot{m}_n = \dot{Q}_{Lm} = q_{Lm}\,\dot{m}_m \Rightarrow \dot{m}_m/\dot{m}_n = q_{Hn}/q_{Lm}$$

The overall unit then has

$$\dot{Q}_{L\ 75\ K} = \dot{m}_n\, q_{Ln}\ ; \quad \dot{W}_{tot\ in} = -(\dot{m}_n w_{cn} + \dot{m}_m w_{cm})$$

$$\beta = \dot{Q}_{L\ 75\ K}/\dot{W}_{tot\ in} = q_{Ln}/[-w_{cn} - (\dot{m}_m/\dot{m}_n) w_{cm}]$$

Case	$\dot{m}_m/\dot{m}_n$	$w_{cn}+(\dot{m}_m/\dot{m}_n)w_{cm}$	β
a)	0.996	446.06	0.207
b)	1.047	499.65	0.219
c)	1.093	565.49	0.218

A maximum coefficient of performance is between case b) and c).

9.137

For Problem 9.134, determine the change of exergy of the water flow and that of the air flow. Use these to determine a second law efficiency for the boiler heat exchanger.

From solution to 9.134:

$\dot{m}_{H2O}$ = 26.584 kg/s, h_2 = 194.85 kJ/kg, s_2 = 0.6587 kJ/kg K

h_3 = 3456.5 kJ/kg, s_3 = 7.2338, $s°_{Ti}$ = 7.9820, $s°_{Te}$ = 7.1762 kJ/kg K

h_i = 903.16 kJ/kg, h_e = 408.13 kJ/kg

$\psi_3 - \psi_2 = h_3 - h_2 - T_0(s_3 - s_2)$ = 1301.28 kJ/kg

$\psi_i - \psi_e = h_i - h_e - T_0(s°_{Ti} - s°_{Te})$ = 254.78 kJ/kg

$$\eta_{II} = \frac{(\psi_3 - \psi_2)\,\dot{m}_{H2O}}{(\psi_i - \psi_e)\,\dot{m}_{air}} = \frac{1301.28 \times 26.584}{254.78 \times 175} = \mathbf{0.776}$$

Review Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.138

Do Problem 9.31 with R-134a as the working fluid in the Rankine cycle.

Consider the ammonia Rankine-cycle power plant shown in Fig. P9.31, a plant that was designed to operate in a location where the ocean water temperature is 25°C near the surface and 5°C at some greater depth. The mass flow rate of the working fluid is 1000 kg/s.

a. Determine the turbine power output and the pump power input for the cycle.
b. Determine the mass flow rate of water through each heat exchanger.
c. What is the thermal efficiency of this power plant?

Solution:

a) Turbine

$s_2 = s_1 = 1.7183 = 1.0485 + x_2 \times 0.6733 \quad \Rightarrow \quad x_2 = 0.9948$

$h_2 = 213.58 + 0.9948 \times 190.65 = 403.24$ kJ/kg

$w_T = h_1 - h_2 = 409.84 - 403.24 = 6.6$ kJ/kg

$\dot{W}_T = \dot{m} w_T = 6600$ kW

Pump: $w_P \approx v_3(P_4 - P_3) = 0.000794(572.8 - 415.8) = 0.125$ kJ/kg

$w_P = w_P / \eta_S = 0.125 \quad \Rightarrow \quad \dot{W}_P = \dot{m} w_P =$ **125 kW**

b) Consider the condenser heat transfer to the low T water

$\dot{Q}_{\text{to low T H2O}} = 1000(403.24 - 213.58) = 189\,660$ kW

$\dot{m}_{\text{low T H2O}} = \dfrac{189660}{29.38 - 20.98} =$ **22 579 kg/s**

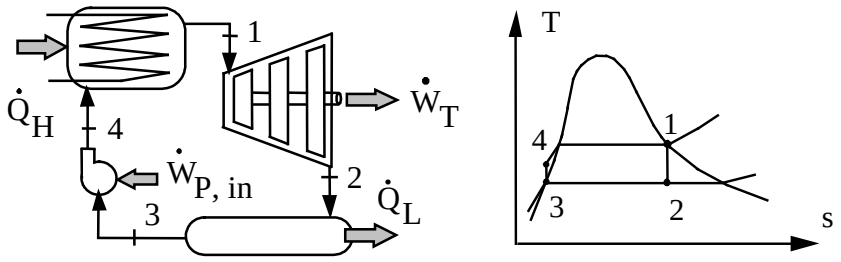
$h_4 = h_3 - w_P = 213.58 + 0.125 = 213.71$ kJ/kg

Now consider the boiler heat transfer from the high T water

$\dot{Q}_{\text{from high T H2O}} = 1000(409.84 - 213.71) = 196\,130$ kW

$\dot{m}_{\text{high T H2O}} = \dfrac{196130}{104.87 - 96.50} =$ **23 432 kg/s**

c) $\eta_{TH} = \dot{W}_{NET} / \dot{Q}_H = \dfrac{6600 - 125}{196130} =$ **0.033**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.139

A simple steam power plant is said to have the four states as listed: 1: (20°C, 100 kPa), 2: (25°C, 1 MPa), 3: (1000°C, 1 MPa), 4: (250°C, 100 kPa) with an energy source at 1100°C and it rejects energy to a 0°C ambient. Is this cycle possible? Are any of the devices impossible?

Solution:

The cycle should be like Figure 9.3 for an ideal or Fig.9.15 for an actual pump and turbine in the cycle. We look the properties up in Table B.1:

State 1: $h_1 = 83.94$, $s_1 = 0.2966$ State 2: $h_2 = 104.87$, $s_2 = 0.3673$

State 3: $h_3 = 4637.6$, $s_3 = 8.9119$ State 4: $h_4 = 2974.3$, $s_4 = 8.0332$

We may check the overall cycle performance

Boiler: $q_H = h_3 - h_2 = 4637.6 - 104.87 = 4532.7$ kJ/kg

Condenser: $q_L = h_4 - h_1 = 2974.3 - 83.94 = 2890.4$ kJ/kg

$\eta_{cycle} = q_{net} / q_H = (q_H - q_L) / q_H = 1642.3 / 4532.7 = 0.362$

$$\eta_{carnot} = 1 - T_L / T_H = 1 - \frac{273.15}{273.15 + 1100} = \mathbf{0.80} > \eta_{cycle} \quad \mathbf{OK}$$

Check the second law for the individual devices:

C.V. Boiler plus wall to reservoir

$$s_{gen} = s_3 - s_2 - \frac{q_H}{T_{res}} = 8.9119 - 0.3673 - \frac{4532.7}{1373} = 5.24 \text{ kJ/kg K} > 0 \quad \mathbf{OK}$$

C.V. Condenser plus wall to reservoir

$$s_{gen} = s_1 - s_4 + \frac{q_L}{T_{res}} = 0.2966 - 8.0332 + \frac{2890.4}{273} = 2.845 \text{ kJ/kg K} > 0 \quad \mathbf{OK}$$

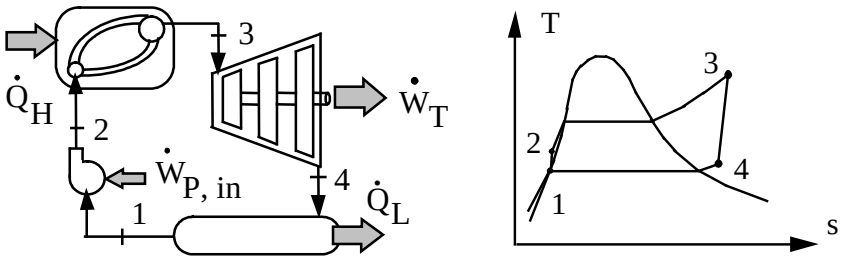
C.V. Pump: $w_p = h_2 - h_1 = 20.93$ kJ/kg ;

$s_{gen} = s_2 - s_1 = 0.3673 - 0.2966 = 0.0707$ kJ/kg K > 0 **OK**

C.V. Turbine: $w_T = h_3 - h_4 = 4637.6 - 2974.3 = 1663.3$ kJ/kg

$s_{gen} = s_4 - s_3 = 8.0332 - 8.9119 = - 0.8787$ kJ/kg K

$s_{gen} < 0$ **NOT POSSIBLE**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.140

A supercritical power plant has a high pressure of 30 MPa and the boiler heats the water to 500^{o}C with 45^{o}C in the condenser. To avoid a quality in the turbine of less than 92% determine the pressure(s) at which to make reheat (look only at the P's listed in Table B.1 do not interpolate between them) if the reheat takes it up to 400^{o}C.

Let us work backwards from the lowest towards the highest pressures. What state should the steam come from if the final exit state is at 45^{o}C and x = 0.92?

State 45^{o}C and x = 0.92: s = 0.6386 + 0.92 × 7.5261 = 7.5626 kJ/kgK

The reheat should then produce 400^{o}C, s ≥ 7.5626 kJ/kgK ,

B.1.2: At **P = 800 kPa**, 400^{o}C, s = 7.5715 kJ/kgK.
At 800 kPa, x = 0.92: s = 2.0461 + 0.92 × 4.6166 = 6.2934 kJ/kgK

The next reheat should then produce 400^{o}C, s ≥ 6.2934 kJ/kgK ,

B.1.2: At **P = 8000 kPa**, 400^{o}C, s = 6.3633 kJ/kgK.
At 8000 kPa, x = 0.92: s = 3.2067 + 0.92 × 2.5365 = 5.5403 kJ/kgK

At 30 MPa, 500^{o}C : s = 5.7904 kJ/kgK so this is fine.

Comment: In reality you do not want any two-phase states in the high pressure sections of the turbine, so if that is a condition you expand from the inlet to a state the closest to sat. vapor (8000 kPa) reheat to 400 C, then expand again to near sat. vapor giving about 2000 kPa, reheat to 400 C and expand again for a final reheat at 500 kPa.

The processes for the different steps are shown generated by CATT3 using the plot process from the Options menu drop down select plot proces.

Starting from the 45^{o}C and x = 0.92 a process is plotted with constant s to 400^{o}C. Then starting with 400^{o}C, 800 kPa a constant pressure process is plotted to x = 0.92 followed by another constant s process up to 400^{o}C. Again a constant pressure process from 400^{o}C, 8000 kPa to x = 0.92 followed by a constant s process from the original 30 MPa, 500^{o}C down to 8000 kPa to verify the final step. The curves do not match precisely as the table entries were chosen to match the hand calculations.

The curves are shown on the following page.

9.141

A dairy farmer needs to heat a 0.1 kg/s flow of milk from room temperature 20°C to 60°C to pasteurize it and then send the flow through a cooler bringing it to 10° C for storage. He wants to by a heat pump to do this and finds one using R-134a with a high pressure of 3 MPa and a low pressure of 300 kPa. The farmer is very clever and uses the heat pump to heat the milk in a heat exchanger after which the milk flows through the evaporator heat exchanger to cool it. Find the power required to run the heat pump so it can do both the heating and the cooling assuming milk has the properties of water. Is there any excess heating or cooling capacity? What is the total rate of exergy destruction by running this system?

Do the refrigeration cycle.

State 1 (300 kPa, x = 1): $h_1 = 398.69$ kJ/kg, $s_1 = 1.7259$ kJ/kgK, $T_1 = 0.56^oC$

State 2 (3000 kPa, s = s_1): $h_2 = 445.90$ kJ/kg, $T_2 = 95.5\ ^oC$

State 3 (3000 kPa, x = 0): $h_3 = 335.225$ kJ/kg, $s_3 = 1.4186$ kJ/kgK, $T_3 = 86.2^oC$

Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 398.69 - 335.225 = 63.465$ kJ/kg

Condenser: $q_H = h_2 - h_3 = 445.90 - 335.225 = 110.675$ kJ/kg

Compressor: $w_c = h_2 - h_1 = 445.90 - 398.69 = 47.21$ kJ/kg,

COP: $\beta = q_L/w_c = 63.465 / 47.21 = 1.344$

Since we need to cool more than we need to heat, the heat pump needs to be sized to the cooling. From the definition of COP and the milk heat transfer required:

$$\dot{Q}_L = \dot{m}C_p(T_2 - T_3) = 0.1 \times 4.18\ (60 - 10) = 20.9\ \text{kW} = \beta\ \dot{W}$$

$$\dot{Q}_{H\ milk} = \dot{m}C_p(T_2 - T_1) = 0.1 \times 4.18\ (60 - 20) = 16.72\ \text{kW}$$

$$\dot{W} = \dot{Q}_L / \beta = 20.9\ \text{kW}/1.344 = \mathbf{15.55\ kW}; \quad \dot{Q}_H = \dot{W} + \dot{Q}_L = 36.45\ \text{kW}$$

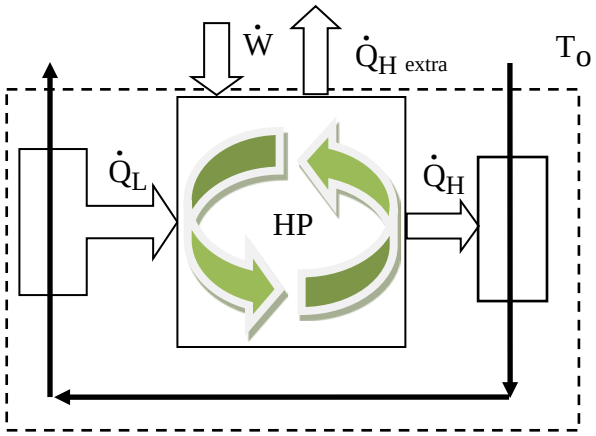
$$\dot{Q}_{H\ extra} = \dot{Q}_H - \dot{Q}_{H\ milk} = 36.45 - 16.72 = \mathbf{19.73\ kW}$$

For exergy we have work in and flow in with zero (T_o), heat dumped into the ambient also assumed zero and then the cold flow out with a positive exergy.

$$\dot{\Phi}_{flow\ out} = \dot{m}\ [\ h_3 - h_1 - T_o(s_3 - s_1)] = \dot{m}C_p[T_3 - T_1 - T_o \ln(T_3/T_1)]$$
$$= 0.1 \times 4.18\ [-10 - 293 \ln(283/293)] = 0.073\ \text{kW}$$

$$\dot{\Phi}_{destr} = \dot{W} - \dot{\Phi}_{flow\ out} = 15.55 - 0.073 = \mathbf{15.48\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*



If we take control volume total (as shown) then the s generation can be found

$$0 = \dot{m}\,(s_1 - s_3) - (\dot{Q}_H - \dot{Q}_{H\ milk})/T_o + \dot{S}_{gen}$$

and then $\dot{\Phi}_{destr} = T_o\,\dot{S}_{gen}$ giving the same result.

Comment: Clearly the extra heat out at 86°C could be useful and the cycle can be run with a slightly lower high pressure as it only need to heat the milk to 60°C.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.142

Consider an ideal combined reheat and regenerative cycle in which steam enters the high-pressure turbine at 3.0 MPa, 400°C, and is extracted to an open feedwater heater at 0.8 MPa with exit as saturated liquid. The remainder of the steam is reheated to 400°C at this pressure, 0.8 MPa, and is fed to the low-pressure turbine. The condenser pressure is 10 kPa. Calculate the thermal efficiency of the cycle and the net work per kilogram of steam.

Solution:

In this setup the flow is separated into fractions x and 1-x after coming out of T1. The two flows are recombined in the FWH.

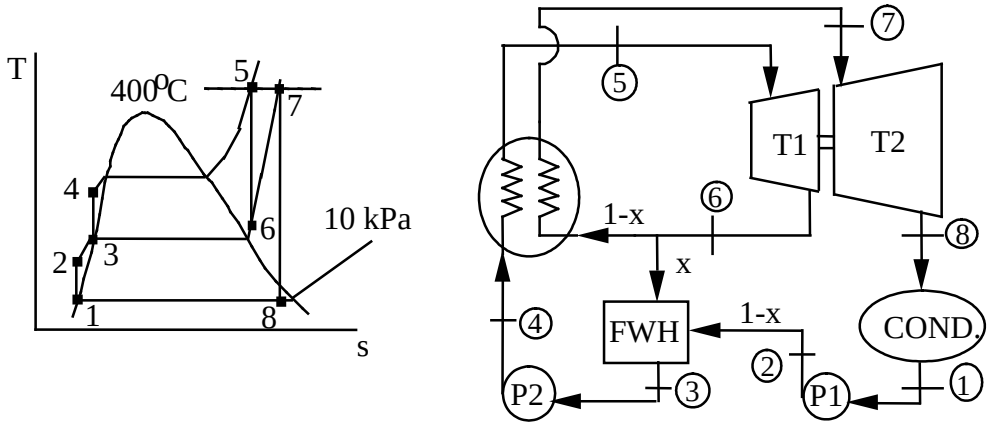
C.V. T1 $\quad s_6 = s_5 = 6.9211$ kJ/kg K $\quad \Rightarrow \quad h_6 = 2891.6$ kJ/kg

$$w_{T1} = h_5 - h_6 = 3230.82 - 2891.6 = 339.22 \text{ kJ/kg}$$

C.V. Pump 1:

$$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.00101(800 - 10) = 0.798 \text{ kJ/kg}$$

$$\Rightarrow \quad h_2 = h_1 + w_{P1} = 191.81 + 0.798 = 192.61 \text{ kJ/kg}$$



C.V. FWH, $\quad h_3 = h_f = 721.1$

Energy equation per unit mass flow exit at 3:

$$x\, h_6 + (1 - x)\, h_2 = h_3 \qquad \Rightarrow \quad x = \frac{h_3 - h_2}{h_6 - h_2} = \frac{721.1 - 192.61}{2891.6 - 192.61} = 0.1958$$

C.V. Pump 2

$$w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.001115(3000 - 800) = 2.45 \text{ kJ/kg}$$

$$\Rightarrow \quad h_4 = h_3 + w_{P2} = 721.1 + 2.45 = 723.55 \text{ kJ/kg}$$

C.V. Boiler/steam generator including reheater.

Total flow from 4 to 5 only fraction 1-x from 6 to 7

$$q_H = h_5 - h_4 + (1 - x)(h_7 - h_6) = 2507.3 + 301.95 = 2809.3 \text{ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

C.V. Turbine 2

$$s_8 = s_7 = 7.5715 \text{ kJ/kg K} \quad => \quad x_8 = (7.5715 - 0.6492)/7.501 = 0.92285$$

$$h_8 = h_f + x_8 \, h_{fg} = 191.81 + 0.92285 \times 2392.82 = 2400.0 \text{ kJ/kg}$$

$$w_{T2} = h_7 - h_8 = 3267.07 - 2400.02 = 867.05 \text{ kJ/kg}$$

Sum the work terms to get net work. Total flow through T1 only fraction 1-x through T2 and P1 and after FWH we have the total flow through P2.

$$w_{net} = w_{T1} + (1 - x) \, w_{T2} - (1 - x) \, w_{P1} - w_{P2}$$

$$= 339.2 + 697.3 - 0.64 - 2.45 = \mathbf{1033.41 \text{ kJ/kg}}$$

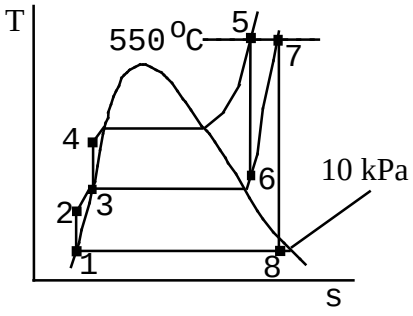
$$\eta_{cycle} = w_{net} / q_H = 1033.41 / 2809.3 = \mathbf{0.368}$$

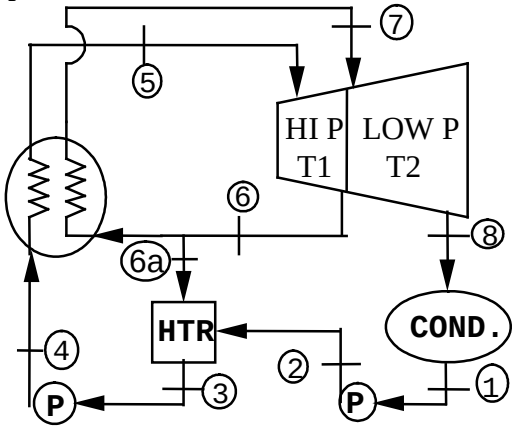
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.143

An ideal steam power plant is designed to operate on the combined reheat and regenerative cycle and to produce a net power output of 10 MW. Steam enters the high-pressure turbine at 8 MPa, 550°C, and is expanded to 0.6 MPa, at which pressure some of the steam is fed to an open feedwater heater, and the remainder is reheated to 550°C. The reheated steam is then expanded in the low-pressure turbine to 10 kPa. Determine the steam flow rate to the high-pressure turbine and the power required to drive each of the pumps.

a)





b) $-w_{P12} = 0.00101(600 - 10) = 0.6$ kJ/kg

$h_2 = h_1 - w_{P12} = 191.8 + 0.6 = 192.4$ kJ/kg

$-w_{P34} = 0.00101(8000 - 600) = 8.1$ kJ/kg

$h_4 = h_3 - w_{P34} = 670.6 + 8.1 = 678.7$; $h_5 = 3521.0$ kJ/kg,

$s_6 = s_5 = 6.8778 \Rightarrow T_6 = 182.32\ ^{o}C \quad h_6 = 2810.0$ kJ/kg,

$h_7 = 3591.9$, $s_8 = s_7 = 8.1348 = 0.6493 + x_8 \times 7.5009 \Rightarrow x_8 = 0.9979$

$h_8 = 191.83 + 0.9979 \times 2392.8 = 2579.7$ kJ/kg

CV: heater

Cont: $m_{6a} + m_2 = m_3 = 1$ kg, Energy Eq: $m_{6a}h_6 + m_2h_2 = m_3h_3$

$$m_{6a} = \frac{670.6 - 192.4}{2810.0 - 192.4} = 0.1827, \quad m_2 = m_7 = 1 - m_{6a} = 0.8173$$

CV: turbine $w_T = (h_5 - h_6) + (1 - m_{6a})(h_7 - h_8)$

$= 3521 - 2810 + 0.8173(3591.9 - 2579.7) = 1538.2$ kJ/kg

CV: pumps

$w_P = m_2w_{P12} + m_4w_{P34} = 0.8214\times(-0.6) + 1\times(-8.1) = -8.6$ kJ/kg

$w_{Net} = 1538.2 - 8.6 = 1529.6$ kJ/kg (m_5)

$\dot{m}_5 = \dot{W}_{Net}/w_{Net} = 10000/1529.6 =$ **6.53 kg/s**

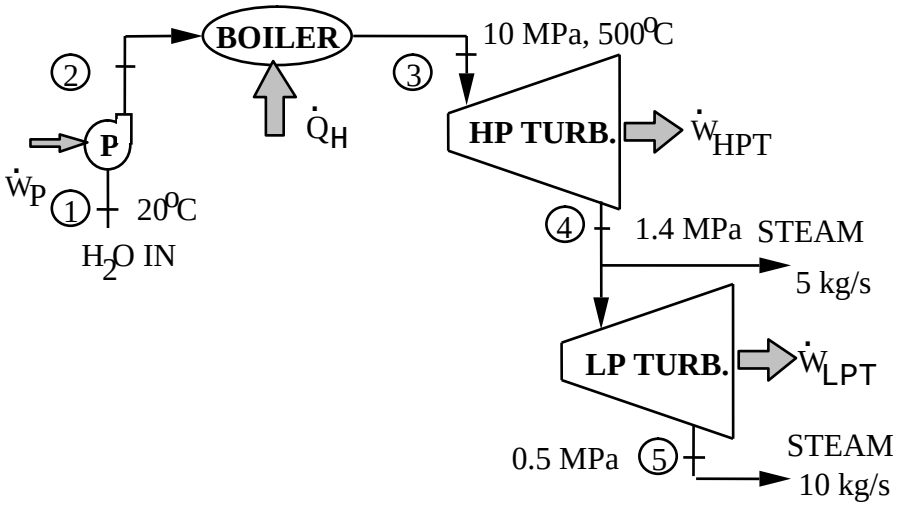
9.144

An industrial application has the following steam requirement: one 10-kg/s stream at a pressure of 0.5 MPa and one 5-kg/s stream at 1.4 MPa (both saturated or slightly superheated vapor). It is obtained by cogeneration, whereby a high-pressure boiler supplies steam at 10 MPa, 500°C to a reversible turbine. The required amount is withdrawn at 1.4 MPa, and the remainder is expanded in the low-pressure end of the turbine to 0.5 MPa providing the second required steam flow.

a. Determine the power output of the turbine and the heat transfer rate in the boiler.

b. Compute the rates needed were the steam generated in a low-pressure boiler without cogeneration. Assume that for each, 20°C liquid water is pumped to the required pressure and fed to a boiler.

Solution:



a) **With cogeneration**

high-pressure turbine.

$s_4 = s_3 = 6.5966$ kJ/kg K $\Rightarrow$ $T_4 = 219.9\ ^oC$, $h_4 = 2852.6$ kJ/kg

$w_{S\ HPT} = h_3 - h_4 = 3373.7 - 2852.6 = 521.1$ kJ/kg

low-pressure turbine

$s_5 = s_4 = 6.5966 = 1.8607 + x_5 \times 4.9606$, $x_5 = 0.9547$

$h_5 = 640.23 + 0.9547 \times 2108.5 = 2653.2$ kJ/kg

$w_{S\ LPT} = h_4 - h_5 = 2852.6 - 2653.2 = 199.4$ kJ/kg

$\dot{W}_{TURB} = 15 \times 521.1 + 10 \times 199.4 =$ **9810 kW**

$\dot{W}_P = 15 \times 0.001002\ (10\ 000 - 2.3) = 150.3$ kW

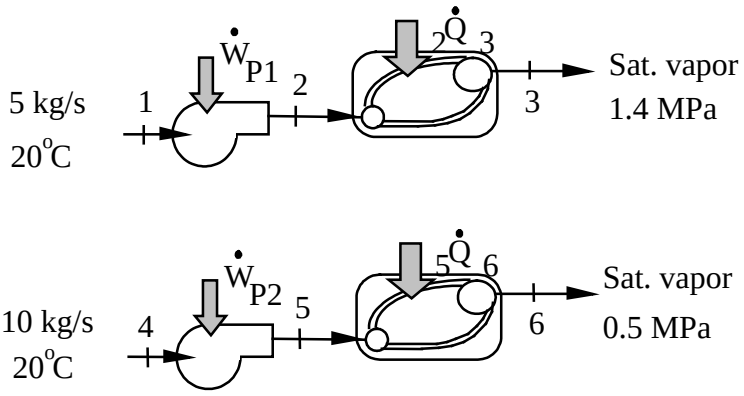
$h_2 = h_1 + w_P = 83.96 + 10.02 = 94.0$ kJ/kg

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$\dot{Q}_H = \dot{m}_1(h_3 - h_2) = 15(3373.7 - 94.0) = \mathbf{49\ 196\ kW}$$

b) **Without cogeneration**

This is to be compared to the amount of heat required to supply 5 kg/s of 1.4 MPa sat. vap. plus 10 kg/s of 0.5 MPa sat. vap. from 20°C water.



Pump 1 and boiler 1

$w_P = 0.001002(1400 - 2.3) = 14.0$ kJ/kg,

$h_2 = h_1 + w_P = 83.96 + 14.0 = 85.4$ kJ/kg

$_2\dot{Q}_3 = \dot{m}_1(h_3 - h_2) = 5(2790.0 - 85.4) = 13\ 523$ kW

$\dot{W}_{P1} = 5 \times 14.0 = 7$ kW

Pump 2 and boiler 2

$h_5 = h_4 + w_{P2} = 83.96 + 0.001002(500 - 2.3) = 84.5$ kJ/kg

$_5\dot{Q}_6 = \dot{m}_4(h_6 - h_5) = 10(2748.7 - 84.5) = 26\ 642$ kW

$\dot{W}_{P2} = 10 \times 0.5 = 5$ kW

Total $\dot{Q}_H = 13523 + 26642 =$ **40 165 kW**

Notice here that the extra heat transfer is about 9000 kW to run the turbines but that provides 9800 kW of work for electricity (a 100% conversion of the extra Q to W).

9.145

The effect of a number of open feedwater heaters on the thermal efficiency of an ideal cycle is to be studied. Steam leaves the steam generator at 20 MPa, 600°C, and the cycle has a condenser pressure of 10 kPa. Determine the thermal efficiency for each of the following cases. **A:** No feedwater heater. **B**: One feedwater heater operating at 1 MPa. **C:** Two feedwater heaters, one operating at 3 MPa and the other at 0.2 MPa.

a) no feed water heater

$$w_P = \int_1^2 v dP$$

$$\approx 0.00101(20000 - 10)$$

$$= 20.2 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 191.8 + 20.2 = 212.0$$

$$s_4 = s_3 = 6.5048$$

$$= 0.6493 + x_4 \times 7.5009$$

$$x_4 = 0.78064$$

$$h_4 = 191.83 + 0.780\,64 \times 2392.8$$

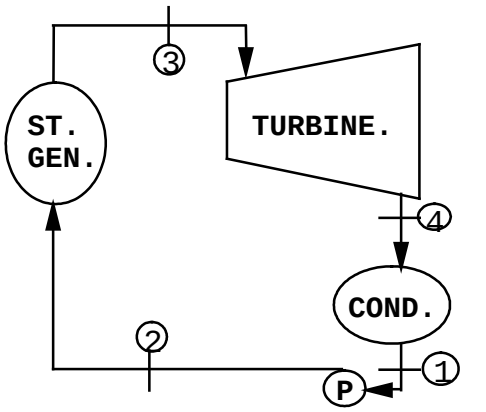
$$= 2059.7$$

$$w_T = h_3 - h_4 = 3537.6 - 2059.7$$

$$= 1477.9 \text{ kJ/kg}$$

$$w_N = w_T - w_P = 1477.9 - 20.2 = 1457.7$$

$$q_H = h_3 - h_2 = 3537.6 - 212.0 = 3325.6$$



$$\eta_{TH} = \frac{w_N}{q_H} = \frac{1457.7}{3325.6} = \mathbf{0.438}$$

b) one feedwater heater

$$w_{P12} = 0.00101(1000 - 10)$$

$$= 1.0 \text{ kJ/kg}$$

$$h_2 = h_1 + w_{P12} = 191.8 + 1.0 = 192.8$$

$$w_{P34} = 0.001127\ (20000 - 1000)$$

$$= 21.4 \text{ kJ/kg}$$

$$h_4 = h_3 + w_{P34} = 762.8 + 21.4 = 784.2$$

$$s_6 = s_5 = 6.5048$$

$$= 2.1387 + x_6 \times 4.4478$$

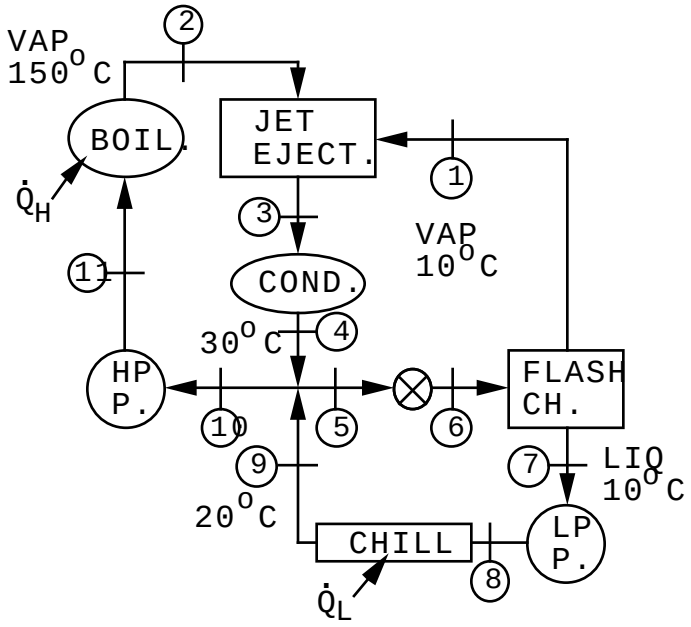
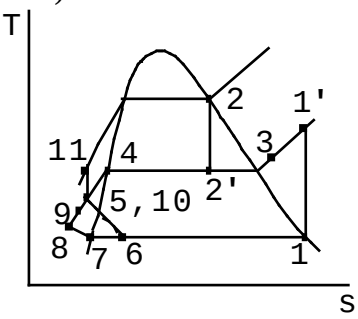
9.146

A jet ejector, a device with no moving parts, functions as the equivalent of a coupled turbine-compressor unit (see Problems 7.165 and 7.172). Thus, the turbine-compressor in the dual-loop cycle of Fig. P9.135 could be replaced by a jet ejector. The primary stream of the jet ejector enters from the boiler, the secondary stream enters from the evaporator, and the discharge flows to the condenser. Alternatively, a jet ejector may be used with water as the working fluid. The purpose of the device is to chill water, usually for an air-conditioning system. In this application the physical setup is as shown in Fig. P9.146. Using the data given on the diagram, evaluate the performance of this cycle in terms of the ratio Q_L/Q_H.

a. Assume an ideal cycle.
b. Assume an ejector efficiency of 20% (see Problem 7.172).





$T_1 = T_7 = 10\ ^oC$

$T_2 = 150\ ^oC$

$T_4 = 30\ ^oC$

$T_9 = 20\ ^oC$

Assume $T_5 = T_{10}$

(from mixing streams 4 & 9).

$P_3 = P_4 = P_5 = P_8 = P_9 = P_{10} = P_{G\ 30\ ^oC} = 4.246$ kPa

$P_{11} = P_2 = P_{G\ 150^oC} = 475.8$ kPa, $P_1 = P_6 = P_7 = P_{G\ 10^oC} = 1.2276$ kPa

Cont: $\dot{m}_1 + \dot{m}_9 = \dot{m}_5 + \dot{m}_{10}$, $\dot{m}_5 = \dot{m}_6 = \dot{m}_7 + \dot{m}_1$

$\dot{m}_7 = \dot{m}_8 = \dot{m}_9$, $\dot{m}_{10} = \dot{m}_{11} = \dot{m}_2$, $\dot{m}_3 = \dot{m}_4$

a) $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$; ideal jet ejector

$s_1' = s_1$ & $s_2' = s_2$ (1' & 2' at $P_3 = P_4$)

then, $\dot{m}_1(h_1' - h_1) = \dot{m}_2(h_2 - h_2')$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

From $s_2' = s_2 = 0.4369 + x_2' \times 8.0164$; $x_2' = 0.7985$

$h_2' = 125.79 + 0.7985 \times 2430.5 = 2066.5$ kJ/kg

From $s_1' = s_1 = 8.9008 \Rightarrow T_1' = 112$ °C, $h_1' = 2710.4$ kJ/kg

$$\Rightarrow \dot{m}_1/\dot{m}_2 = \frac{2746.5 - 2066.5}{2710.4 - 2519.8} = 3.5677$$

Also $h_4 = 125.79$ kJ/kg, $h_7 = 42.01$ kJ/kg, $h_9 = 83.96$ kJ/kg

Mixing of streams 4 & 9 $\Rightarrow$ 5 & 10:

$$(\dot{m}_1 + \dot{m}_2)h_4 + \dot{m}_7 h_9 = (\dot{m}_7 + \dot{m}_1 + \dot{m}_2)h_{5=10}$$

Flash chamber (since $h_6 = h_5$) : $(\dot{m}_7+\dot{m}_1)h_{5=10} = \dot{m}_1 h_1 + \dot{m}_7 h_1$

$\Rightarrow$ using the primary stream $\dot{m}_2 = 1$ kg/s:

$$4.5677 \times 125.79 + \dot{m}_7 \times 83.96 = (\dot{m}_7 + 4.5677)h_5$$

$$\& \ (\dot{m}_7 + 3.5677)h_5 = 3.5677 \times 2519.8 + \dot{m}_7 \times 42.01$$

Solving, $\dot{m}_7 = 202.627$ & $h_5 = 84.88$ kJ/kg

LP pump: $-w_{LP\,P} = 0.0010(4.246 - 1.2276) = 0.003$ kJ/kg

$h_8 = h_7 - w_{LP\,P} = 42.01 + 0.003 = 42.01$ kJ/kg

Chiller: $\dot{Q}_L = \dot{m}_7(h_9-h_8) = 202.627(83.96 - 42.01) = 8500$ kW (for $\dot{m}_2 = 1$)

HP pump: $-w_{HP\,P} = 0.001002(475.8 - 4.246) = 0.47$ kJ/kg

$h_{11} = h_{10} - w_{HP\,P} = 84.88 + 0.47 = 85.35$ kJ/kg

Boiler: $\dot{Q}_{11} = \dot{m}_{11}(h_2 - h_{11}) = 1(2746.5 - 85.35) = 2661.1$ kW

$\Rightarrow \dot{Q}_L/\dot{Q}_H = 8500/2661.1 =$ **3.194**

b) Jet eject. eff. $= (\dot{m}_1/\dot{m}_2)_{ACT}/(\dot{m}_1/\dot{m}_2)_{IDEAL} = 0.20$

$$\Rightarrow \left(\dot{m}_1/\dot{m}_2\right)_{ACT} = 0.2 \times 3.5677 = 0.7135$$

using $\dot{m}_2 = 1$ kg/s: $1.7135 \times 125.79 + \dot{m}_7 \times 83.96 = (\dot{m}_7 + 1.7135)h_5$

$$\& \ (\dot{m}_7 + 0.7135)h_5 = 0.7135 \times 2519.8 + \dot{m}_7 \times 42.01$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Solving, $\dot{m}_7 = 39.762$ & $h_5 = h_{10} = 85.69$ kJ/kg

Then, $\dot{Q}_L = 39.762(83.96 - 42.01) = 1668$ kW

$h_{11} = 85.69 + 0.47 = 86.16$ kJ/kg

$\dot{Q}_H = 1(2746.5 - 86.16) = 2660.3$ kW

& $\dot{Q}_L / \dot{Q}_H = 1668/2660.3 =$ **0.627**

9.192 a

A refrigerator with R-12 as the working fluid has a minimum temperature of −10°C and a maximum pressure of 1 MPa. Assume an ideal refrigeration cycle as in Fig. 9.23. Find the specific heat transfer from the cold space and that to the hot space, and the coefficient of performance.

Solution:

Exit evaporator sat. vapor −10°C from CATT3: $h_1 = 183.19$, $s_1 = 0.7019$ kJ/kgK

Exit condenser sat. liquid 1 MPa from CATT3: $h_3 = 76.22$ kJ/kg

Compressor: $s_2 = s_1$ & P_2 from CATT3 $\Rightarrow$ $h_2 = 210.1$ kJ/kg

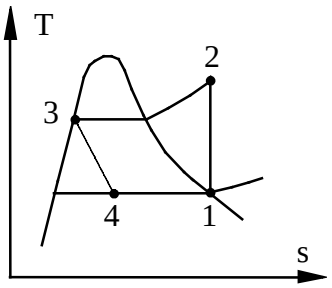
Evaporator: $q_L = h_1 - h_4 = h_1 - h_3 = 183.19 - 76.22 =$ **107 kJ/kg**

Condenser: $q_H = h_2 - h_3 = 210.1 - 76.22 =$ **133.9 kJ/kg**

COP: $\beta = q_L/w_c = q_L/(q_H - q_L) =$ **3.98**

Ideal refrigeration cycle
$P_{cond} = P_3 = P_2 = 1$ MPa
$T_{evap} = -10^oC = T_1$

Properties from CATT3



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.192 b

Consider an ideal refrigeration cycle that has a condenser temperature of 45°C and an evaporator temperature of –15°C. Determine the coefficient of performance of this refrigerator for the working fluid R-12.

Solution:

Ideal refrigeration cycle

$T_{cond} = 45^{o}C = T_3$

$T_{evap} = -15^{o}C = T_1$

	Property for:	**R-12**
Compressor	h_1, kJ/kg	180.97
	$s_2 = s_1$, kJ/kg K	0.7051
	P_2, MPa	1.0843
	T_2, ^{o}C	54.7
	h_2, kJ/kg	212.63
	$w_C = h_2 - h_1$	31.66
Exp. valve	$h_3 = h_4$, kJ/kg	79.71
Evaporator	$q_L = h_1 - h_4$	101.26
	$\beta = q_L/w_C$	**3.198**

The properties are from the computer program CATT3.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.192 c

A refrigerator in a meat warehouse must keep a low temperature of -15°C and the outside temperature is 20°C. It uses R-12 as the refrigerant which must remove 5 kW from the cold space. Find the flow rate of the R-12 needed assuming a standard vapor compression refrigeration cycle with a condenser at 20°C.

Solution:

Basic refrigeration cycle: $T_1 = T_4 = -15°C$, $T_3 = 20°C$

Computer Tables CATT3: $h_4 = h_3 = 54.87$ kJ/kg; $h_1 = h_g = 180.97$ kJ/kg

$$\dot{Q}_L = \dot{m}_{R\text{-}12} \times q_L = \dot{m}_{R\text{-}12}(h_1 - h_4)$$

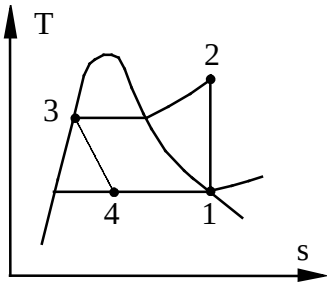
$$q_L = 180.97 - 54.87 = 126.1 \text{ kJ/kg}$$

$$\dot{m}_{R\text{-}12} = 5.0 / 126.1 = \mathbf{0.03965 \text{ kg/s}}$$

Ideal refrigeration cycle

$T_{cond} = 20^oC$

$T_{evap} = -15^oC = T_1$



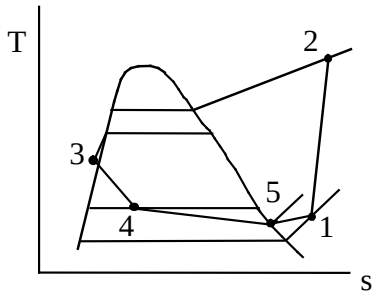
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.192 d

In an actual refrigeration cycle using R-12 as the working fluid, the refrigerant flow rate is 0.05 kg/s. Vapor enters the compressor at 150 kPa, –10°C, and leaves at 1.2 MPa, 75°C. The power input to the compressor is measured and found be 2.4 kW. The refrigerant enters the expansion valve at 1.15 MPa, 40°C, and leaves the evaporator at 175 kPa, –15°C. Determine the entropy generation in the compression process, the refrigeration capacity and the coefficient of performance for this cycle.

Solution:

Actual refrigeration cycle



1: compressor inlet $T_1 = -10^oC$, $P_1 = 150$ kPa

2: compressor exit $T_2 = 75^oC$, $P_2 = 1.2$ MPa

3: Expansion valve inlet $T_3 = 40^oC$
$P_3 = 1.15$ MPa

5: evaporator exit $T_5 = -15^oC$, $P_5 = 175$ kPa

CATT3: $h_1 = 184.8$, $s_1 = 0.7324$, $h_2 = 226.7$, $s_2 = 0.741$

CV Compressor: $h_1 + q_{COMP} + w_{COMP} = h_2$; $s_1 + \int dq/T + s_{gen} = s_2$

$w_{COMP} = \dot{W}_{COMP}/\dot{m} = 2.4/0.05 = 48.0$ kJ/kg

$q_{COMP} = h_2 - w_{COMP} - h_1 = 226.7 - 48.0 - 184.8 = -6.1$ kJ/kg

$s_{gen} = s_2 - s_1 - q / T_o = 0.741 - 0.7324 + 6.1/298.15 =$ **0.029 kJ / kg K**

C.V. Evaporator

$q_L = h_5 - h_4 = 181.5 - 74.59 = 106.9$ kJ/kg

$\Rightarrow \dot{Q}_L = \dot{m} q_L = 0.05 \times 106.9 =$ **5.346 kW**

COP: $\beta = q_L/w_{COMP} = 106.9/48.0 =$ **2.23**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.193 a

Do Problem 9.21 with R-22 as the working fluid.

A supply of geothermal hot water is to be used as the energy source in an ideal Rankine cycle, with R-134a as the cycle working fluid. Saturated vapor R-134a leaves the boiler at a temperature of 85°C, and the condenser temperature is 40°C. Calculate the thermal efficiency of this cycle.

Solution:

CV: Pump (use R-22 Computer Table in CATT3)

$$w_P = h_2 - h_1 = \int_1^2 vdP \approx v_1(P_2-P_1) = 0.000884(4037 - 1534) = 2.21 \text{ kJ/kg}$$

$$h_2 = h_1 + w_P = 94.27 + 2.21 = 96.48 \text{ kJ/kg}$$

CV: Boiler: $q_H = h_3 - h_2 = 253.69 - 96.48 = 157.21$ kJ/kg

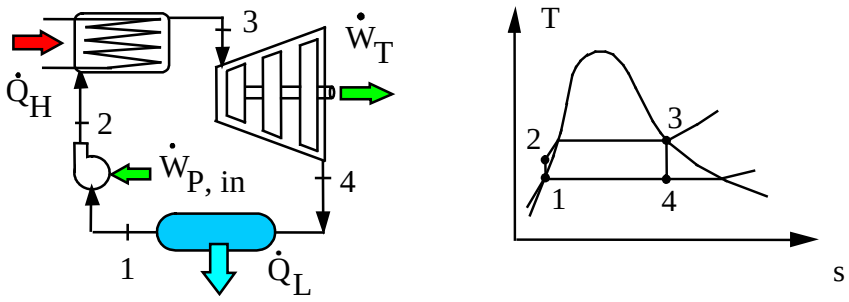
CV: Turbine

$$s_4 = s_3 = 0.7918 = 0.3417 + x_4 \times 0.5329, \quad => \quad x_4 = 0.8446$$

$$h_4 = 94.27 + 0.8446 \times 166.88 = 235.22 \text{ kJ/kg}$$

$$w_T = h_3 - h_4 = 253.69 - 235.22 = 18.47 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = (18.47 - 2.21)/157.21 = \mathbf{0.1034}$$

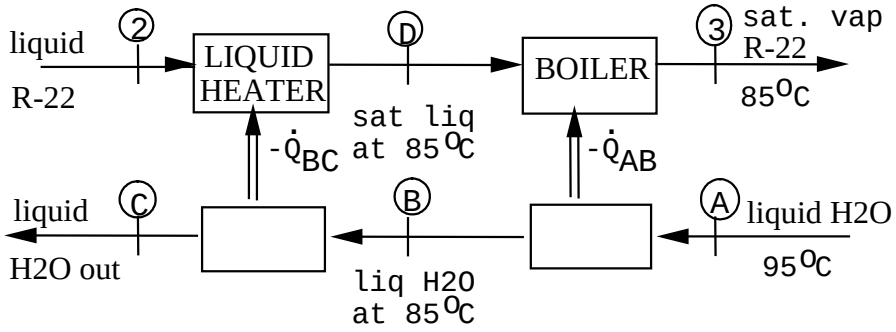


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.193 b

Do problem 9.65 with R-22 as the working fluid.

A flow with 2 kg/s of water is available at 95°C for the boiler. The restrictive factor is the boiling temperature of 85°C. Therefore, break the process up from 2-3 into two parts as shown in the diagram.



Properties from CATT3.

$$-\dot{Q}_{AB} = \dot{m}_{H2O}(h_A - h_B) = 2(397.94 - 355.88) = 84.12 \text{ kW}$$

$$= \dot{m}_{R\text{-}22}(253.69 - 165.09) \Rightarrow \dot{m}_{R\text{-}22} = 0.949 \text{ kg/s}$$

To verify that $T_D = T_3$ is the restrictive factor, find T_C.

$$-\dot{Q}_{AC} = 0.949(165.09 - 96.48) = 65.11 = 2.0(355.88 - h_C)$$

$$h_C = 323.32 \text{ kJ/kg} \Rightarrow T_C = 77.2^{\circ}\text{C} \quad \textbf{OK}$$

State 1: 40°C, 1533.5 kPa, $v_1 = 0.000884$ m^3/kg

CV Pump: $w_P = v_1(P_2 - P_1) = 0.000884(4036.8 - 1533.5) = 2.21$ kJ/kg

CV: Turbine

$$s_4 = s_3 = 0.7918 = 0.3417 + x_4 \times 0.5329 \Rightarrow x_4 = 0.8446$$

$$h_4 = 94.27 + 0.8446 \times 166.88 = 235.22 \text{ kJ/kg}$$

Energy Eq.: $w_T = h_3 - h_4 = 253.69 - 235.22 = 18.47$ kJ/kg

Cycle: $w_{NET} = w_T - w_P = 18.47 - 2.21 = 16.26$ kJ/kg

$$\dot{W}_{NET} = \dot{m}_{R22} w_{NET} = 0.949 \times 16.26 = \textbf{15.43 kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.193 c

Consider an ideal refrigeration cycle that has a condenser temperature of 45°C and an evaporator temperature of –15°C. Determine the coefficient of performance of this refrigerator for the working fluid R-22.

Solution:

Ideal refrigeration cycle

$T_{cond} = 45^{o}C = T_3$

$T_{evap} = -15^{o}C = T_1$

	Property for:	**R-22**
Compressor	h_1, kJ/kg	244.13
	$s_2 = s_1$, kJ/kg K	0.9505
	P_2, MPa	1.729
	T_2, ^{o}C	74.4
	h_2, kJ/kg	289.26
	$w_C = h_2 - h_1$	45.13
Exp. valve	$h_3 = h_4$, kJ/kg	100.98
Evaporator	$q_L = h_1 - h_4$	143.15
	$\beta = q_L/w_C$	**3.172**

The properties are from CATT3**.**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.193 SI version of d)

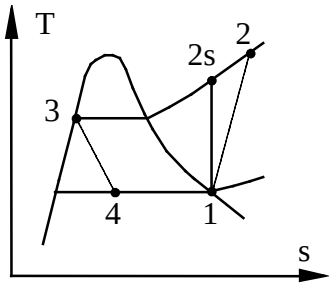
The refrigerant R-22 is used as the working fluid in a conventional heat pump cycle. Saturated vapor enters the compressor of this unit at 10°C; its exit temperature from the compressor is measured and found to be 85°C. If the compressor exit is at 2 MPa what is the compressor isentropic efficiency and the cycle COP?

Solution:

R-22 heat pump:
Computer Table

State 1: $T_{EVAP} = 10^oC$, x = 1
$h_1 = 253.42$ kJ/kg, $s_1 = 0.9129$ kJ/kg K

State 2: T_2, P_2: $h_2 = 295.17$ kJ/kg



C.V. Compressor

Energy Eq.: $w_{C\,ac} = h_2 - h_1 = 295.17 - 253.42 =$ **41.75 kJ/kg**

State 2s: 2 MPa , $s_{2S} = s_1 = 0.9129$ kJ/kg $T_{2S} = 69^oC$, $h_{2S} = 280.2$ kJ/kg

Efficiency: $$\eta = \frac{w_{C\,s}}{w_{C\,ac}} = \frac{h_{2S} - h_1}{h_2 - h_1} = \frac{280.2 - 253.42}{295.17 - 253.42} =$$ **0.6414**

C.V. Condenser

Energy Eq.: $q_H = h_2 - h_3 = 295.17 - 109.6 = 185.57$ kJ/kg

COP Heat pump: $$\beta = \frac{q_H}{w_{C\,ac}} = \frac{185.57}{41.75} =$$ **4.44**

Rankine cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.147E

A steam power plant, as shown in Fig. 9.3, operating in a Rankine cycle has saturated vapor at 600 lbf/in.^{2} leaving the boiler. The turbine exhausts to the condenser operating at 2.23 lbf/in.^{2}. Find the specific work and heat transfer in each of the ideal components and the cycle efficiency.

Solution:

For the cycle as given:

1: $h_1 = 97.97$ Btu/lbm, $v_1 = 0.01625$ ft^3/lbm,

3: $h_3 = h_g = 1204.06$ Btu/lbm, $s_3 = s_g = 1.4464$ Btu/lbm R

C.V. Pump Reversible and adiabatic.

Energy: $w_p = h_2 - h_1$; Entropy: $s_2 = s_1$

since incompressible it is easier to find work (positive in) as

$$w_P = \int v\, dP = v_1(P_2 - P_1) = 0.01625 \text{ ft}^3/\text{lbm} \times (600 - 2.2) \text{ psi} \times 144 \text{ in}^2/\text{ft}^2$$

$$= 1398.85 \text{ lbf-ft} = \mathbf{1.8 \text{ Btu/lbm}}$$

$h_2 = h_1 + w_P = 97.97 + 1.8 = 99.77$ Btu/lbm

C.V. Boiler: $q_H = h_3 - h_2 = 1204.06 - 99.77 = \mathbf{1104.3 \text{ Btu/lbm}}$

C.V. Tubine: $w_T = h_3 - h_4$, $s_4 = s_3$

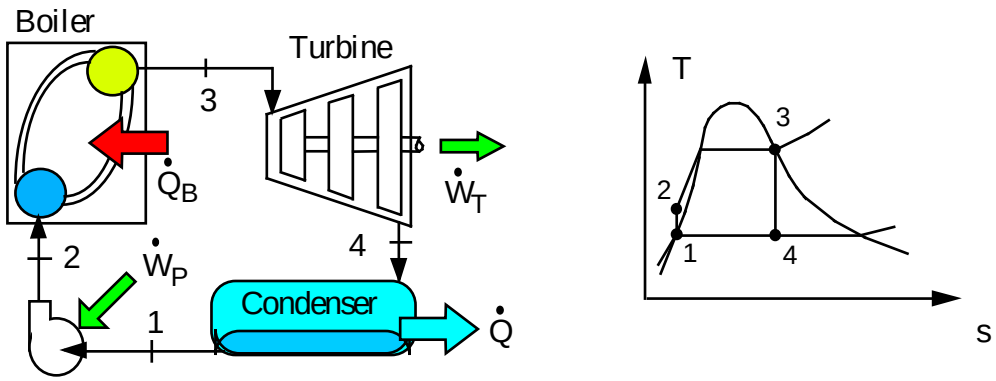
$s_4 = s_3 = 1.4464 = 0.1817 + x_4 \times 1.7292$ => $x_4 = 0.7314$,

$h_4 = 97.97 + 0.7314 \times 1019.78 = 843.84$ Btu/lbm

$w_T = 1204.06 - 843.84 = \mathbf{360.22 \text{ Btu/lbm}}$

$\eta_{CYCLE} = (w_T - w_P)/q_H = (360.22 - 1.8)/1104.3 = \mathbf{0.325}$

C.V. Condenser: $q_L = h_4 - h_1 = 843.84 - 97.97 = \mathbf{745.9 \text{ Btu/lbm}}$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.148E

Consider a solar-energy-powered ideal Rankine cycle that uses water as the working fluid. Saturated vapor leaves the solar collector at 150 psia, and the condenser pressure is 0.95 lbf/in.^{2}. Determine the thermal efficiency of this cycle.

H_2O ideal Rankine cycle

CV: turbine

State 3: Table F.7.1 $h_3 = 1194.91$ Btu/lbm, $s_3 = 1.5704$ Btu/lbm R

CV Turbine adiabatic and reversible so second law gives

$$s_4 = s_3 = 1.5704 = 0.1296 + x_4 \times 1.8526 \quad \Rightarrow \quad x_4 = 0.77772$$

$$h_4 = 68.04 + 0.77772 \times 1036.98 = 874.52 \text{ Btu/lbm}$$

The energy equation gives

$$w_T = h_3 - h_4 = 1194.91 - 874.52 = 320.39 \text{ Btu/lbm}$$

C.V. pump and incompressible liquid gives work into pump

$$w_P = \int v dP \approx v_1(P_2 - P_1) = 0.01613 \text{ ft}^3/\text{lbm} \times (150 - 0.95) \text{ psi} \times 144 \text{ in}^2/\text{ft}^2$$

$$= 346.2 \text{ lbf-ft} = 0.44 \text{ Btu/lbm}$$

$$h_2 = h_1 + w_P = 68.04 + 0.44 = 68.48 \text{ Btu/lbm}$$

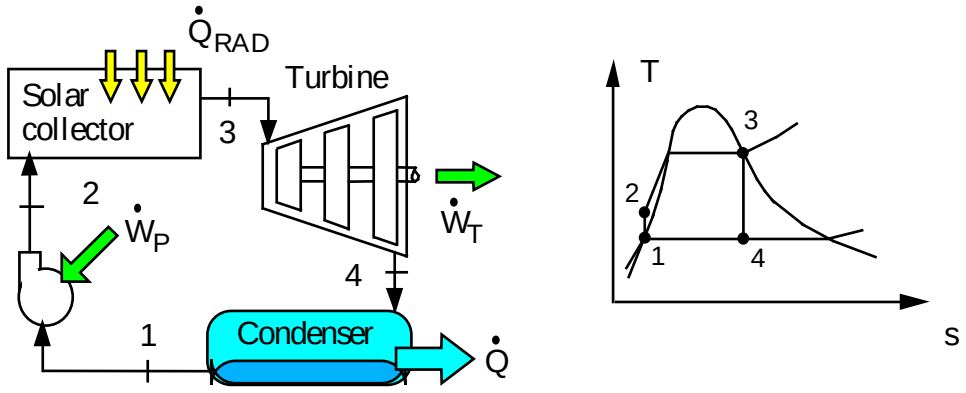
C.V. boiler gives the heat transfer from the energy equation as

$$q_H = h_3 - h_2 = 1194.91 - 68.48 = 1126.43 \text{ Btu/lbm}$$

The cycle net work and efficiency are found as

$$w_{NET} = w_T - w_P = 320.39 - 0.44 = 319.95 \text{ Btu/lbm}$$

$$\eta_{TH} = w_{NET}/q_H = 319.95/1126.43 = \mathbf{0.284}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.149E

The power plant in the previous problem is augmented with a natural gas burner to superheat the water to 600 F before entering the turbine. Find the cycle efficiency with this configuration and the specific heat transfer added by the natural gas burner.

Solution:

C.V. H_2O ideal Rankine cycle

State 3: 150 psia, 600 F, $h_3 = 1325.69$ Btu/lbm, $s_3 = 1.7110$ Btu/lbm R

CV Turbine adiabatic and reversible so second law gives

$$s_4 = s_3 = 1.7110 = 0.1296 + x_4 \times 1.8526 \quad \Rightarrow \quad x_4 = 0.85361$$

$$h_4 = 68.04 + 0.85361 \times 1036.98 = 953.22 \text{ Btu/lbm}$$

The energy equation gives

$$w_T = h_3 - h_4 = 1325.69 - 953.22 = 372.47 \text{ Btu/lbm}$$

C.V. pump and incompressible liquid gives work into pump

$$w_P = \int v dP \approx v_1(P_2 - P_1) = 0.01613 \text{ ft}^3/\text{lbm} \times (150 - 0.95) \text{ psi} \times 144 \text{ in}^2/\text{ft}^2$$

$$= 346.2 \text{ lbf-ft} = 0.44 \text{ Btu/lbm}$$

$$h_2 = h_1 + w_P = 68.04 + 0.44 = 68.48 \text{ Btu/lbm}$$

C.V. boiler gives the heat transfer from the energy equation as

$$q_H = h_3 - h_2 = 1325.69 - 68.48 = 1257.21 \text{ Btu/lbm}$$

The cycle net work and efficiency are found as

$$w_{NET} = w_T - w_P = 372.47 - 0.44 = 372.03 \text{ Btu/lbm}$$

$$\eta_{TH} = w_{NET}/q_H = 372.03/1257.21 = \mathbf{0.296}$$

9.150E

A Rankine cycle with R-410A has the boiler at 600 psia superheating to 340 F and the condenser operates at 100 psia. Find all four energy transfers and the cycle efficiency.

State 1: $v_1 = 0.01349$ ft^3/lbm, $h_1 = 21.9$ Btu/lbm (at 23.84 F)

State 3: $h_3 = 183.9$ Btu/lbm, $s_3 = 0.3091$ Btu/lbm-R

State 4: (100 psia, $s = s_3$) $h_4 = 152.0$ Btu/lbm interpolated sup. vap.

C.V. Pump: $w_P = \int v\, dP = v_1(P_2 - P_1)$

$= 0.01349$ ft^3/lbm $\times$ (600 – 100) psi $\times 144$ in^2/ft^2 = 971.3 lbf-ft

$=$ **1.25 Btu/lbm**

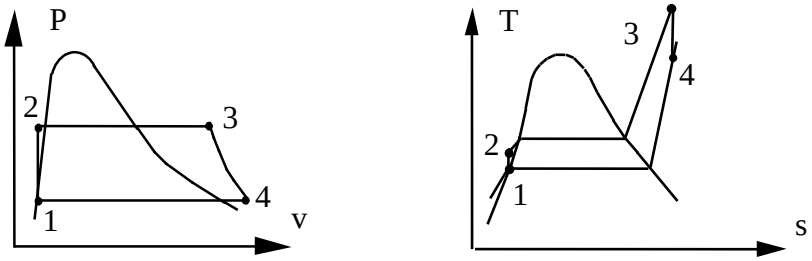
$\Rightarrow h_2 = h_1 + w_P = 21.9 + 1.25 = 23.15$ Btu/lbm

C.V. Boiler: $q_H = h_3 - h_2 = 183.9 - 23.15 =$ **160.75 Btu/lbm**

C.V. Tubine energy: $w_{T,s} = h_3 - h_4 = 183.9 - 152.0 =$ **31.9 Btu/lbm**

C.V. Condenser: $q_L = h_4 - h_1 = 152.0 - 21.9 =$ **130.1 Btu/lbm**

$$\eta_{CYCLE} = w_{NET}/q_H = \frac{31.9 - 1.25}{160.75} = \mathbf{0.191}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.151E

A supply of geothermal hot water is to be used as the energy source in an ideal Rankine cycle, with R-134a as the cycle working fluid. Saturated vapor R-134a leaves the boiler at a temperature of 180 F, and the condenser temperature is 100 F. Calculate the thermal efficiency of this cycle.

Solution:

CV: Pump (use R-134a Table F.10)

$P_1 = 138.93$ psia, $P_2 = P_3 = 400.4$ psia

$h_3 = 184.36$ Btu/lbm, $s_3 = 0.402$ Btu/lbm R

$h_1 = 108.86$ Btu/lbm, $v_1 = 0.01387$ ft^3/lbm

$$w_P = h_2 - h_1 = \int_1^2 v dP \approx v_1(P_2 - P_1)$$

$$= 0.01387(400.4 - 138.93)\frac{144}{778} = 0.671 \text{ Btu/lbm}$$

$$h_2 = h_1 + w_P = 108.86 + 0.671 = 109.53 \text{ Btu/lbm}$$

CV: Boiler

$$q_H = h_3 - h_2 = 184.36 - 109.53 = 74.83 \text{ Btu/lbm}$$

CV: Turbine

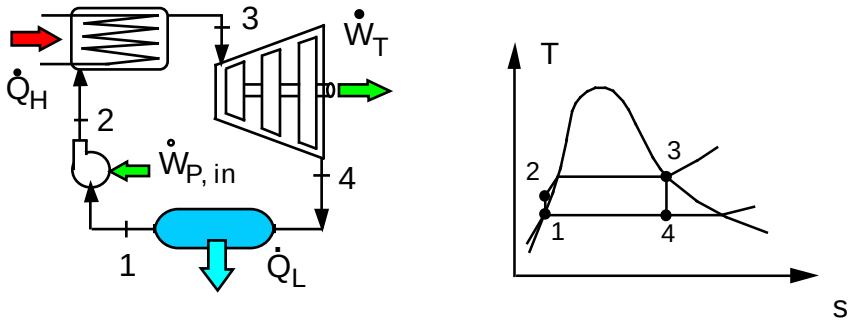
$s_4 = s_3 = 0.402 \Rightarrow x_4 = (0.402 - 0.2819)/0.1272 = 0.9442$

$h_4 = 176.08$ Btu/lbm,

Energy Eq.: $w_T = h_3 - h_4 = 8.276$ Btu/lbm

$w_{NET} = w_T - w_P = 8.276 - 0.671 = 7.605$ Btu/lbm

$\eta_{TH} = w_{NET} / q_H = 7.605/74.83 =$ **0.102**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.152E

Do Problem 9.151E with R-410A as the working fluid, boiler exit at 160 F, 600 psia.

Standard Rankine cycle with properties from the R-410A tables,

$h_1 = 51.58$ Btu/lbm, $v_1 = 0.01619$ ft^3/lbm, $P_1 = 332.54$ psia,

$P_2 = P_3 = 600$ psia, $h_3 = 125.06$ Btu/lbm, $s_3 = 0.2248$ Btu/lbm R

CV: Pump $w_P = v_1(P_2\text{-}P_1) = 0.01619\ (600 - 332.54)\ \frac{144}{778} = 0.80$ Btu/lbm

$h_2 = h_1 + w_P = 51.58 + 0.80 = 52.38$ Btu/lbm

CV: Turbine $s_4 = s_3$

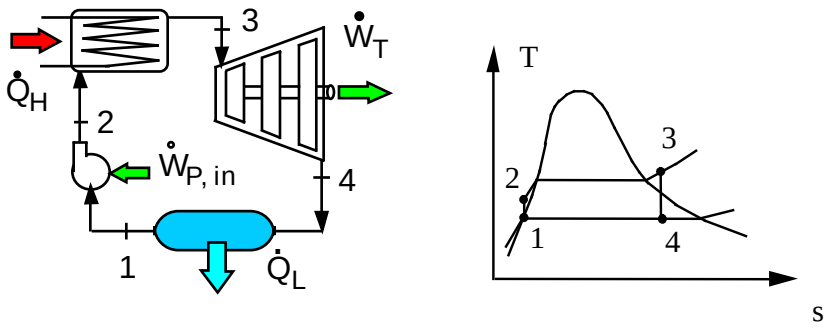
$\Rightarrow x_4 = (0.2248 - 0.1038)/0.1256 = 0.9634$

$h_4 = 119.32$ Btu/lbm, $w_T = h_3 - h_4 = 5.74$ Btu/lbm

CV: Boiler

$q_H = h_3 - h_2 = 125.06 - 52.38 = 72.68$ Btu/lbm

$\eta_{TH} = (w_T - w_P)/q_H = (5.74 - 0.80)/72.68 =$ **0.068**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.153E

A low temperature power plant operates with R-410A maintaining 60 psia in the condenser, a high pressure of 400 psia with superheat. Find the temperature out of the boiler/superheater so the turbine exit temperature is 20 F and find the overall cycle efficiency.

State 1: $P_1 = 60$ psia, $v_1 = 0.0129$ ft^3/lbm, $h_1 = 12.7$ Btu/lbm

State 4: $P_4 = P_1 = 60$ psia, $h_4 = 343.58$ Btu/lbm, $s_4 = 1.3242$ Btu/lbm-R

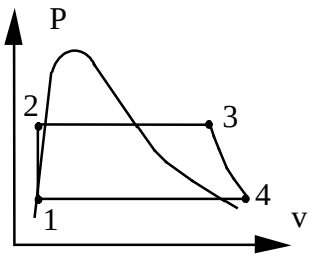
State 3: 400 psia, $s = s_4$ ⇨ $h_3 = 147.2$ Btu/lbm, $T_3 =$ **190.3 F**

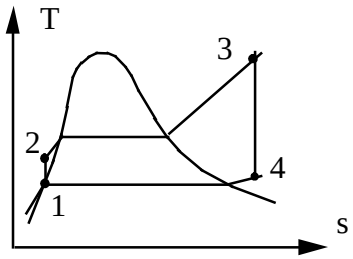
Pump: $w_P = v_1 (P_2 - P_1) = 0.0129 (400 - 60) \frac{144}{778} = 2.09$ Btu/lbm

Boiler: $q_H = h_3 - h_2 = 426.56 - (12.7 + 0.8) = 133.7$ Btu/lbm

Turbine: $w_T = h_3 - h_4 = 147.2 - 122.1 = 25.1$ Btu/lbm

Efficiency: $\eta_{TH} = w_{NET}/q_H = (w_T - w_P)/q_H = \frac{25.1 - 0.8}{133.7} =$ **0.182**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.154E

A smaller power plant produces 50 lbm/s steam at 400 psia, 1100 F, in the boiler. It cools the condenser with ocean water coming in at 60 F and returned at 65 F so that the condenser exit is at 110 F. Find the net power output and the required mass flow rate of the ocean water.

Solution:

The states properties from Tables F.7.1 and F.7.2

1: 110 F, x = 0: h_1 = 78.01 Btu/lbm, v_1 = 0.01617 ft^3/lbm, P_{sat} = 1.28 psia

3: 400 psia, 1100 F: h_3 = 1577.44 Btu/lbm, s_3 = 1.7989 Btu/lbm R

C.V. Pump Reversible and adiabatic.

Energy: $w_p = h_2 - h_1$; Entropy: $s_2 = s_1$

since incompressible it is easier to find work (positive in) as

$$w_p = \int v\, dP = v_1 (P_2 - P_1) = 0.01617\ (400 - 1.3)\frac{144}{778} = 1.19 \text{ Btu/lbm}$$

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$

$$s_4 = s_3 = 1.7989 = 0.1473 + x_4\ (1.8101) \quad \Rightarrow \quad x_4 = 0.9124$$

$$\Rightarrow\ h_4 = 78.01 + 0.9124\ (1031.28) = 1018.95 \text{ Btu/lbm}$$

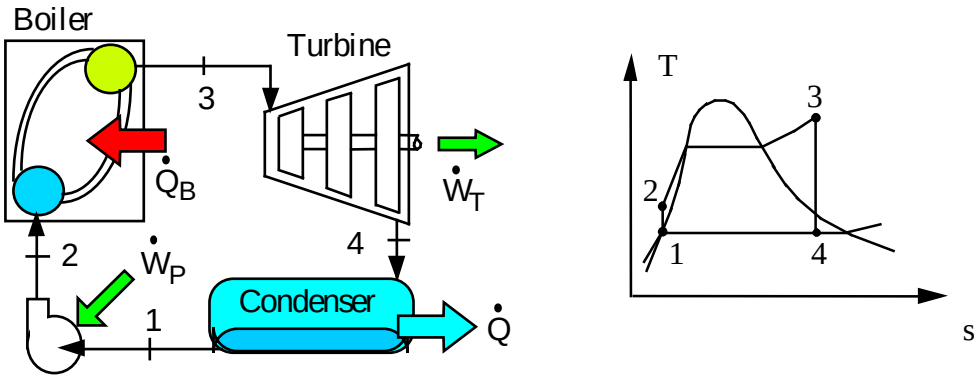
$$w_T = 1577.44 - 1018.95 = 558.5 \text{ Btu/lbm}$$

$$\dot{W}_{NET} = \dot{m}(w_T - w_p) = 50\ (558.5 - 1.19) = \mathbf{27\ 866\ Btu/s}$$

C.V. Condenser : $q_L = h_4 - h_1 = 1018.95 - 78.01 = 940.94$ Btu/lbm

$$\dot{Q}_L = \dot{m} q_L = 50 \times 940.94 = 47\ 047 \text{ Btu/s} = \dot{m}_{ocean}\, C_p\, \Delta T$$

$$\dot{m}_{ocean} = \dot{Q}_L / C_p\, \Delta T = 47\ 047 / (1.0 \times 5) = \mathbf{9409\ lbm/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.155E

Consider a simple ideal Rankine cycle using water at a supercritical pressure. Such a cycle has a potential advantage of minimizing local temperature differences between the fluids in the steam generator, such as the instance in which the high-temperature energy source is the hot exhaust gas from a gas-turbine engine. Calculate the thermal efficiency of the cycle if the state entering the turbine is 8000 lbf/in.^{2}, 1300 F, and the condenser pressure is 0.95 lbf/in.^{2}. What is the steam quality at the turbine exit?

Solution:

For the efficiency we need the net work and steam generator heat transfer.

State 1: $s_1 = 0.1296$ Btu/lbm R, $h_1 = 68.04$ Btu/lbm

State 3: $h_3 = 1547.5$ Btu/lbm, $s_3 = 1.4718$ Btu/lbm R

C.V. Pump. For this high exit pressure we use Table F.7.3 to get state 2.

Entropy Eq.: $s_2 = s_1 \quad => \quad h_2 = 91.69$ Btu/lbm

$w_p = h_2 - h_1 = 91.69 - 68.04 = 23.65$ Btu/lbm

C.V. Turbine. Assume reversible and adiabatic.

Entropy Eq.: $s_4 = s_3 = 1.4718 = 0.1296 + x_4 \times 1.8526$

$x_4 =$ **0.7245** Very low for a turbine exhaust

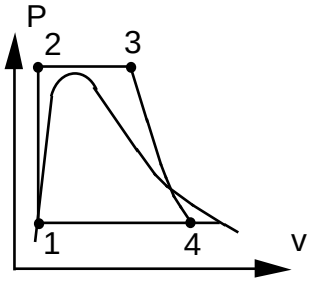
$h_4 = 68.04 + x_4 \times 1036.98 = 751.29$ Btu/lbm,

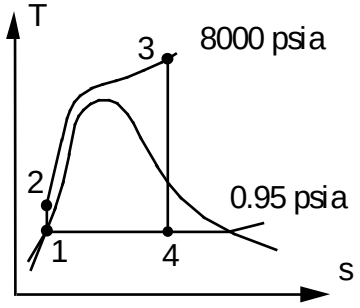
$w_T = h_3 - h_4 = 796.2$ Btu/lbm

Steam generator: $q_H = h_3 - h_2 = 1547.5 - 91.69 = 1455.8$ Btu/lbm

$w_{NET} = w_T - w_p = 796.2 - 23.65 = 772.6$ Btu/lbm

$\eta = w_{NET}/q_H = 772.6 / 1455.8 =$ **0.53**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.156E

A Rankine cycle uses ammonia as the working substance and powered by solar energy. It heats the ammonia to 320 F at 800 psia in the boiler/superheater. The condenser is water cooled, and the exit is kept at 70 F. Find (T, P, and x if applicable) for all four states in the cycle.

NH_3 ideal Rankine cycle

State 1: Table F.8.1, T = 70 F, x = 0, P_1 = 128.85 psia,

h_1 = 120.21 Btu/lbm, v_1 = 0.2631 ft^3/lbm

CV Pump:

$w_P = h_2 - h_1 \approx v_1(P_2 - P_1)$ = 0.02631 ft^3/lbm (800 – 128.85) psi ×144 in^2/ft^2

= 2542.75 lbf-ft = 3.27 Btu/lbm

$h_2 = h_1 + w_P$ = 120.21 + 3.27 = 123.48 Btu/lbm $\approx h_f + (P_2 - P_{sat})v_f$

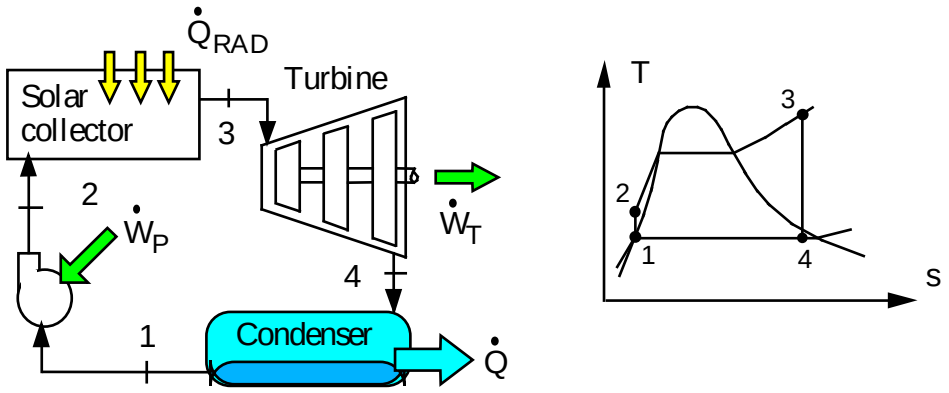
=> $T_2 \approx T_1$ = 70 F [with the CATT3 we do (P_2, $s_2 = s_1$)]

State 3: 320 F, 800 psia : superheated vapor, s_3 = 1.1915 Btu/lbm

CV: turbine

$s_4 = s_3$ = 1.1915 = 0.2529 + x_4 × 0.9589 => x_4 = 0.9788

$P_4 = P_1$ = 128.85 psia, $T_4 = T_1$ = 70 F



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.157E

Assume the powerplant in Problem 9.156E should deliver 1000 Btu/s. What is the mass flow rate of ammonia?

State 3: 320 F, 800 psia: $h_3 = 734.7$ Btu/lbm, $s_3 = 1.1915$ Btu/lbm

CV: turbine

Energy: $w_{T,s} = h_3 - h_4$; Entropy: $0 = s_3 - s_4 + 0$

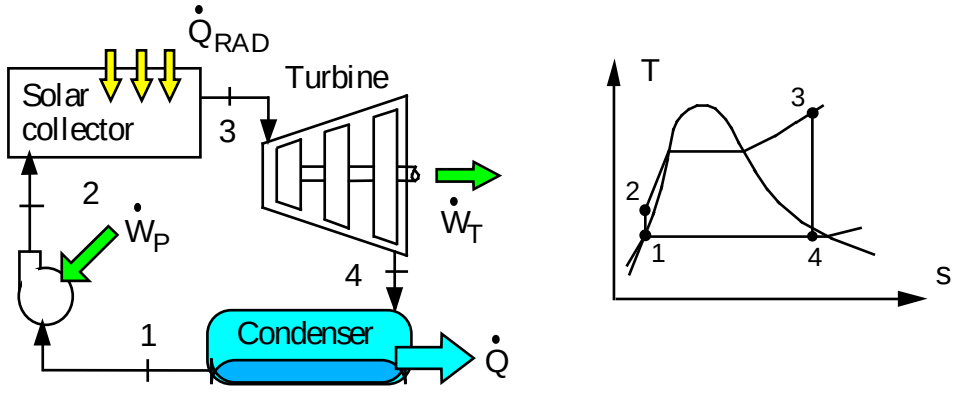
$s_4 = s_3 = 1.1915 = 0.2529 + x_4 \times 0.9589$ => $x_4 = 0.9788$

$h_4 = 120.21 + 0.9788\ 507.89 = 617.3$ Btu/lbm

$w_{T,s} = h_3 - h_4 = 734.7 - 617.3 = 117.4$ Btu/lbm

$\dot{W}_T = \dot{m}\, w_{T,s}$;

$$\dot{m} = \dot{W}_T / w_{T,s} = \frac{1000 \text{ Btu/s}}{117.4 \text{ Btu/lbm}} = \mathbf{8.518\ lbm/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.158E

Consider an ideal steam reheat cycle in which the steam enters the high-pressure turbine at 600 lbf/in.^{2}, 700 F, and then expands to 150 lbf/in.^{2}. It is then reheated to 700 F and expands to 2.225 lbf/in.^{2} in the low-pressure turbine. Calculate the thermal efficiency of the cycle and the moisture content of the steam leaving the low-pressure turbine.

Solution:

Basic Rankine cycle with a reheat section. For this cycle from Table F.7

State 3: Superheated vapor $h_3 = 1350.62$ Btu/lbm, $s_3 = 1.5871$ Btu/lbm R,

State 1: Saturated liquid $h_1 = 97.97$ Btu/lbm, $v_1 = 0.01625$ ft^3/lbm

C.V. Pump: Adiabatic and reversible. Use incompressible fluid so

$$w_P = \int v\, dP = v_1(P_2 - P_1) = 0.01625(600 - 2.2)\frac{144}{778} = 1.8 \text{ Btu/lbm}$$

$$h_2 = h_1 + w_P = 97.97 + 1.8 = 99.77 \text{ Btu/lbm}$$

C.V. HP Tubine section: $w_{T1} = h_3 - h_4$, $s_4 = s_3$ => $h_4 = 1208.93$ Btu/lbm

$$w_{T1} = 1350.62 - 1208.93 = 141.69 \text{ Btu/lbm}$$

C.V. LP Tubine section: $w_{T2} = h_5 - h_6$, $s_6 = s_5$

State 5: $h_5 = 1376.55$ Btu/lbm, $s_5 = 1.7568$ Btu/lbm R

State 6: $s_6 = s_5 = 1.7568 = 0.1817 + x_6 \times 1.7292$ => $x_6 = 0.9109$

$$h_6 = 97.97 + 0.9109 \times 1019.78 = 1026.89 \text{ Btu/lbm}$$

$$w_{T2} = 1376.55 - 1026.89 = 349.66 \text{ Btu/lbm}$$

C.V. Boiler: $q_{H1} = h_3 - h_2 = 1350.62 - 99.77 = 1250.85$ Btu/lbm

Total cycle

$$q_H = q_{H1} + h_5 - h_4 = 1250.85 + 1376.55 - 1208.93 = 1418.5 \text{ Btu/lbm}$$

$$w_{T,tot} = w_{T1} + w_{T2} = 141.69 + 349.66 = 491.35 \text{ Btu/lbm}$$

Overall efficiency

$$\eta_{CYCLE} = (w_{T,tot} - w_P)/q_H = (491.35 - 1.8)/1420.3 = \mathbf{0.345}$$

9.159E

An open FWH receives steam at 150 psia, 400 F from the turbine and 150 psia, 200 F water from the feed water line. Find the required fraction of the extraction flow in the turbine.

The setup follows Fig.9.12

State enthalpies: $h_2 = 168.07$, $h_6 = 1219.51$ all Btu/lbm

$h_3 = 330.74$ (x = 0 at 150 psia, 358.47 F)

Analyze the FWH which leads to Eq.9.5:

$y = \dot{m}_6 / \dot{m}_5$ the extraction fraction

$$y = \frac{h_3 - h_2}{h_6 - h_2} = \frac{330.74 - 168.07}{1219.51 - 168.07} = \mathbf{0.1547}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.160E

Consider an ideal steam regenerative cycle in which steam enters the turbine at 600 lbf/in.^{2}, 700 F, and exhausts to the condenser at 2.225 lbf/in.^{2}. Steam is extracted from the turbine at 150 lbf/in.^{2} for an open feedwater heater. The feedwater leaves the heater as saturated liquid. The appropriate pumps are used for the water leaving the condenser and the feedwater heater. Calculate the thermal efficiency of the cycle and the net work per pound-mass of steam.

From Table F.7.2

h_5 = 1350.62 Btu/lbm,

s_5 = 1.5871 Btu/lbm R

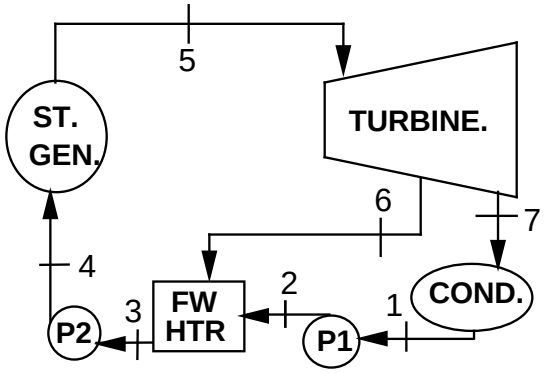
h_1 = 97.97 Btu/lbm,

v_1 = 0.01625 ft^3/lbm

Interpolate to get

h_3 = 330.67 Btu/lbm,

v_3 = 0.01809 ft^3/lbm

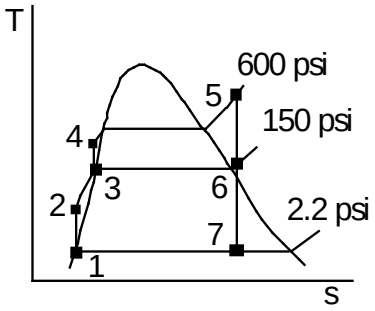


C.V. Pump1:

$$w_{P12} = 0.01625(150 - 2.2)\frac{144}{778}$$

$$= 0.44 \text{ Btu/lbm} = h_2 - h_1$$

$$h_2 = h_1 + w_{P12} = 98.41 \text{ Btu/lbm}$$



C.V. Pump2:

$$w_{P34} = 0.01809(600 - 150)144/778 = 1.507 \text{ Btu/lbm}$$

$$\Rightarrow \quad h_4 = h_3 + w_{P34} = 332.18 \text{ Btu/lbm}$$

C.V. Turbine (high pressure section)

Entropy Eq.: $s_6 = s_5 = 1.5871$ Btu/lbm R => $h_6 = 1208.93$ Btu/lbm

CV: feedwater heater, call the extraction fraction $y = \dot{m}_6/\dot{m}_3$

Continuity Eq.: $\dot{m}_3 = \dot{m}_6 + \dot{m}_2$, Energy Eq.: $\dot{m}_6 h_6 + \dot{m}_2 h_2 = \dot{m}_3 h_3$

$$yh_6 + (1 - y)h_2 = h_3 \quad \Rightarrow \quad y_6 = (h_3 - h_2)/(h_6 - h_2)$$

$$\Rightarrow \quad y = (330.67 - 98.41)/(1208.93 - 98.41) = 0.2091$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

CV: Turbine from 5 to 7

$$s_7 = s_5 \quad \Rightarrow \quad x_7 = (1.5871 - 0.1817)/1.7292 = 0.8127$$

$$h_7 = 97.97 + 0.8127 \times 1019.78 = 926.75 \text{ Btu/lbm}$$

The HP turbine section has the full flow, the LP section has fraction (1-y)

$$w_T = (h_5 - h_6) + (1 - y)(h_6 - h_7)$$

$$= (1350.62 - 1208.93) + 0.7909(1208.93 - 926.75) = 364.87 \text{ Btu/lbm}$$

CV: pumps

P2 has the full flow and P1 has the fraction 1- y of the flow

$$w_P = (1 - y)w_{P12} + w_{P34} = 0.7909 \times 0.44 + 1 \times 1.507 = 1.855 \text{ Btu/lbm}$$

$$w_{NET} = w_T - w_P = 364.87 - 1.855 = \mathbf{363.0\ Btu/lbm}$$

CV: steam generator

$$q_H = h_5 - h_4 = 1350.62 - 332.18 = 1018.44 \text{ Btu/lbm}$$

$$\eta_{TH} = w_{NET}/q_H = 363/1018.44 = \mathbf{0.356}$$

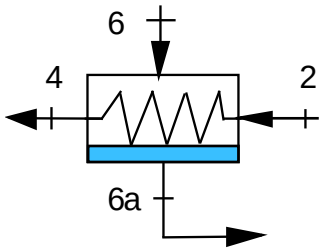
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.161E

A closed feedwater heater in a regenerative steam power cycle heats 40 lbm/s of water from 200 F, 2000 lbf/in.^{2} to 450 F, 2000 lbf/in.^{2}. The extraction steam from the turbine enters the heater at 600 lbf/in.^{2}, 550 F and leaves as saturated liquid. What is the required mass flow rate of the extraction steam?

Solution:

The schematic from Figure 9.13 has the feedwater from the pump coming at state 2 being heated by the extraction flow coming from the turbine state 6 so the feedwater leaves as saturated liquid state 4 and the extraction flow leaves as condensate state 6a.



From the steam tables F.7:

F.7.3: $h_2 = 172.6$ Btu/lbm

F.7.3: $h_4 = 431.13$ Btu/lbm

F.7.2: $h_6 = 1255.36$ Btu/lbm

Interpolate for this state

F.7.1: $h_{6a} = 471.56$ Btu/lbm

C.V. Feedwater Heater

Energy Eq.: $\dot{m}_2 h_2 + \dot{m}_6 h_6 = \dot{m}_2 h_4 + \dot{m}_6 h_{6a}$

Since all four state are known we can solve for the extraction flow rate

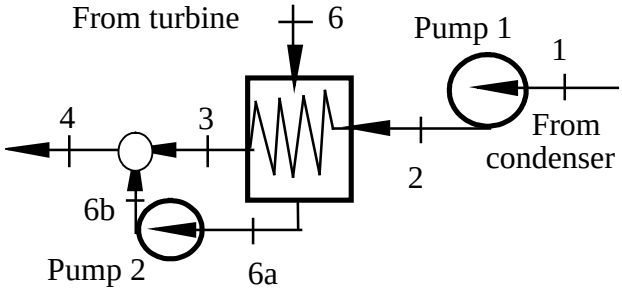
$$\dot{m}_6 = \dot{m}_2 \frac{h_2 - h_4}{h_{6a} - h_6} = 40 \text{ lbm/s} \frac{172.6 - 431.13}{471.56 - 1255.36} = \mathbf{13.2} \frac{\mathbf{lbm}}{\mathbf{s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.162E

A Rankine cycle feeds 10 lbm/s ammonia at 300 psia, 280 F to the turbine, which has an extraction point at 125 psia. The condenser is at 0 F, and a closed feed water heater has an exit state (3) at the temperature of the condensing extraction flow and it has a drip pump. The source for the boiler is at constant 350 F. Find the extraction flow rate and state 4 into the boiler.

P_1 = 30.415 psia,
h_1 = 42.6 Btu/lbm
v_1 = 0.0242 ft^3/lbm,
s_5 = 1.3062 Btu/lbm-R,
h_5 = 744.07 Btu/lbm
$T_{6a} = T_{sat\ 125\ psia}$ = 68.28 F
=> h_{6a} = 118.25 Btu/lbm



C.V. Turbine: Reversible, adiabatic so constant s from inlet to extraction point

$s_6 = s_5$ = 1.3062 Btu/lbm-R => T_6 = 148.1 F, h_6 = 679.8 Btu/lbm

C.V. P1: $w_{P1} = v_1(P_2 - P_1)$ = 0.0242(300 – 30.415) 144/778 = 1.21 Btu/lbm

$\Rightarrow$ $h_2 = h_1 + w_{P1}$ = 43.81 Btu/lbm

C.V. P2: $w_{P2} = v_{6a}(P_4 - P_6)$ = 0.02625 (300 – 125)144/778 = 0.85 Btu/lbm

$\Rightarrow$ $h_{6b} = h_{6a} + w_{P2}$ = 119.1 Btu/lbm

C.V. Total FWH and pump (notice $h_3 = h_{6a} + \Delta Pv = h_{6b}$, no table for this state)

State 3: $h_3 = h_f + (P_3 - P_{sat})v_f$ = 118.25 + 0.02625 (300–125) 144/778 = 119.1 Btu/lbm

The extraction fraction is: $y = \dot{m}_6/\dot{m}_4$

Energy: $(1 - y)h_2 + yh_6 = (1 - y)h_3 + yh_{6a}$

$$y = \frac{h_3 - h_2}{h_3 - h_2 + h_6 - h_{6a}} = \frac{119.1 - 43.81}{119.1 - 43.81 + 679.8 - 118.25} = 0.1182$$

$$\dot{m}_6 = y\,\dot{m}_4 = 0.1182 \times 10 = \mathbf{1.182\ lbm/s}$$

C.V. The junction after FWH and pump 2.

$$h_4 = (1-y)h_3 + y\,h_{6b} = (1- 0.1182) \times 119.1 + 0.1182 \times 119.1 = \mathbf{119.1\ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.163E

Do the previous problem with a closed FWH that has a trap and drain to the condenser for the extraction flow.

State 1: $x_1 = 0$, $h_1 = 42.6$ Btu/lbm, $v_1 = 0.0242$ ft^3/lbm

State 3: $h_3 = h_f + (P_3 - P_{sat})v_f = 118.25 + 0.02625\ (300 - 125)\ 144/778 = 119.1$ Btu/lbm

State 5: $h_5 = 744.07$ Btu/lbm, $s_5 = 1.3062$ Btu/lbm-R

State 6: $s_6 = s_5$ => $h_6 = 679.83$ Btu/lbm

State 6a: $x_{6a} = 0$ => $h_{6a} = 118.25$ Btu/lbm

C.V. P1: $w_{P1} = v_1(P_2 - P_1) = 0.0242(300 - 30.415)\ 144/778 = 1.21$ Btu/lbm

$\Rightarrow$ $h_2 = h_1 + w_{P1} = 43.81$ Btu/lbm

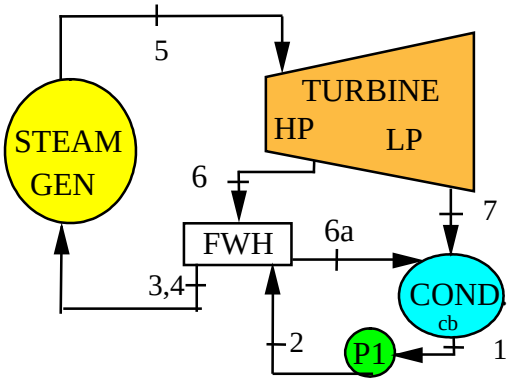
C.V. Feedwater heater: Call $\dot{m}_6 / \dot{m}_{tot} = y$ (the extraction fraction)

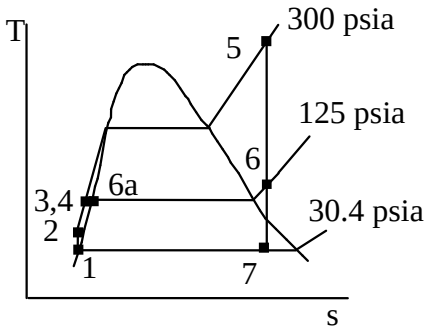
Energy Eq.: $h_2 + y\, h_6 = 1\, h_3 + y\, h_{6a}$

$$y = \frac{h_3 - h_2}{h_6 - h_{6a}} = \frac{119.1 - 43.81}{679.83 - 118.25} = 0.1341$$

$\dot{m}_{extr} = y\, \dot{m}_{tot} = 0.1341 \times 10 =$ **1.341 lbm/s**

$h_4 = h_3 =$ **119.1 Btu/lbm**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.164E

The steam power cycle in Problem 9.147E has an isentropic efficiency of the turbine of 85% and that for the pump it is 80%. Find the cycle efficiency and the specific work and heat transfer in the components.

States numbered as in fig 9.3 of text.

CV Pump: $w_{P,S} = v_1(P_2 - P_1) = 0.01625(600 - 2.2)144/778 = 1.8$ Btu/lbm

$$\Rightarrow w_{P,AC} = 1.8/0.8 = \mathbf{2.245\ Btu/lbm}$$

$$h_2 = h_1 + w_{P,AC} = 97.97 + 2.245 = 100.2 \text{ Btu/lbm}$$

CV Turbine: $w_{T,S} = h_3 - h_{4s}$, $s_4 = s_3 = 1.4464$ Btu/lbm R

$$s_4 = s_3 = 1.4464 = 0.1817 + x_4 \times 1.7292 \quad => \quad x_4 = 0.7314,$$

$$h_4 = 97.97 + 0.7314 \times 1019.78 = 843.84 \text{ Btu/lbm}$$

$$\Rightarrow w_{T,S} = 1204.06 - 843.84 = 360.22 \text{ Btu/lbm}$$

$$w_{T,AC} = h_3 - h_{4AC} = 360.22 \times 0.85 = \mathbf{306.2}$$

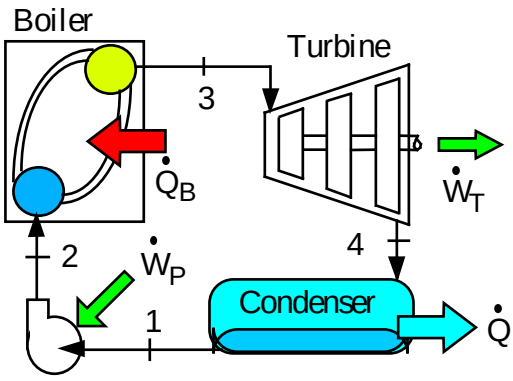
$$\Rightarrow h_{4AC} = 897.86 \text{ Btu/lbm (still two-phase)}$$

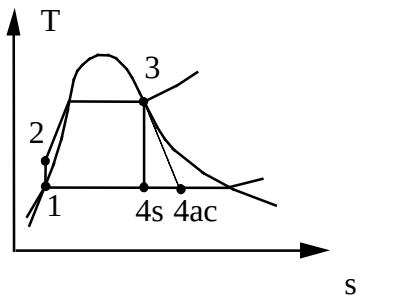
CV Boiler: $q_H = h_3 - h_2 = 1204.06 - 100.2 = \mathbf{1103.9\ Btu/lbm}$

$$q_L = h_{4AC} - h_1 = 897.86 - 97.97 = \mathbf{799.9\ Btu/lbm}$$

$$\eta_{CYCLE} = (w_T - w_P)/q_H = (306.2 - 2.245)/1103.9 = \mathbf{0.275}$$

Compared to (360.22-1.8)/1104.3 = 0.325 in the ideal case.





state 2s and 2ac nearly the same

9.165E

A **concentrated solar power** plant receives the energy from molten salt coming in at 1000 F and leaving at 600 F in a counterflow heat exchanger where the water comes in at 400 psia, 140 F and leaves at 800 F, 400 psia. The molten salt has 10 lbm/s flow with Cp = 0.36 Btu/lbm-R. What is the possible water flow rate, the rate of energy transfer and rate of entropy generation.

Continuity Eqs.: Each line has a constant flow rate through it.

Energy Eq.4.10: $0 = \dot{m}_{H_2O} (h_1 - h_2) + \dot{m}_{salt} (h_3 - h_4)$

Entropy Eq.7.7: $0 = \dot{m}_{H_2O} (s_1 - s_2) + \dot{m}_{salt} (s_3 - s_4) + \dot{S}_{gen}$

Process: Each line has a constant pressure.

Table F.7: $h_2 = 1416.59$ Btu/lbm, $s_1 = 0.1985$, $s_2 = 1.6844$ Btu/lbm-R

$h_1 = h_f + (P_3 - P_{sat})v_f = 107.96 + (400 - 2.9)\ 0.01629 \times 144/778 = 109.15$ Btu/lbm

From the energy leaving the salt we get

$$\dot{Q} = \dot{m}_{salt} (h_3 - h_4) = \dot{m}_{salt} C_{P\ salt} (T_3 - T_4)$$

$$= 10 \times 0.36\ [1000 - 600] = \mathbf{1440\ Btu/s}$$

$$\dot{m}_{H_2O} = \dot{m}_{salt} \frac{h_3 - h_4}{h_2 - h_1} = \frac{\dot{Q}}{h_2 - h_1} = \frac{1440\ \text{Btu/s}}{(1416.59 - 109.15)\ \text{Btu/lbm}} = \mathbf{1.1\ lbm/s}$$

$$s_4 - s_3 = C_{P\ salt} \ln (T_4/T_3) = 0.36 \ln(1059.7/1459.7) = -0.115\ \text{Btu/lbm-R}$$

$$\dot{S}_{gen} = \dot{m}_{H_2O} (s_2 - s_1) + \dot{m}_{salt} (s_4 - s_3)$$

$$= 1.1\ \text{lbm/s}\ (1.6844 - 0.1985) \frac{\text{Btu}}{\text{lbm-R}} - 10\ \text{lbm/s} \times 0.115 \frac{\text{Btu}}{\text{lbm-R}}$$

$$= \mathbf{0.48\ Btu/s\text{-}R}$$

C.V. Heat exchanger, steady flow 1 inlet and 1 exit for salt and water each. The two flows exchange energy with no heat transfer to/from the outside.

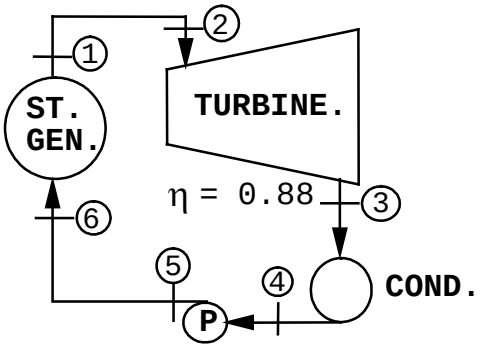
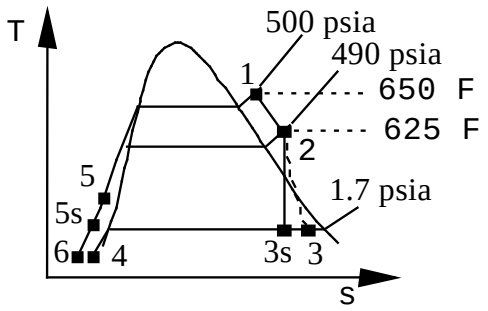
9.166E

Steam leaves a power plant steam generator at 500 lbf/in.^{2}, 650 F, and enters the turbine at 490 lbf/in.^{2}, 625 F (h = 1314 Btu/lbm, s = 1.5752 Btu/lbm-R). The isentropic turbine efficiency is 88%, and the turbine exhaust pressure is 1.7 lbf/in.^{2}. Condensate leaves the condenser and enters the pump at 110 F, 1.7 lbf/in.^{2}. The isentropic pump efficiency is 80%, and the discharge pressure is 520 lbf/in.^{2}. The feedwater enters the steam generator at 510 lbf/in.^{2}, 100 F (h = 68.1 Btu/lbm). Calculate the thermal efficiency of the cycle and the entropy generation of the flow in the line between the steam generator exit and the turbine inlet, assuming an ambient temperature of 77 F.





h_1 = 1328 Btu/lbm, s_1 = 1.562 Btu/lbm-R

$s_{3S} = s_2 = 1.5752 = 0.16483 + x_{3S} \times 1.7686$ => $x_{3S} = 0.79745$

$h_{3S} = 88.1 + 0.797\,45 \times 1025.4 = 905.8$ Btu/lbm

$w_{T,s} = h_2 - h_{3S} = 1314.0 - 905.8 = 408.2$ Btu/lbm

$w_{T,ac} = \eta_{T,s}\, w_{T,s} = 0.88 \times 408.2 = 359.2$ Btu/lbm

$h_3 = h_2 - w_{T,ac} = 1314.0 - 359.2 = 954.8$ Btu/lbm

$w_{P,s} = 0.016166\ (520 - 1.7)\ 144/778 = 1.55$ Btu/lbm

$w_{P,ac} = w_{P,s}/\eta_{P,s} = 1.55/0.80 = 1.94$ Btu/lbm

$q_H = h_1 - h_6 = 1328.0 - 68.1 = 1259.9$ Btu/lbm

$\eta_{TH} = w_{NET}/q_H = (359.2 - 1.94)/1259.9 =$ **0.284**

C.V. Line from 1 to 2: $w = \emptyset$,

Energy Eq.: $q = h_2 - h_1 = 1314 - 1328 = -14$ Btu/lbm

Entropy Eq.: $s_1 + s_{gen} + q/T_0 = s_2$ =>

$s_{gen} = s_2 - s_1 - q/T_0 = 1.5752 - 1.586 - (-14/536.7) =$ **0.0153 Btu/lbm R**

9.167E

A boiler delivers steam at 1500 lbf/in.^{2}, 1000 F to a reversible two-stage turbine as shown in Fig. 9.19. After the first stage, 25% of the steam is extracted at 200 lbf/in.^{2} for a process application and returned at 150 lbf/in.^{2}, 190 F to the feedwater line. The remainder of the steam continues through the low-pressure turbine stage, which exhausts to the condenser at 2.225 lbf/in.^{2}. One pump brings the feedwater to 150 lbf/in.^{2} and a second pump brings it to 1500 lbf/in.^{2}. If the process application requires 5000 Btu/s of power, how much power can then be cogenerated by the turbine?

C.V. Turbine T1

5: $h_5 = 1490.32$, $s_5 = 1.6001$ Btu/lbmR

6: Rev and adiabatic $s_6 = s_5 \Rightarrow$

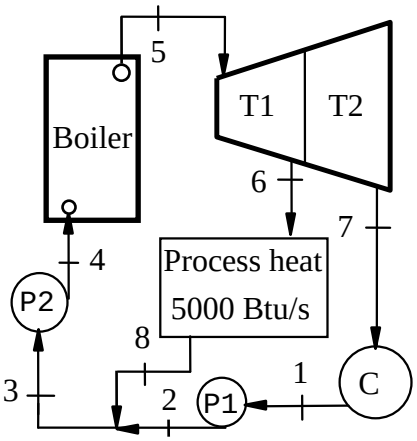
Table F.7.2 Sup. vapor

$h_6 = 1246.6$ Btu/lbm

$w_{T1} = h_5 - h_6 = 243.7$ Btu/lbm

State 7: $s_7 = s_6 = s_5 \Rightarrow$

$$x_7 = \frac{1.6001 - 0.1817}{1.7292} = 0.82026$$



$h_7 = 97.97 + 0.82026 \times 1019.78 = 934.45$ Btu/lbm

$w_{T2} = h_6 - h_7 = 1246.6 - 934.45 = 312.1$ Btu/lbm

8: Compressed liquid use sat. liq. same T: $h_8 = 158.02$ Btu/lbm;

C.V. process unit. Assume no work only heat out.

$q_{PROC} = h_6 - h_8 = 1246.6 - 158.02 = 1088.6$ Btu/lbm

$\dot{m}_6 = \dot{Q}/q_{PROC} = 5000$ Btu/s /1088.6 Btu/lbm = 4.593 lbm/s = 0.25 $\dot{m}_{TOT}$

$\Rightarrow \dot{m}_{TOT} = \dot{m}_5 = 18.372$ lbm/s, $\dot{m}_7 = \dot{m}_5 - \dot{m}_6 = 13.779$ lbm/s

C.V. Total turbine

$$\dot{W}_T = \dot{m}_5 h_5 - \dot{m}_6 h_6 - \dot{m}_7 h_7$$

$$= 18.372 \times 1490.32 - 4.593 \times 1246.6 - 13.779 \times 934.45 \left[\frac{\text{lbm}}{\text{s}} \frac{\text{Btu}}{\text{lbm}} \right]$$

$$= \mathbf{8779\ Btu/s}$$

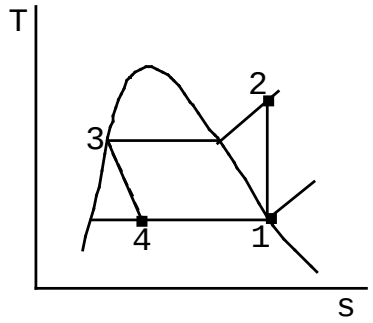
9.168E

A car air-conditioner (refrigerator) in 70 F ambient uses R-134a and I want to have cold air at 20 F produced. What is the minimum high P and the maximum low P it can use?

Since the R-134a must give heat transfer out to the ambient at 70 F, it must at least be that hot at state 3.

Ideal Ref. Cycle
T_{cond} = 70 F = T_3
T_{evap} = 20 F

Use Table F.10 for R-134a



From Table F.10.1: $P_3 = P_2 = P_{sat}$ = **85.95 psia** is minimum high P.

Since the R-134a must absorb heat transfer at the cold air 20 F, it must at least be that cold at state 4.

From Table F.10.1: $P_1 = P_4 = P_{sat}$ = **33.29 psia** is maximum low P.

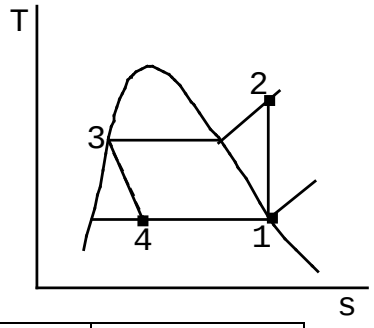
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.169E

Consider an ideal refrigeration cycle that has a condenser temperature of 110 F and an evaporator temperature of 5 F. Determine the coefficient of performance of this refrigerator for the working fluids R-134a and R-410A.

Ideal Ref. Cycle
T_{cond} = 110 F = T_3
T_{evap} = 5 F

Use Table F.10 for R-134a
Use Table F.9 for R-410A



Property for:	R-134a	R-410A
h_1, Btu/lbm	167.5	117.8
$s_2 = s_1$, Btu/lbm-R	0.4149	0.2549
P_2, lbf/in^2	161.1	380.4
T_2, F	123.7	157.3
h_2, Btu/lbm	184.7	138.4
$h_3 = h_4$, Btu/lbm	112.4	56.1
$w_C = h_2 - h_1$	17.2	20.6
$q_L = h_1 - h_4$	55.1	61.7
$\beta = q_L/(-w_C)$	3.20	3.0

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.170E

Find the high temperature, the condensing temperature, and the COP if ammonia is used in a standard refrigeration cycle with high and low pressures of 800 psia and 300 psia, respectively.

Exit evaporator x = 1 and 300 psia from F.8.2:

$$T_1 = 123.2 \text{ F}, \quad h_1 = 632.63 \text{ Btu/lbm}, \quad s_1 = 1.1356 \text{ Btu/lbm-R}$$

Exit condenser saturated liquid 800 psia from F.8.1:

$$T_3 = \mathbf{200.65\ F}, \quad h_3 = 284.17 \text{ Btu/lbm}$$

Exit compressor: 800 psia, $s = s_1$, so interpolate in F.8.2

$$T_2 = \mathbf{269\ F}, \quad h_2 = 692.65 \text{ Btu/lbm}$$

$$w_C = h_2 - h_1 = 60.02 \text{ Btu/lbm}$$

$$q_L = h_1 - h_4 = h_1 - h_3 = 348.46 \text{ Btu/lbm}$$

COP:
$$\beta = \frac{q_L}{w_c} = \frac{h_1 - h_3}{h_2 - h_1} = \frac{348.46}{60.02} = \mathbf{6.2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

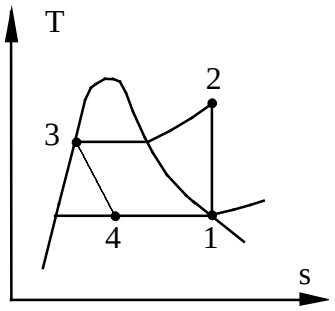
9.171E

A refrigerator receives 500 W of electrical power to the compressor driving the cycle flow of R-134a. The refrigerator operates with a condensing temperature of 100 F and a low temperature of -10 F. Find the COP for the cycle and its cooling capacity.

Solution:

Ideal refrigeration cycle
T_{cond} = 100 F = T_3
T_{evap} = -10 F = T_1

Use Table F.10



State 1: h_1 = 165.09 Btu/lbm, s_1 = 0.4162 Btu/lbm-R
State 2: $s = s_1$, $P_2 = P_3$ = 138.926 psia, h_2 = 184.02 Btu/lbm
$w_C = h_2 - h_1$ = 184.02 – 165.09 = 18.934 Btu/lbm
State 3-4: $h_4 = h_3$ = 108.86 Btu/lbm
$q_L = h_1 - h_4$ = 165.09 – 108.86 = 56.23 Btu/lbm
COP = $\beta = q_L/w_C$ = **2.97**

The cooling capacity is the rate at which it can cool

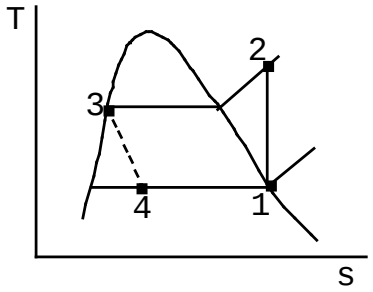
$$\dot{Q}_L = \text{COP} \times \dot{W} = 2.97 \times 500 \text{ W} = \mathbf{1485 \text{ W} = 1.407 \text{ Btu/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.172E

Consider an ideal heat pump that has a condenser temperature of 120 F and an evaporator temperature of 30 F. Determine the coefficient of performance of this heat pump for the working fluids R-410A and ammonia.

Ideal Heat Pump
T_{cond} = 120 F
T_{evap} = 30 F
Use Table F.8 for NH_3
Use Table F.9 for R-410A



Property:	R-410A		NH_3
h_1, Btu/lbm	119.9		619.5
$s_2 = s_1$	0.2482		1.2768
P_2, lbf/in^2	433.3		286.5

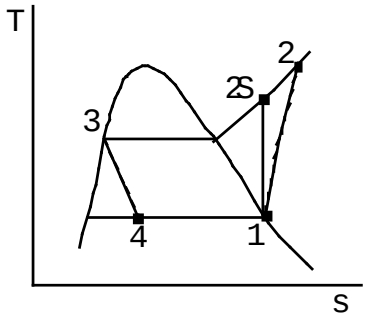
9.173E

The refrigerant R-134a is used as the working fluid in a conventional heat pump cycle. Saturated vapor enters the compressor of this unit at 50 F; its exit temperature from the compressor is measured and found to be 185 F. If the compressor exit is 300 psia, what is the isentropic efficiency of the compressor and the coefficient of performance of the heat pump?



R-134a heat pump: T_2 = 185 F

T_{EVAP} = 50 F

State 1: Table F.9.1

h_1 = 173.8 Btu/lbm,

s_1 = 0.4113 Btu/lbm R

State 2: h_2 = 193.8 Btu/lbm

Compressor work: $w_C = h_2 - h_1 = 193.8 - 173.8 = 20.0$ Btu/lbm

Isentropic compressor: $s_{2S} = s_1 = 0.4113$ Btu/lbm R

State 2s: (P_2, s) T_{2S} = 166.9 F, h_{2S} = 188.0 Btu/lbm

Ideal compressor work: $w_{C\,s} = h_{2S} - h_1 = 188.0 - 173.8 = 14.2$ Btu/lbm

The efficiency is the ratio of the two work terms

$$\eta_{S\,COMP} = \frac{w_{C\,s}}{w_C} = \frac{14.2}{20.0} = \mathbf{0.71}$$

The condenser has heat transfer as ($h_3 = h_f$ at 300 psia)

$$q_H = h_2 - h_3 = 193.8 - 130.1 = 63.7 \text{ Btu/lbm}$$

and a coefficient of performance of

$$\beta' = q_H/w_C = \mathbf{3.19}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Exergy and Combined Cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.174E

A Rankine cycle maintains 130 F in the condenser which is cooled by a 70 F reservoir. The steam out of the boiler is at 600 psia, 700 F being heated from a 900 F source. Determine the flux of exergy in or out of the reservoirs per unit mass flowing in the cycle. Find the overall cycle second law efficiency.

Solution (Cycle from problem 9.181E):

State 3: Superheated vapor $h_3 = 1350.62$ Btu/lbm, $s_3 = 1.5871$ Btu/lbm R,

State 1: Sat. liq. $h_1 = 97.97$ Btu/lbm, $v_1 = 0.01625$ ft^3/lbm, s = 0.1817 Btu/lbm R

C.V. Pump: Adiabatic and reversible. Use incompressible fluid so

$$w_P = \int v\, dP = v_1(P_2 - P_1) = 0.01625 \text{ ft}^3/\text{lbm} \times (600 - 2.2) \text{ psi} \times 144 \text{ in}^2/\text{ft}^2$$

$$= 1398.85 \text{ lbf-ft} = 1.8 \text{ Btu/lbm}$$

$$h_2 = h_1 + w_P = 97.97 + 1.8 = 99.77 \text{ Btu/lbm}$$

C.V. Boiler: $q_H = h_3 - h_2 = 1350.62 - 99.77 = 1250.85$ Btu/lbm

C.V. Tubine: $s_4 = s_3 = 1.5871$ Btu/lbm R $= 0.1817 + x_4\, 1.7292 \Rightarrow x_4 = 0.8127$,

$$h_4 = 97.97 + 0.8127 \times 1019.78 = 926.75 \text{ Btu/lbm}$$

$$w_T = h_3 - h_4 = 1350.62 - 926.75 = 423.87 \text{ Btu/lbm}$$

C.V. Condenser: $q_L = h_4 - h_1 = 926.75 - 97.97 = 828.8$ Btu/lbm

We can do the fluxes of exergy evaluarted at the reservoir T's

$$\Delta\psi_H = (1 - T_0/T_H)\, q_H = (1 - \frac{536.67}{1359.67}) \times 1250.85 = \mathbf{757.13 \text{ Btu/lbm}}$$

$$\Delta\psi_L = (1 - T_0/T_L)\, q_L = (1 - \frac{536.67}{529.67})\, 828.8 = \mathbf{-10.95 \text{ Btu/lbm}}$$

(as $T_L < T_0$ you decrease ψ)

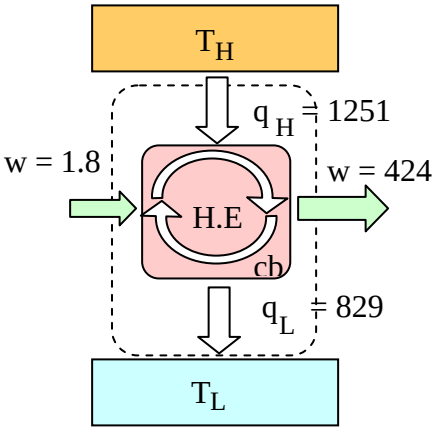
The overall second law efficiency is based on the exergy delivered from the high T source

$$\eta_{II} = \frac{w_{net}}{\Delta\psi_H} = \frac{w_T - w_P}{\Delta\psi_H} = \frac{423.87 - 1.8}{757.13} = \mathbf{0.557}$$

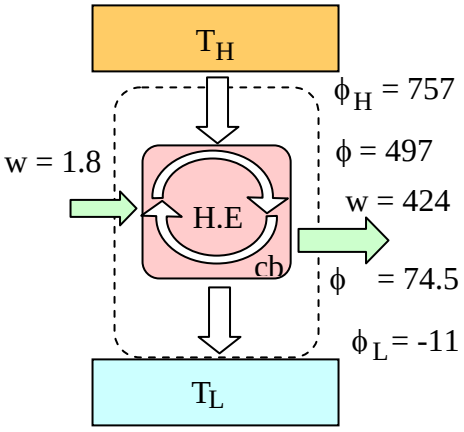
Notice $T_H > T_3$, $T_L < T_4 = T_1$, so cycle is externally irreversible. Both q_H and q_L are over finite ΔT.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Energy Transfers (Btu/lbm):



Exergy Transfers (Btu/lbm):



Comment: The exergy into the cycle from the high temperature source must be found from the flow exergies in the water as the temperature is varying.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

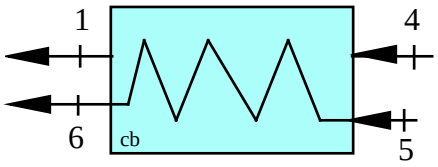
9.175E

Find the flows and fluxes of exergy in the condenser of Problem 9.154E. Use those to determine the 2nd law efficiency.

A smaller power plant produces 50 lbm/s steam at 400 psia, 1100 F, in the boiler. It cools the condenser with ocean water coming in at 60 F and returned at 65 F so that the condenser exit is at 110 F. Find the net power output and the required mass flow rate of the ocean water.

Solution:

The states properties from Tables F.7.1



State 1: 110 F, x = 0: h_1 = 78.01 Btu/lbm, s_1 = 0.1473 Btu/lbm R,

State 3: 400 psia, 1100 F: h_3 = 1577.44 Btu/lbm, s_3 = 1.7989 Btu/lbm R

C.V. Turbine : $w_T = h_3 - h_4$; $s_4 = s_3$

$s_4 = s_3 = 1.7989 = 0.1473 + x_4\,(1.8101)$ => $x_4 = 0.9124$

=> $h_4 = 78.01 + 0.9124\,(1031.28) = 1018.95$ Btu/lbm

C.V. Condenser : $q_L = h_4 - h_1 = 1018.95 - 78.01 = 940.94$ Btu/lbm

$$\dot{Q}_L = \dot{m} q_L = 50 \times 940.94 = 47\,047 \text{ Btu/s} = \dot{m}_{ocean}\, C_p\, \Delta T$$

$$\dot{m}_{ocean} = \dot{Q}_L / C_p\, \Delta T = 47\,047 / (1.0 \times 5) = 9409 \text{ lbm/s}$$

The specific flow exergy for the two states are from Eq.10.24 neglecting kinetic and potential energy

$$\psi_4 = h_4 - h_0 - T_0(s_4 - s_0), \quad \psi_1 = h_1 - h_0 - T_0(s_1 - s_0)$$

The net drop in exergy of the water is

$$\dot{\Phi}_{water} = \dot{m}_{water}\,[h_4 - h_1 - T_o(s_4 - s_1)]$$

$$= 50\,[\,1018.95 - 78.01 - 514.7\,(1.7989 - 0.1473)]$$

$$= 47\,047 - 42\,504 = \mathbf{4543\ Btu/s}$$

Notice that the reference values drops out.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

The net gain in exergy of the ocean water is

$$\dot{\Phi}_{ocean} = \dot{m}_{ocean}[h_6 - h_5 - T_o(s_6 - s_5)]$$

$$= \dot{m}_{ocean}[C_p(T_6 - T_5) - T_o C_p \ln\left(\frac{T_6}{T_5}\right)]$$

$$= 9409\ [\ 1.0\ (65 - 60) - 514.7 \times 1.0 \ln \frac{459.7 + 65}{459.7 + 60}\ ]$$

$$= 47\ 047 - 46\ 370 = \mathbf{677\ Btu/s}$$

The second law efficiency is

$$\eta_{II} = \dot{\Phi}_{ocean} / \dot{\Phi}_{water} = \frac{677}{4543} = \mathbf{0.15}$$

In reality all the exergy in the ocean water is destroyed as the 65 F water mixes with the ocean water at 60 F after it flows back out into the ocean and the efficiency does not have any significance. Notice the small rate of exergy relative to the large rates of energy being transferred.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.176E

Find the flows of exergy into and out of the feedwater heater in Problem 9.160E.

State 1: $x_1 = 0$, $h_1 = 97.97$ Btu/lbm, $v_1 = 0.01625$ ft^3/lbm, $s = 0.1817$

State 3: $x_3 = 0$, $h_3 = 330.7$ Btu/lbm, $s_3 = 0.5142$ Btu/lbm R

State 5: $h_5 = 1350.52$ Btu/lbm, $s_5 = 1.5871$ Btu/lbm R

State 6: $s_6 = s_5 = 1.5871$ Btu/lbm R => $h_6 = 1208.93$ Btu/lbm

C.V Pump P1

$$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1) = 0.01625(150 - 2.225)\frac{144}{778} = 0.44 \text{ Btu/lbm}$$

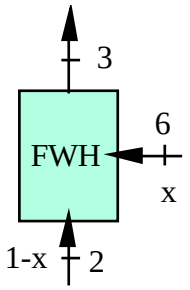
$$\Rightarrow h_2 = h_1 + w_{P1} = 97.97 + 0.44 = 98.41 \text{ Btu/lbm}$$

$$s_2 = s_1 = 0.1817 \text{ Btu/lbm R}$$

C.V. Feedwater heater: Call $\dot{m}_6 / \dot{m}_{tot} = x$ (the extraction fraction)

Energy Eq.: $(1 - x)\, h_2 + x\, h_6 = 1\, h_3$

$$x = \frac{h_3 - h_2}{h_6 - h_2} = \frac{330.7 - 98.41}{1208.93 - 98.41} = 0.2092$$



Ref. State: 14.7 psia, 77 F, $s_o = 0.08774$ Btu/lbm R, $h_o = 45.08$ Btu/lbm

$$\psi_2 = h_2 - h_o - T_o(s_2 - s_o)$$

$$= 98.41 - 45.08 - 536.67(0.1817 - 0.08774) = 2.90 \text{ Btu/lbm}$$

$$\psi_6 = 1208.93 - 45.08 - 536.67(1.5871 - 0.08774) = 359.2 \text{ Btu/lbm}$$

$$\psi_3 = 330.7 - 45.08 - 536.67(0.5142 - 0.08774) = 56.75 \text{ Btu/lbm}$$

The rate of exergy flow scaled with maximum flow rate is then

$$\dot{\Phi}_2/\dot{m}_3 = (1 - x)\, \psi_2 = 0.7908 \times 2.90 = \mathbf{2.297\ Btu/lbm}$$

$$\dot{\Phi}_6/\dot{m}_3 = x\psi_6 = 0.2092 \times 359.2 = \mathbf{75.144\ Btu/lbm}$$

$$\dot{\Phi}_3/\dot{m}_3 = \psi_3 = \mathbf{56.75\ Btu/lbm}$$

The mixing is destroying 2.297 + 75.144 – 56.75 = 20.7 Btu/lbm of exergy

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.177E

For Problem 9.162E, consider the boiler/superheater. Find the exergy destruction and the second law efficiency for the boiler-source setup.

The boiler has flow in at state 4 and out at state 5 with the source providing a q at 350 F.

Assume state 4 is saturated liquid at T_4 so $h_4 = h_{f\,4}$ => $T_4 = 68.4$ F

State 4: $h_4 = 118.4$ Btu/lbm $= h_{f\,4}$, $s_4 = s_{f\,4} = 0.2494$ Btu/lbm-R

State 5: $h_5 = 744.1$ Btu/lbm, $s_5 = 1.3062$ Btu/lbm-R

Energy Eq. $q_H = h_5 - h_4 = 744.1 - 118.4 = 625.7$ Btu/lbm

Entropy Eq. $s_4 + q_H/T_H + s_{gen} = s_5$ => $s_{gen} = s_5 - s_4 - q_H/T_H$

$$\dot{S}_{gen} = \dot{m} s_{gen} = 10\,[1.3062 - 0.2494 - \frac{625.7}{350 + 459.7}\,]$$

$$= 10 \times 0.2841 = \mathbf{2.841\ Btu/s\text{-}R}$$

The flow increase in exergy is:

$$\psi_5 - \psi_4 = h_5 - h_4 - T_o\,(s_5 - s_4) = 625.7 - 536.7\,(1.3062 - 0.2494)$$

$$= 58.62 \text{ Btu/lbm}$$

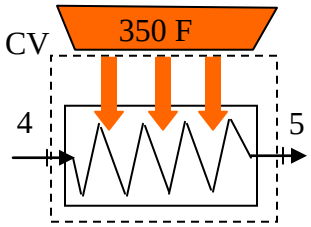
The exergy provided by the source is:

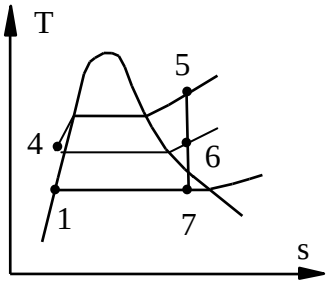
$$\phi_H = (\,1 - T_o/T_H)\,q_H = (1 - \frac{536.7}{350 + 459.7})\,625.7 = 210.96 \text{ Btu/lbm}$$

Second law efficiency is

$$\eta_{II} = \frac{\text{gain in exergy}}{\text{source exergy input}} = \frac{58.62}{210.96} = \mathbf{0.265}$$

$$(\,= 1 - T_o s_{gen}/\phi_H = 1 - 536.7 \times 0.2841 / 210.96\,)$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.178E

Steam is supplied in a line at 400 lbf/in.^{2}, 1200 F. A turbine with an isentropic efficiency of 85% is connected to the line by a valve and it exhausts to the atmosphere at 14.7 lbf/in.^{2}. If the steam is throttled down to 300 lbf/in.^{2} before entering the turbine find the actual turbine specific work. Find the change in exergy through the valve and the second law efficiency of the turbine.

C.V. Valve: Energy Eq.: $h_2 = h_1 = 1631.79$ Btu/lbm,

Entropy Eq.: $s_2 > s_1 = 1.8327$ Btu/lbm R,

State 2: $h_2, P_2 \Rightarrow s_2 = 1.86407$ Btu/lbm R

Ideal turbine: $s_3 = s_2 \Rightarrow h_{3s} = 1212.28$ Btu/lbm

$w_{T,s} = h_2 - h_{3s} = 419.51$ Btu/lbm

Actual turbine: $w_{T,ac} = \eta_T w_{T,s} =$ **356.58 Btu/lbm**

$h_{3ac} = h_2 - w_{Tac} = 1275.21$ Btu/lbm $\Rightarrow s_{3ac} = 1.9132$ Btu/lbm R

$\psi_2 - \psi_1 = h_2 - h_1 - T_0(s_2 - s_1)$

$= 0 - 536.67(1.86407 - 1.8327) = -16.835$ Btu/lbm

$w^{rev} = \psi_2 - \psi_3 = 1631.79 - 1275.21 - 536.67(1.86407 - 1.9132)$

$= 382.95$ Btu/lbm

$\eta_{II} = w_{ac}/w^{rev} = 356.58/382.95 =$ **0.931**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.179E

Find the two heat transfer rates, the total cycle exergy destruction, and the second law efficiency for the refrigerator in problem 9.171E.

A refrigerator receives 500 W of electrical power to the compressor driving the cycle flow of R-134a. The refrigerator operates with a condensing temperature of 100 F and a low temperature of -10 F. Find the COP for the cycle.

State 1: $h_1 = 165.09$ Btu/lbm, $s_1 = 0.4162$ Btu/lbm-R

State 2: $s_2 = s_1$, $P_2 = P_3 = 138.9$ psia, $h_2 = 184.02$ Btu/lbm

$w_C = h_2 - h_1 = 184.02 - 165.09 = 18.93$ Btu/lbm

State 3: $h_3 = 108.86$ Btu/lbm

State 4: $h_4 = h_3 = 108.86$ Btu/lbm,

$q_H = h_2 - h_3 = 184.02 - 108.86 = 75.16$ Btu/lbm

$q_L = h_1 - h_4 = 56.23$ Btu/lbm

$\dot{m} = \dot{W}/w_C = 0.5 \times 3412 / 18.93 = 90.12$ lbm/hr

$\dot{Q}_H = 90.12 \times 75.16 = 6773$ Btu/hr; $\dot{Q}_L = 90.12 \times 56.23 = 5067$ Btu/hr

Entropy Eq. for total C.V.: $0 = \frac{q_L}{T_L} - \frac{q_H}{T_H} + s_{gen}$

$$i = T_o\, s_{gen} = T_o \left(\frac{q_H}{T_H} - \frac{q_L}{T_L}\right) = 536.7 \left(\frac{75.16}{559.7} - \frac{56.23}{449.7}\right) = 4.96 \text{ Btu/lbm}$$

$I = \dot{m}\, i = 90.12$ lbm/hr $\times$ 4.96 Btu/lbm = **447 Btu/hr**

The cold space gain in availability

$$\Delta\psi_L = \left(1 - \frac{T_o}{T_L}\right)(-q_L) = \left(1 - \frac{536.7}{449.7}\right)(-56.23) = 10.88 \text{ Btu/lbm}$$

$$\eta_{II} = \frac{\text{output}}{\text{source}} = \frac{\Delta\psi_L}{w_C} = \frac{10.88}{18.93} = \mathbf{0.575}$$

Remark: The high temperature reservoir also gains availability so

$$\Delta\psi_H = \left(1 - \frac{T_o}{T_H}\right) q_L = \left(1 - \frac{536.7}{559.7}\right) 75.16 = 3.09 \text{ Btu/lbm}$$

the total balance is : $w_C = \Delta\psi_H + \Delta\psi_L + i = 3.09 + 10.88 + 4.96 = 18.93$ OK.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.180E

Consider an ideal dual-loop heat-powered refrigeration cycle using R-134a as the working fluid, as shown in Fig. P9.135. Saturated vapor at 200 F leaves the boiler and expands in the turbine to the condenser pressure. Saturated vapor at 0 F leaves the evaporator and is compressed to the condenser pressure. The ratio of the flows through the two loops is such that the turbine produces just enough power to drive the compressor. The two exiting streams mix together and enter the condenser. Saturated liquid leaving the condenser at 110 F is then separated into two streams in the necessary proportions. Determine the ratio of mass flow rate through the power loop to that through the refrigeration loop. Find also the performance of the cycle, in terms of the ratio Q_L/Q_H.

	T	P	h	s
	F	lbf/in^2	Btu/lbm	Btu/lbm R
1	0	22.2	166.8	0.4154
2	-	161.1		0.4154
3	110	161.1	112.4	0.067 45
4	0	21.2	112.4	
5	-	503.6		
6	200	503.6	181.7	0.3955
7	110	161.1		0.3955

Computer tables for properties.

$P_2=P_3=P_{SAT}$ at 110 F

$P_5=P_6=P_{SAT}$ at 200 F

$s_2=s_1=0.4154$

$h_2 = 185.0$

Pump work:

$w_P = h_5-h_3$

$\approx v_3(P_5-P_3)$

$$w_P = 0.01415(503.6 - 161.1)\frac{144}{778} = 0.897 \text{ Btu/lbm}$$

$$h_5 = 112.4 + 0.897 = 113.3 \text{ Btu/lbm}$$

$$s_7 = s_6 = 0.3955 = 0.2881 + x_7(0.1203) \quad \Rightarrow \quad x_7 = 0.8928$$

$$h_7 = 112.4 + 0.8928\ (68.5) = 173.6 \text{ Btu/lbm}$$

9.181E

The power plant in Problem 9.147E is modified to have a superheater section following the boiler so the steam leaves the super heater at 600 lbf/in.^{2}, 700 F. Find the specific work and heat transfer in each of the ideal components and the cycle efficiency.

Solution:

For this cycle from Table F.7

State 3: Superheated vapor $h_3 = 1350.62$ Btu/lbm, $s_3 = 1.5871$ Btu/lbm R,

State 1: Saturated liquid $h_1 = 97.97$ Btu/lbm, $v_1 = 0.01625$ ft^3/lbm

C.V. Pump: Adiabatic and reversible. Use incompressible fluid so

$$w_P = \int v\, dP = v_1(P_2 - P_1) = 0.01625(600 - 2.2)\frac{144}{778} = \mathbf{1.8\ Btu/lbm}$$

$$h_2 = h_1 + w_P = 97.97 + 1.8 = 99.77 \text{ Btu/lbm}$$

C.V. Boiler: $q_H = h_3 - h_2 = 1350.62 - 99.77 = \mathbf{1250.85\ Btu/lbm}$

C.V. Tubine: $w_T = h_3 - h_4$, $s_4 = s_3$

$$s_4 = s_3 = 1.5871 \text{ Btu/lbm R} = 0.1817 + x_4\, 1.7292 \quad \Rightarrow \quad x_4 = 0.8127,$$

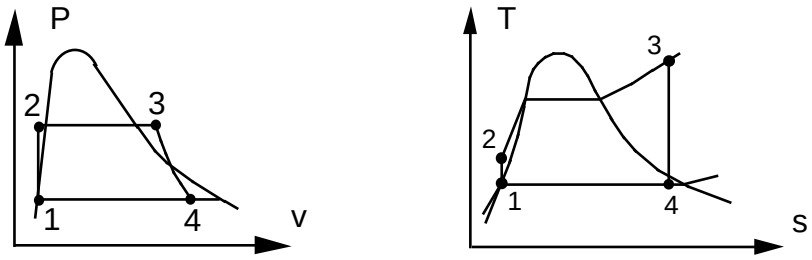
$$h_4 = 97.97 + 0.8127 \times 1019.78 = 926.75 \text{ Btu/lbm}$$

$$w_T = 1350.62 - 926.75 = \mathbf{423.87\ Btu/lbm}$$

$$\eta_{CYCLE} = (w_T - w_P)/q_H = (423.87 - 1.8)/1250.85 = \mathbf{0.337}$$

C.V. Condenser:

$$q_L = h_4 - h_1 = 926.75 - 97.97 = \mathbf{828.8\ Btu/lbm}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

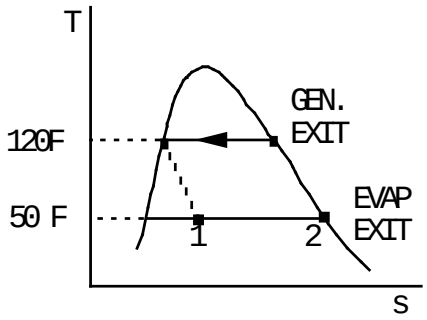
9.182E

Consider a small ammonia absorption refrigeration cycle that is powered by solar energy and is to be used as an air conditioner. Saturated vapor ammonia leaves the generator at 120 F, and saturated vapor leaves the evaporator at 50 F. If 3000 Btu of heat is required in the generator (solar collector) per pound-mass of ammonia vapor generated, determine the overall performance of this system.

NH_3 absorption cycle:

sat. vapor at 120 F exits the generator.
Sat. vapor at 50 F exits the evaporator

$q_H = q_{GEN} = 3000$ Btu/lbm NH_3 out of generator.



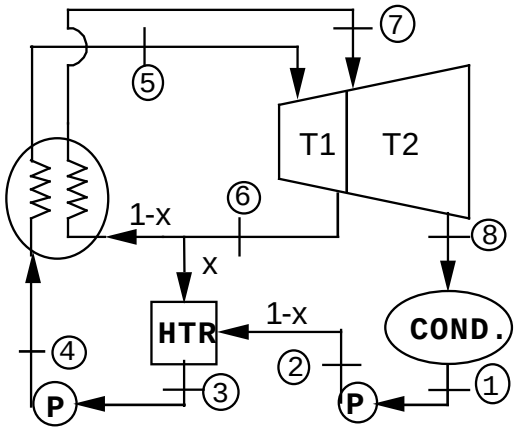
$q_L = h_2 - h_1 = h_{G\ 50\ F} - h_{F\ 120\ F} = 624.28 - 178.79$

$= 445.49$ Btu/lbm $\Rightarrow$ $q_L/q_H = 445.49/3000 =$ **0.1485**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.183E

Consider an ideal combined reheat and regenerative cycle in which steam enters the high-pressure turbine at 500 lbf/in.^{2}, 700 F, and is extracted to an open feedwater heater at 120 lbf/in.^{2} with exit as saturated liquid. The remainder of the steam is reheated to 700 F at this pressure, 120 lbf/in.^{2}, and is fed to the low-pressure turbine. The condenser pressure is 2.225 lbf/in.^{2}. Calculate the thermal efficiency of the cycle and the net work per pound-mass of steam.



5: $h_5 = 1356.66$, $s_5 = 1.6112$

7: $h_7 = 1378.17$, $s_7 = 1.7825$

3: $h_3 = h_f = 312.59$, $v_3 = 0.01788$

C.V. T1

$s_5 = s_6$ => $h_6 = 1209.76$

$w_{T1} = h_5 - h_6 = 1356.66 - 1209.76$

$= 146.9$ Btu/lbm

C.V. Pump 1

$w_{P1} = h_2 - h_1 = v_1(P_2 - P_1)$

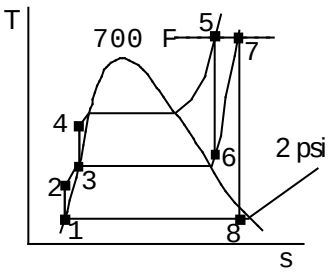
$= 0.01623(120 - 2) = 0.354$

=> $h_2 = h_1 + w_{P1} = 93.73 + 0.354 = 94.08$ Btu/lbm

C.V. FWH

$x\, h_6 + (1 - x)\, h_2 = h_3$

$$x = \frac{h_3 - h_2}{h_6 - h_2} = \frac{312.59 - 94.08}{1209.76 - 94.08} = 0.1958$$



C.V. Pump 2

$w_{P2} = h_4 - h_3 = v_3(P_4 - P_3) = 0.01788(500 - 120)(144/778) = 1.26$ Btu/lbm

=> $h_4 = h_3 + w_{P2} = 312.59 + 1.26 = 313.85$ Btu/lbm

$q_H = h_5 - h_4 + (1 - x)(h_7 - h_6) = 1042.81 + 135.43 = 1178.2$ Btu/lbm

C.V. Turbine 2

$s_7 = s_8$ => $x_8 = (1.7825 - 0.1817)/1.7292 = 0.9257$

$h_8 = h_f + x_8\, h_{fg} = 97.97 + 0.9257 \times 1019.78 = 1041.98$

$w_{T2} = h_7 - h_8 = 1378.17 - 1041.98 = 336.19$

$w_{net} = w_{T1} + (1 - x)\, w_{T2} - (1 - x)\, w_{P1} - w_{P2}$

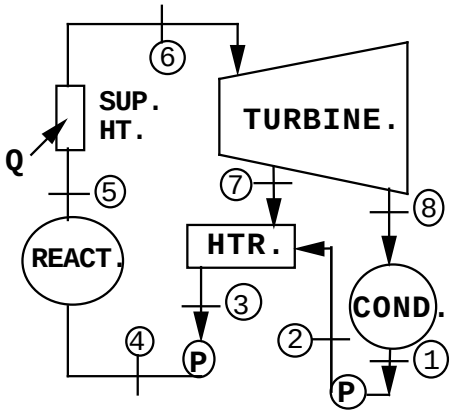
$= 146.9 + 270.36 - 0.285 - 1.26 =$ **415.72 kJ/kg**

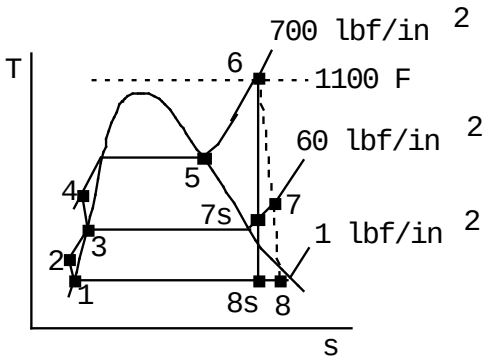
$\eta_{cycle} = w_{net} / q_H = 415.72 / 1178.2 =$ **0.353**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.184E

In one type of nuclear power plant, heat is transferred in the nuclear reactor to liquid sodium. The liquid sodium is then pumped through a heat exchanger where heat is transferred to boiling water. Saturated vapor steam at 700 lbf/in.^{2} exits this heat exchanger and is then superheated to 1100 F in an external gas-fired superheater. The steam enters the turbine, which has one (open-type) feedwater extraction at 60 lbf/in.^{2}. The isentropic turbine efficiency is 87%, and the condenser pressure is 0.95 lbf/in.^{2}. Determine the heat transfer in the reactor and in the superheater to produce a net power output of 1000 Btu/s.





$\dot{W}_{NET}$ = 1000 Btu/s, η_{ST} = 0.87

CV Pump 1

$w_{P12} = 0.016136(60 - 1)144/778 = 0.18$ Btu/lbm

$h_2 = h_1 + w_{P12} = 69.73 + 0.18 = 69.91$ Btu/lbm

CV Pump 2

$w_{P34} = 0.017378(700 - 60)144/778 = 2.06$ Btu/lbm

$h_4 = h_3 + w_{P34} = 262.24 + 2.06 = 264.3$ Btu/lbm

CV HP Turbine section

$s_{7S} = s_6 = 1.7682$, P_7 => $T_{7S} = 500.8$ F, $h_{7S} = 1283.4$ Btu/lbm

$h_7 = h_6 - \eta_{ST}(h_6 - h_{7S}) = 1625.8 - 0.87(1625.8 - 1283.4) = 1327.9$

CV LP Turbine section

$s_{8S} = s_6 = 1.7682 = 0.1296 + x_{8S} \times 1.8526$ => $x_{8S} = 0.8845$

$h_{8S} = 68.04 + 0.8845 \times 1036.98 = 985.25$ Btu/lbm

$h_8 = h_6 - \eta_{ST}(h_6 - h_{8S}) = 1625.8 - 0.87(1625.8 - 985.25) = 1068.5$ Btu/lbm

CV Feedwater heater: Continuity Eq.: $m_2 + m_7 = m_3 = 1.0$ lbm,

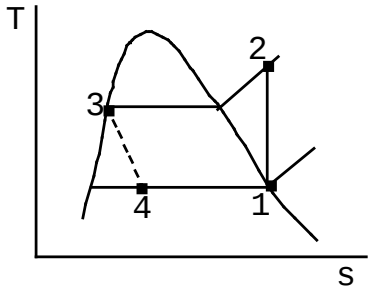
9.192-eE

Consider an ideal heat pump that has a condenser temperature of 120 F and an evaporator temperature of 30 F. Determine the coefficient of performance of this heat pump for the working fluid R-12.

Ideal Heat Pump
T_{cond} = 120 F
T_{evap} = 30 F

Use computer table for R-12



Property/parameter	R-12
h_1, Btu/lbm	80.42
$s_2 = s_1$, Btu/lbm-R	0.1665
P_2, lbf/in^2	172.3
T_2, F	132.2
h_2, Btu/lbm	91.0
$h_3 = h_4$, Btu/lbm	36.011
$-w_C = h_2 - h_1$	10.58
$q_H = h_2 - h_3$	54.995
$\beta' = q_H/(-w_C)$	5.198

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.193-dE

Do Problem 9.151 with R-22 as the working fluid.

Standard Rankine cycle with properties from the computer R-22 tables,

$h_1 = 39.267$ Btu/lbm, $v_1 = 0.01404$ ft^3/lbm, $P_1 = 210.6$ psia,

$P_2 = P_3 = 554.8$ psia, $h_3 = 110.07$ Btu/lbm, $s_3 = 0.1913$ Btu/lbm R

CV: Pump $w_P = v_1(P_2 - P_1) = 0.01404\ (554.8 - 210.6)\frac{144}{778} = 0.894$ Btu/lbm

$h_2 = h_1 + w_P = 39.267 + 0.894 = 40.16$ Btu/lbm

CV: Turbine $s_4 = s_3$

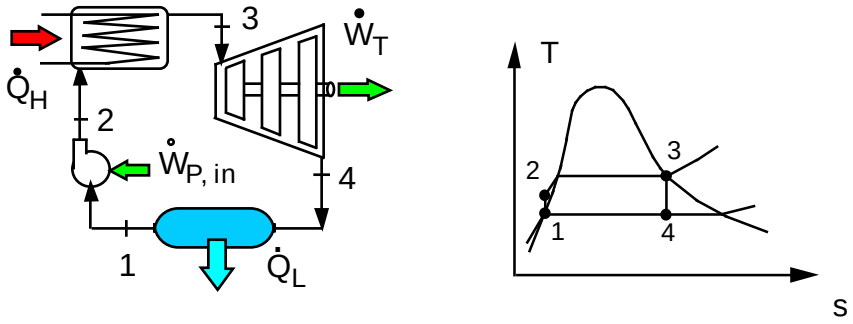
$\Rightarrow x_4 = (0.1913 - 0.07942)/0.13014 = 0.9442$

$h_4 = 101.885$ Btu/lbm, $w_T = h_3 - h_4 = 8.185$ Btu/lbm

CV: Boiler

$q_H = h_3 - h_2 = 110.07 - 40.16 = 69.91$ Btu/lbm

$\eta_{TH} = (w_T - w_P)/q_H = (8.185 - 0.894)/157.21 =$ **0.104**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

9.195E

The simple steam power plant in Problem 4.180E, shown in Fig P4.121 has a turbine with given inlet and exit states. Find the exergy at the turbine exit, state 6. Find the second law efficiency for the turbine, neglecting kinetic energy at state 5. Use CATT3 to solve.

Properties from Problem 4.180E and s values from F.7.2.

$h_6 = 1029$, $h_5 = 1455.6$, $h_o = 45.08$ all in Btu/lbm

$s_5 = 1.6408$, $s_6 = 1.8053$, $s_o = 0.08769$ all in Btu/lbm R

Kinetic energy at state 6: $KE_6 = 0.5\mathbf{V}_6^2 = 600^2 /(2 \times 25\,037) = 7.19$ Btu/lbm

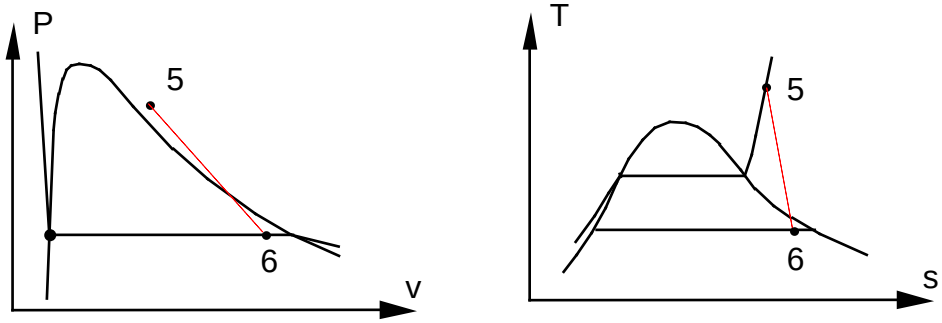
Recall 1 Btu/lbm = 25 037 ft^2/s^2

$\psi_6 = h_6 + KE_6 - h_o - T_o (s_6 - s_o) = 61.26$ Btu/lbm

$w^{rev} = \psi_5 - \psi_6 = h_5 - h_6 - T_o(s_5 - s_6) = 515.2$ Btu/lbm

$w^{AC} = h_5 - h_6 = 426.9$ Btu/lbm

$\eta_{II} = w^{ac} / w^{rev} = 426.9 / 515.2 =$ **0.829**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

In-Text Concept Questions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.a

The Brayton cycle has the same 4 processes as the Rankine cycle, but the T-s and P-v diagrams look very different; why is that?

The Brayton cycle have all processes in the superheated vapor (close to ideal gas) region. The Rankine cycle crosses in over the two-phase region.

10.b

Is it always possible to add a regenerator to the Brayton cycle? What happens when the pressure ratio is increased?

No. When the pressure ratio is high, the temperature after compression is higher than the temperature after expansion. The exhaust flow can then not heat the flow into the combustor.

10.c

Why would you use an intercooler between compressor stages?

The cooler provides two effects. It reduces the specific volume and thus reduces the work in the following compressor stage. It also reduces the temperature into the combustor and thus lowers the peak temperature. This makes the control of the combustion process easier (no autoignition or uncontrollable flame spread), it reduces the formation of NOx that takes place at high temperatures and lowers the cooling requirements for the chamber walls.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.d

The jet engine does not produce shaft work; how is power produced?

The turbine produces just enough shaft work to drive the compressor and it makes a little electric power for the aircraft. The power is produced as thrust of the engine. In order to exhaust the gases at high speed they must be accelerated so the high pressure in the turbine exit provides that force (high P relative to ambient). The high P into the turbine is made by the compressor, which pushes the flow backwards, and thus has a net resulting force forwards on the blades transmitted to the shaft and the aircraft. The outer housing also has a higher pressure inside that gives a net component in the forward direction.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.e

How is the compression in the Otto cycle different from the Brayton cycle?

The compression in an Otto cycle is a volume reduction dictated by the piston motion. The physical handles are the volumes V_1 and V_2.

The compression in a Brayton cycle is the compressor pushing on the flow so it determines the pressure. The physical control is the pressure P_2 determined by how much torque you drive the shaft with.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.f

How many parameters do you need to know to completely describe the Otto cycle? How about the Diesel cycle?

Otto cycle. State 1 (2 parameters) and the compression ratio CR and the energy release per unit mass in the combustion, a total of **4 parameters**. With that information you can draw the diagrams in Figure 10.2. Another way of looking at it is four states (8 properties) minus the four process equations ($s_2 = s_1$, $v_3 = v_2$, $s_4 = s_3$ and $v_4 = v_1$) gives 4 unknowns.

Diesel cycle. Same as for the Otto cycle namely **4 parameters**. The only difference is that one constant v process is changed to a constant P process.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.g

The exhaust and inlet flow processes are not included in the Otto or Diesel cycles. How do these necessary processes affect the cycle performance?

Due to the pressure loss in the intake system and the dynamic flow process we will not have as much mass in the cylinder or as high a P as in a reversible process. The exhaust flow requires a slightly higher pressure to push the flow out through the catalytic converter and the muffler (higher back pressure) and the pressure loss in the valve so again there is a loss relative to a reversible process. Both of these processes subtract a pumping work from the net work out of the engine and a lower charge mass gives less power (not necessarily lower efficiency) than otherwise could be obtained.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Concept-Study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.1

Is a Brayton cycle the same as a Carnot cycle? Name the four processes.

No. The Brayton cycle approximates a gas turbine.

1-2:	An isentropic compression (constant s)	Compressor
2-3:	An isobaric heating (constant P)	Combustor
3-4:	An isentropic expansion (constant s)	Turbine
4-1:	An isobaric cooling, heat rejection (constant P)	Heat exchanger

Comment: This cycle is the same as the Rankine cycle 4 processes, but it takes place in the ideal gas region of states. The last process does not exist in the real gas turbine which is an open cycle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.2

Why is the back work ratio in the Brayton cycle much higher than in the Rankine cycle?

Recall the expression for shaft work in a steady flow device

$$w = -\int v\, dP + \ldots.$$

The specific volume in the compressor is not so much smaller than the specific volume in the turbine of the Brayton cycle as it is in the pump (liquid) compared to turbine (superheated vapor) in the Rankine cycle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.3

For a given Brayton cycle the cold air approximation gave a formula for the efficiency. If we use the specific heats at the average temperature for each change in enthalpy will that give a higher or lower efficiency?

The specific heats are increasing functions of temperature. As the expression for the efficiency is from p.464

$$\eta = 1 - \frac{h_4 - h_1}{h_3 - h_2} = 1 - \frac{C_{P\,4\text{-}1}}{C_{P\,3\text{-}2}} \frac{T_4 - T_1}{T_3 - T_2}$$

The average T from 4 to 1 is lower than the average T from 2 to 3 and therefore the ratio of the two specific heats is lower than one yielding a **higher efficiency** than the cold air approximation gives for a given set of temperatures. However, the temperature ratios are different from the cold air calculation for the same compression ratio so the final result is a little more complex.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.4

Does the efficiency of a jet engine change with altitude since the density varies?

No, just like the standard Brayton cycle the simple model performance depends only on the compression ratio.

10.5

Why are the two turbines in Figures 10.8-9 not connected to the same shaft?

Such a configuration gives a little more flexibility in the control of the cycle under varying loads. The two turbines would then not have to run at the same speed for various power output levels.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.6

Why is an air refrigeration cycle not common for a household refrigerator?

The capacity of the air cycle per mass flowing through the system is very small compared with the vapor compression cycle. The cycle also includes the expander which is one more piece of equipment that will add cost and maintenance requirements to the system.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.7

Does the inlet state (P_1, T_1) have any influence on the Otto cycle efficiency? How about the power produced by a real car engine?

Very little. The efficiency for the ideal cycle only depends on compression ratio when we assume cold air properties. The u's are slightly non-linear in T so there will be a small effect.

In a real engine there are several effects. The inlet state determines the density and thus the total mass in the chamber. The more mass the more energy is released when the fuel burns, the peak P and T will also change which affects the heat transfer loss to the walls and the formation of NOx (sensitive to T). The combustion process may become uncontrollable if T is too high (knocking). Some increase in P_1 like that done by a turbo-charger or super-charger increases the power output and if high, it must be followed by an intercooler to reduce T_1. If P_1 is too high the losses starts to be more than the gain so there is an optimum level.

10.8

For a given compression ratio does an Otto cycle have higher or lower efficiency than a diesel cycle?

This is actually not clear from the formula's so we need to refer to the T-s diagram where we see that the average T at which the heat is added is higher for the Otto cycle than the diesel cycle for the same compression ratio. However since the diesel cycle runs with much higher compressions ratios than the Otto cycle most typical diesel cycles have higher efficiency than typical Otto cycles.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.9

How many parameters do you need to know to completely describe the Atkinson cycle? How about the Miller cycle?

Four parameters for the Atkinson cycle. A total of 8 properties minus four known process equations give 4 unknowns.

The Miller cycle has one additional process so that requires one more parameter for a total of **five**. That is 10 properties with 5 known process equations leaving 5 unknowns.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.10

Why would one consider a combined cycle system for a power plant? For a heat pump or refrigerator?

Dual cycle or combined cycle systems have the advantage of a smaller difference between the high and low ranges for P and T. The heat can be added at several different temperatures reducing the difference between the energy source T and the working substance T. The working substance vapor pressure at the desired T can be reduced from a high value by adding a topping cycle with a different substance or have a higher low pressure at very low temperatures.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.11

Can the exhaust flow from a gas turbine be useful?

Usually the temperature in the exhaust flow is fairly high compared to ambient conditions so we could use the hot exhaust flow energy. It could be used directly for heating purposes in process applications or heating of buildings. As a topping cycle it can be used to heat/boil water for use in a Rankine cycle.

10.12

Where may a heat engine driven refrigerator be useful?

Any remote location where electricity is not available. Since a rotating shaft is available in a car engine the car A/C unit is driven by a belt engaged with a magnetic clutch so you do not have to have an electric motor.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.13

Since any heat transfer is driven by a temperature difference, how does that affect all the real cycles relative to the ideal cycles?

Heat transfers are given as $\dot{Q} = CA\ \Delta T$ so to have a reasonable rate the area and the temperature difference must be large. The working substance then must have a different temperature than the ambient it exchanges energy with. This gives a smaller temperature difference for a heat engine with a lower efficiency as a result. The refrigerator or heat pump must have the working substance with a higher temperature difference than the reservoirs and thus a lower coefficient of performance (COP).

The smaller CA is, the larger ΔT must be for a certain magnitude of the heat transfer rate. This can be a design problem, think about the front end air intake grill for a modern car which is very small compared to a car 20 years ago.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.14

In an Otto cycle the cranking mechanism dictates the volume given the crank position. Can you say something similar for the Brayton cycle?

Yes, in the Brayton cycle the compressor determines the high pressure, the more compressor work input there is, the harder it pushes on the gas leading to a higher exit pressure. So in the Brayton cycle the pressure ratio is one of the design parameters just like the volume compression ratio is in a piston cylinder type of cycle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.15

For all the gas cycles it is assumed the ideal compression and expansions are isentropic. This is approximated with a polytropic process having n = k. The expansion after combustion will have some heat loss due to high temperature so what does that imply for the value of n?

In the expansion of the hot gases we can expect a heat loss to the cooler walls so a q out means a decrease in entropy. The polytropic processes as plotted in Fig. 6.13 shows what happens. In an expansion volume goes up so P and T drops then if entropy must decrease it means n > k.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.16

For all the gas cycles it is assumed the ideal compression and expansions are isentropic. This is approximated with a polytropic process having n = k. The compression in a diesel engine leads to high temperatures and thus will have some heat loss so what does that imply for the value of n?

In the compression of air P and T go up, see Fig. 6.13. The start of the process may have n = k as the temperature of the air is not too different from the wall temperature. As the air gets hotter it will lose heat to the walls and thus entropy will decrease. Moving up and to the left in the T-s diagram corresponds to a process with n < k.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.17

If we compute the efficiency of an Otto or Diesel cycle we get something like 60% for a compression ratio of 10:1. Is a real engine close to this?

Not at all. A gasoline engine has an efficiency of about 35% pushing it to 40% for a hybrid configuration. Diesel engines can be about 40-45% with bigger two stroke engines, like for ships, having the higher efficiencies. Scale helps in that heat loss and flow losses scale with area whereas power scales with volume. This also means that very small engines have the smallest efficiency as the losses become significant.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.18

A hybrid powertrain couples a battery/motor with an internal combustion engine. Mention a few factors that make this combination a little more efficient.

1. The combustion engine can be operated in a narrow range of RPM and load (throttle) conditions. This means it can be optimized for that narrow range.

2. The combustion engine does not have to accelerate and go through a transient period with extra fuel or decelerate and idle with no useful power output.

3. The combustion engine can be smaller and operate at full throttle cutting pumping losses and fully use all components that do not need to be designed for a larger capacity. In a standard car all systems must be designed for the maximum expected load, which is used 2% of the time if ever, thus adding mass, increasing warm up time etc.

4. With electric motors driving the wheels regenerative braking can be used. This means the motors act as electrical generators and charge the battery during braking.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Brayton Cycles, Gas Turbines

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.19

In a Brayton cycle the inlet is at 300 K, 100 kPa and the combustion adds 800 kJ/kg. The maximum temperature is 1400 K due to material considerations. Find the maximum permissible compression ratio and for that the cycle efficiency using cold air properties.

Solution:

Combustion: $h_3 = h_2 + q_H$; $\quad {}_2w_3 = 0$ and $T_{max} = T_3 = 1400$ K

$$T_2 = T_3 - q_H/C_P = 1400 \text{ K} - 800 \text{ kJ/kg} / 1.004 \text{ kJ/kg-K} = 603.2 \text{ K}$$

Reversible adiabatic compression leads to constant s, from Eq.6.23:

$$P_2 / P_1 = (T_2/T_1)^{\frac{k}{k-1}} = (603.2/300)^{3.5} = \mathbf{11.53}$$

Reversible adiabatic expansion leads to constant s, from Eq.6.23

$$T_4 = T_3 (P_4/P_3)^{\frac{k-1}{k}} = T_3 \, T_1/T_2 = 1400 \, \frac{300}{603.2} = 696.3 \text{ K}$$

For net work we get

$$w_T = C_P (T_3 - T_4) = 1.004(1400 - 696.3) = 706.5 \text{ kJ/kg}$$

$$w_C = C_P (T_2 - T_1) = 1.004(603.2 - 300) = 304.4 \text{ kJ/kg}$$

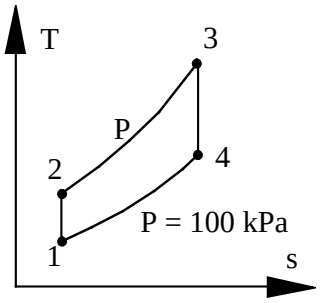
$$w_{net} = w_T - w_C = 706.5 - 304.4 = 402.1 \text{ kJ/kg}$$

$$\eta = w_{net} / q_H = 402.1 / 800 = \mathbf{0.503}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.20

A Brayton cycle has compression ratio of 15:1 with a high temperature of 1600 K and the inlet at 290 K, 100 kPa. Use cold air properties and find the specific heat addition and specific net work output.



Brayton cycle so this means:

Minimum T: $T_1 = 290$ K

Maximum T: $T_3 = 1600$ K

Pressure ratio: $P_2/P_1 = 15$

Compression in compressor: $s_2 = s_1$

$\Rightarrow$ Implemented in Eq.6.23

$$T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 290\ \text{K}\ (15)^{0.286} = 628.65\ \text{K}$$

Energy input is from the combustor

$$q_H = C_{P0}(T_3 - T_2) = 1.004\ (1600 - 628.65) = \mathbf{975.2\ kJ/kg}$$

Do the overall cycle efficiency and the net work

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 15^{-0.4/1.4} = 0.5387$$

$$w_{NET} = \eta\, q_H = 0.5387 \times 975.2 = \mathbf{525.34\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.21

A large stationary Brayton cycle gas-turbine power plant delivers a power output of 100 MW to an electric generator. The minimum temperature in the cycle is 300 K, and the exhaust temperature is 750 K. The minimum pressure in the cycle is 100 kPa, and the compressor pressure ratio is 14 to 1. Calculate the power output of the turbine. What fraction of the turbine output is required to drive the compressor? What is the thermal efficiency of the cycle?

Solution:

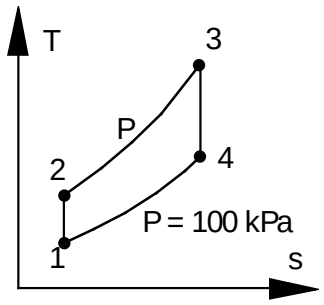
Brayton cycle so this means:

Minimum T: $T_1 = 300$ K

Exhaust T: $T_4 = 750$ K

Pressure ratio: $P_2/P_1 = 14$

Solve using constant C_{P0}



Compression in compressor: $s_2 = s_1 \Rightarrow$ Implemented in Eq.6.23

$$T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 300 \text{ K} \times (14)^{0.286} = 638.1 \text{ K}$$

$$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 1.004\ (638.1 - 300) = 339.5 \text{ kJ/kg}$$

Expansion in turbine: $s_4 = s_3 \Rightarrow$ Implemented in Eq.6.23

$$T_3 = T_4\,(P_3/P_4)^{\frac{k-1}{k}} = 750 \text{ K} \times (14)^{0.286} = 1594 \text{ K}$$

$$w_T = h_3 - h_4 = C_{P0}(T_3 - T_4) = 1.004\ (1594 - 750) = 847.4 \text{ kJ/kg}$$

$$w_{NET} = 847.4 - 339.5 = 507.9 \text{ kJ/kg}$$

Do the overall net and cycle efficiency

$$\dot{m} = \dot{W}_{NET}/w_{NET} = 100\,000 \text{ kW}/507.9 \text{ kJ/kg} = 196.9 \text{ kg/s}$$

$$\dot{W}_T = \dot{m} w_T = 196.9 \text{ kg/s} \times 847.4 \text{ kJ/kg} = \mathbf{166.85\ MW}$$

$$w_C/w_T = 339.5/847.4 = \mathbf{0.40}$$

Energy input is from the combustor

$$q_H = C_{P0}(T_3 - T_2) = 1.004\ (1594 - 638.1) = 959.7 \text{ kJ/kg}$$

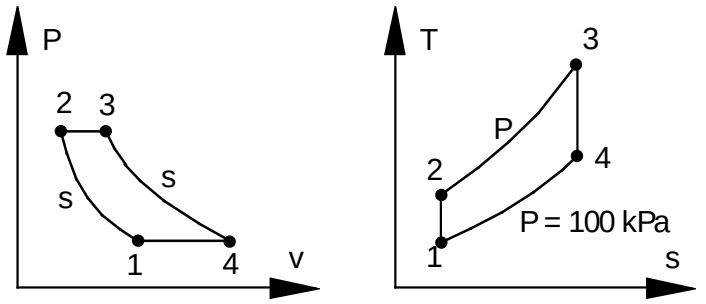
$$\eta_{TH} = w_{NET}/q_H = 507.9/959.7 = \mathbf{0.529}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.22

Consider an ideal air-standard Brayton cycle in which the air into the compressor is at 100 kPa, 20°C, and the pressure ratio across the compressor is 12:1. The maximum temperature in the cycle is 1100°C, and the air flow rate is 10 kg/s. Assume constant specific heat for the air, value from Table A.5. Determine the compressor work, the turbine work, and the thermal efficiency of the cycle.

Solution:



Compression ratio

$$\frac{P_2}{P_1} = 12$$

Max temperature

$$T_3 = 1100^{o}C$$

$$\dot{m} = 10 \text{ kg/s}$$

The compression is reversible and adiabatic so constant s. From Eq.6.23

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 293.2 \text{ K} \times (12)^{0.286} = 596.8 \text{ K}$$

Energy equation with compressor work in

$$w_C = -{}_1w_2 = C_{P0}(T_2 - T_1) = 1.004(596.8 - 293.2) = 304.8 \text{ kJ/kg}$$

The expansion is reversible and adiabatic so constant s. From Eq.6.23

$$T_4 = T_3\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}} = 1373.2 \text{ K}\left(\frac{1}{12}\right)^{0.286} = 674.7 \text{ K}$$

Energy equation with turbine work out

$$w_T = C_{P0}(T_3 - T_4) = 1.004(1373.2 - 674.7) = 701.3 \text{ kJ/kg}$$

Scale the work with the mass flow rate

$$\dot{W}_C = \dot{m}w_C = \mathbf{3048\ kW}, \qquad \dot{W}_T = \dot{m}w_T = \mathbf{7013\ kW}$$

Energy added by the combustion process

$$q_H = C_{P0}(T_3 - T_2) = 1.004(1373.2 - 596.8) = 779.5 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = (701.3 - 304.8)/779.5 = \mathbf{0.509}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.23

A Brayton cycle has air into the compressor at 95 kPa, 290 K and has an efficiency of 50%. The exhaust temperature is 675 K. Find the pressure ratio and the specific heat addition by the combustion for this cycle.

The efficiency is given by the compression ratio so we get

$$\eta = 1 - r_p^{-(k-1)/k} = 0.5 \quad => \quad r_p = P_2/P_1 = (1/0.5)^{\frac{k}{k-1}} = 2^{3.5} = \mathbf{11.314}$$

The compression is reversible and adiabatic so constant s. From Eq.6.23

$$T_2 = T_1 \, r_p^{(k-1)/k} = 290 \text{ K} \times (11.314)^{0.4/1.4} = 580 \text{ K}$$

The expansion process gives

$$T_3 = T_4 \, r_p^{(k-1)/k} = 675 \text{ K} \times (11.314)^{0.4/1.4} = 1350 \text{ K}$$

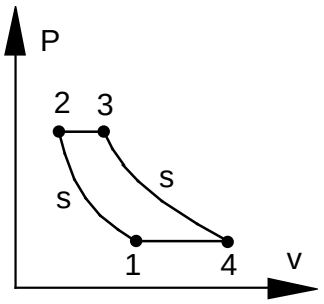
Energy added by the combustion process

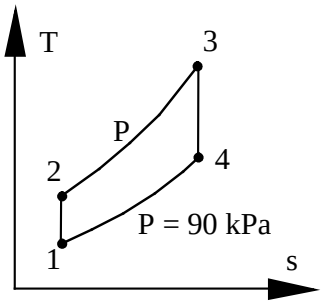
$$q_H = C_{P0}(T_3 - T_2) = 1.004 \text{ kJ/kg-K} \times (1350 - 580) \text{ K} = \mathbf{773 \text{ kJ/kg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.24

A Brayton cycle has inlet at 290 K, 90 kPa and the combustion adds 1000 kJ/kg. How high can the compression ratio be so the highest temperature is below 1700 K? Use cold air properties to solve.





Compression ratio
$r_p = P_2 / P_1$
Max temperature
$T_3 = 1700$ K
Combustion adds
${}_2q_3 = h_3 - h_2$

Let us work back from state 3 to 2 as

${}_2q_3 = h_3 - h_2 = C_{P0}(T_3 - T_2) \Rightarrow$

$T_2 = T_3 - {}_2q_3 / C_{P0} = 1700$ K $- 1000$ kJ/kg $/ 1.004$ kJ/kg-K $= 704$ K

The compression is reversible and adiabatic so constant s. From Eq.6.23

$$T_2 = T_1 \, r_p^{(k-1)/k} \Rightarrow \quad r_p = \left(\frac{T_2}{T_1}\right)^{\frac{k}{k-1}} = \left(\frac{704}{290}\right)^{3.5} = \mathbf{22.29}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.25

Assume a state of 1400 kPa, 2100 K into the turbine section of a Brayton cycle with an adiabatic expansion to 100 kPa and the compressor inlet temperature is 300 K. Find the missing temperatures in the cycle using Table A.7 and then give the average value of k (ratio of specific heats) for the compression and expansion processes.

Compression process:

$$s^o_{T2} = s^o_{T1} + R \ln(P_2/P_1) = 6.86926 + 0.287 \ln(14) = 7.62667 \text{ kJ/kg-K}$$

$T_2 =$ **629.4 K** and $h_2 = 638.3$ kJ/kg

Expansion process:

$$s^o_{T4} = s^o_{T3} + R \ln(P_4/P_3) = 9.02721 + 0.287 \ln(1/14) = 8.26980 \text{ kJ/kg-K}$$

$T_4 =$ **1124.5 K** and $h_4 = 1189.6$ kJ/kg

In the compression process

$$C_P = (h_2 - h_1)/(T_2 - T_1) = \frac{638.3 - 300.47}{629.4 - 300} = 1.0256 \text{ kJ/kg-K}$$

$$k = C_P/(C_P - R) = \frac{1.0256}{1.0256 - 0.287} = \mathbf{1.3886}$$

In the expansion process

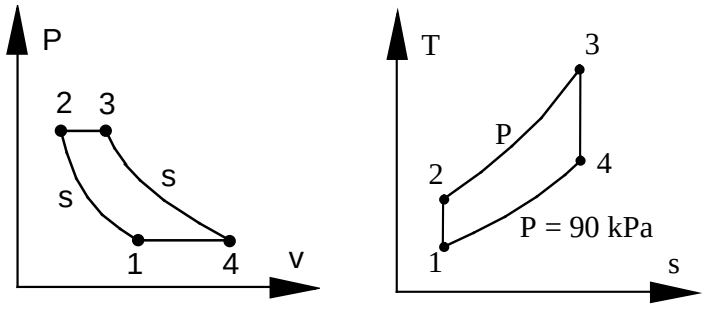
$$C_P = (h_3 - h_4)/(T_3 - T_4) = \frac{2376.82 - 1189.6}{2100 - 1124.5} = 1.217 \text{ kJ/kg-K}$$

$$k = C_P/(C_P - R) = \frac{1.217}{1.217 - 0.287} = \mathbf{1.308}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.26

Repeat Problem 10.24 using Table A.7.



Compression ratio
P_2 / P_1
Max temperature
$T_3 = 1700$ K
Combustion adds
${}_2q_3 = h_3 - h_2$

Let us work back from state 3 to 2 as

A.7: $h_3 = 1879.76$ kJ/kg

${}_2q_3 = h_3 - h_2 \quad \Rightarrow$

$h_2 = h_3 - {}_2q_3 = 1879.76 - 1000 = 879.76$ kJ/kg

From A.7: $s^o_{T2} = 7.95477$ kJ/kg-K

The compression is reversible and adiabatic so constant s. From Eq.6.19

$s^o_{T2} = s^o_{T1} + R \ln(P_2/P_1)$ so

$$P_2/P_1 = \exp\left[(s^o_{T2} - s^o_{T1})/R \right] = \exp\left[\frac{7.95477 - 6.83521}{0.287}\right] = \mathbf{49.4}$$

This is too high for a real compressor.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.27

A Brayton cycle produces net 50 MW with an inlet state of 17^{o}C, 100 kPa and the pressure ratio is 14:1. The highest cycle temperature is 1600 K. Find the thermal efficiency of the cycle and the mass flow rate of air using cold air properties.

Inlet state is state 1, $P_2/P_1 = 14$ and $T_3 = 1600$ K.
Compression: Reversible and adiabatic so constant s from Eq.6.23

$$T_2 = T_1(P_2/P_1)^{(k-1)/k} = 290 \text{ K} \times (14)^{0.2857} = 616.38 \text{ K}$$

$$\eta_{CYCLE} = w_{NET}/q_H = 1 - T_1/T_2 = 1 - \frac{290}{616.38} = \mathbf{0.5295}$$

Combustion: constant pressure

$$q_H = h_3 - h_2 = C_{P0}\,(T_3 - T_2) = 1.004 \text{ kJ/kg-K} \times (1600 - 616.38) \text{ K}$$
$$= 987.56 \text{ kJ/kg}$$

$$w_{NET} = \eta_{CYCLE}\, q_H = 0.5295 \times 987.55 \text{ kJ/kg} = 522.9 \text{ kJ/kg}$$

$$\dot{m} = \dot{W}/\, w_{NET} = 50\,000 \text{ kW} / 522.9 \text{ kJ/kg} = \mathbf{95.62 \text{ kg/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.28

A Brayton cycle produces 14 MW with an inlet state of 17°C, 100 kPa, and a compression ratio of 16:1. The heat added in the combustion is 1160 kJ/kg. What are the highest temperature and the mass flow rate of air, assuming cold air properties?
Solution:

Temperature after compression is

$$T_2 = T_1 \, r_p^{(k-1)/k} = 290 \text{ K} \times 16^{0.4/1.4} = 640.35 \text{ K}$$

The highest temperature is after combustion

$$T_3 = T_2 + q_H/C_p = 640.35 \text{ K} + \frac{1160 \text{ kJ/kg}}{1.004 \text{ kJ/kg-K}} = \mathbf{1795.7\ K}$$

Efficiency is from Eq.10.1

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 16^{-0.4/1.4} = 0.547$$

From the required power we can find the needed heat transfer

$$\dot{Q}_H = \dot{W}_{net} / \eta = \frac{14\,000}{0.547} \text{ kW} = 25\,594 \text{ kW}$$

$$\dot{m} = \dot{Q}_H / q_H = 25\,594 \text{ kW} / 1160 \text{ kJ/kg} = \mathbf{22.06\ kg/s}$$

10.29

Do Problem 10.23 using Table A.7, this becomes trial and error

Solution:

We have states 1 and 4 which mean we can find q_L and since we have efficiency $\eta = 1 - q_L/q_H$, we can find q_H.

From A.7.1: $h_1 = 290.43$ kJ/kg, $s^o_{T1} = 6.83521$ kJ/kg K

$h_4 = 686.785$ kJ/kg, $s^o_{T4} = 7.701065$ kJ/kg-K

The heat rejection becomes $q_L = h_4 - h_1 = 686.785 - 290.43 = 396.355$ kJ/kg

$q_H = q_L/(1 - \eta) = 2\, q_L =$ **792.71 kJ/kg** $= h_3 - h_2$

With a known compression ratio we can get states 2 and 4 from states 1 and 3. The compression is reversible and adiabatic so constant s. From Eq.6.19

$$s_2 = s_1 \quad \Rightarrow \quad s^o_{T2} = s^o_{T1} + R\ln(P_2/P_1) = 6.83521 + 0.287 \ln r_p$$

We get a similar relation for the expansion process

$$s_4 = s_3 \Rightarrow s^o_{T3} = s^o_{T4} + R\ln(P_3/P_4) = 7.701065 + 0.287\ln r_p$$

From the constant specific heat ($\eta = 1 - r_p^{-(k-1)/k}$ => $r_p = 11.3$) so guess $r_p = 12$

$s^o_{T2} = 6.83521 + 0.287 \ln 12 = 7.54838$ => $h_2 = 590.8$ kJ/kg

$s^o_{T3} = 7.701065 + 0.287 \ln 12 = 8.41423$ => $h_3 = 1362.44$ kJ/kg

$\Rightarrow h_3 - h_2 = 771.6$ kJ/kg which is too low (should be 792.71 kJ/kg)

Guess $r_p = 14$ and repeat the calculations

$s^o_{T2} = 6.83521 + 0.287 \ln 14 = 7.59262$ => $h_2 = 617.28$ kJ/kg

$s^o_{T3} = 7.701065 + 0.287 \ln 14 = 8.458474$ => $h_3 = 1419.76$ kJ/kg

$\Rightarrow h_3 - h_2 = 802.48$ kJ/kg which is too high (should be 792.71 kJ/kg)

Linear interpolation:

$$r_p = 12 + (14 - 12)\frac{792.71 - 771.6}{802.48 - 771.6} = \mathbf{13.37}$$

Regenerators, Intercoolers, and Non-ideal Cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.30

Would it be better to add an ideal regenerator to the Brayton cycle in problem 10.28?

Inlet state is state 1, $P_2/P_1 = 16$ and $q_H = 1160$ kJ/kg.

Compression: Reversible and adiabatic so constant s from Eq.6.23

$$T_2 = T_1(P_2/P_1)^{(k-1)/k} = 290 \text{ K} \times (16)^{0.2857} = 640.34 \text{ K}$$

Get the high temperature

$$T_3 = T_2 + q_H / C_{P0} = 640.34 \text{ K} + 1160 \text{ kJ/kg} / 1.004 \text{ kJ/kg-K} = 1795.7 \text{ K}$$

Expansion: isentropic

$$T_4 = T_3 / (P_3/P_4)^{(k-1)/k} = 1795.7 \text{ K} / 16^{0.2857} = 813.2 \text{ K} > T_2$$

Since $T_4 > T_2$ some **regeneration can be done**.

We could find (not needed), see p.471,

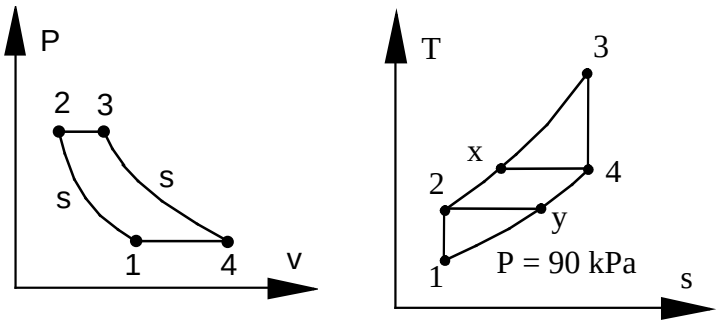
$$\eta_{CYCLE} = 1 - \frac{T_1}{T_3}(P_2/P_1)^{(k-1)/k} = 1 - T_2 / T_3 = 0.643$$

This is better than the regular cycle $\eta_{CYCLE} = 1 - r_p^{-(k-1)/k} = 0.547$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.31

A Brayton cycle with an ideal regenerator has inlet at 290 K, 90 kPa with the highest P, T as 1170 kPa, 1700 K. Find the specific heat transfer and the cycle efficiency using cold air properties.



Compression ratio
P_2 / P_1
Max temperature
$T_3 = 1700$ K
Combustion adds
$q_H = h_3 - h_x$

Let us work from state 1 to 2 as constant s, Eq.6.23

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 290\ \text{K} \times (1170/90)^{0.2857} = 603.5\ \text{K}$$

Energy equation with compressor work in

$$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 1.004(603.5 - 290) = 313.5\ \text{kJ/kg} = q_L$$

The expansion is reversible and adiabatic so constant s. From Eq.6.23

$$T_4 = T_3\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}} = 1700\ \text{K} \times \left(\frac{90}{1170}\right)^{0.2857} = \mathbf{816.9\ K} > T_2$$

Since the exhaust $T_4 > T_2$ a regenerator can be used. Now the heat transfer added is

$$q_H = h_3 - h_x = C_{P0}(T_3 - T_x) = 1.004(1700 - 816.9) = \mathbf{886.6\ kJ/kg} = w_T$$

$$\eta_{TH} = w_{NET}/q_H = (886.6 - 313.5)/\ 886.6 = \mathbf{0.646}$$

We could also have found efficiency, see p.471, as

$$\eta_{TH} = 1 - \frac{T_1}{T_3}\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 1 - \frac{T_2}{T_3} = 1 - \frac{603.5}{1700} = 0.645$$

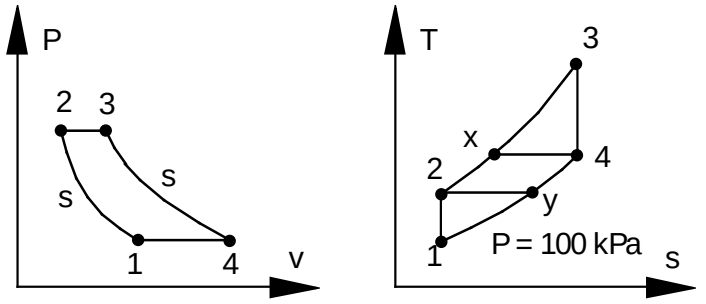
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.32

An ideal regenerator is incorporated into the ideal air-standard Brayton cycle of Problem 10.22. Find the thermal efficiency of the cycle with this modification.

Consider an ideal air-standard Brayton cycle in which the air into the compressor is at 100 kPa, 20°C, and the pressure ratio across the compressor is 12:1. The maximum temperature in the cycle is 1100°C, and the air flow rate is 10 kg/s. Assume constant specific heat for the air, value from Table A.5. Determine the compressor work, the turbine work, and the thermal efficiency of the cycle.

Solution:



Compression ratio

$$\frac{P_2}{P_1} = 12$$

Max temperature

$T_3 = 1100^{o}C$

$\dot{m} = 10$ kg/s

The compression is reversible and adiabatic so constant s. From Eq.6.23

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 293.2\ \text{K} \times (12)^{0.286} = 596.8\ \text{K}$$

Energy equation with compressor work in

$$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 1.004(596.8 - 293.2) = 304.8\ \text{kJ/kg}$$

The expansion is reversible and adiabatic so constant s. From Eq.6.23

$$T_4 = T_3\left(\frac{P_4}{P_3}\right)^{\frac{k-1}{k}} = 1373.2\ \text{K} \times \left(\frac{1}{12}\right)^{0.286} = 674.7\ \text{K}$$

Energy equation with turbine work out

$$w_T = C_{P0}(T_3 - T_4) = 1.004(1373.2 - 674.7) = 701.3\ \text{kJ/kg}$$

Ideal regenerator: $T_X = T_4 = 674.7$ K

$$q_H = h_3 - h_X = 1.004(1373.2 - 674.7) = 701.3\ \text{kJ/kg} = w_T$$

$$\eta_{TH} = w_{NET}/q_H = (701.3 - 304.8)/701.3 = \mathbf{0.565}$$

We could also have found efficiency, see p.471, as

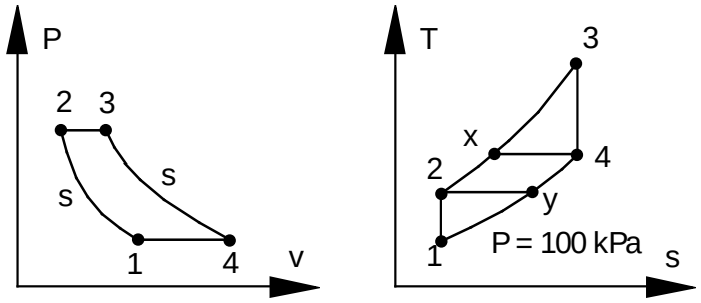
$$\eta_{TH} = 1 - \frac{T_1}{T_3}\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 1 - \frac{T_2}{T_3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.33

Consider an ideal gas-turbine cycle with a pressure ratio across the compressor of 12 to 1. The compressor inlet is at 300 K and 100 kPa, and the cycle has a maximum temperature of 1600 K. An ideal regenerator is also incorporated into the cycle. Find the thermal efficiency of the cycle using cold air (298 K) properties.

Solution:



Compression ratio

$$\frac{P_2}{P_1} = 12$$

Max temperature

$T_3 = 1600$ K

The efficiency with an ideal regenerator ($T_4 = T_x$) is from page 471

$$\eta_{TH} = 1 - \frac{T_1}{T_3}\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 1 - \frac{300}{1600} \times 12^{0.2857} = \mathbf{0.619}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.34

Assume the compressor in Problem 10.28 has an intercooler that cools the air to 330 K operating at 500 kPa followed by a second stage of compression to 1600 kPa. Find the specific heat transfer in the intercooler and the total combined work required.

Solution:

C.V. Stage 1: 1 => 2

Reversible and adiabatic gives constant s which from Eq.6.23 gives:

$$T_2 = T_1 (P_2/P_1)^{(k-1)/k} = 290 \text{ K} \times (500/100)^{0.2857} = 459.3 \text{ K}$$

$$w_{c1in} = C_P(T_2 - T_1) = 1.004(459.3 - 290) = 187.0 \text{ kJ/kg}$$

CV. Intercooler 2 => 3

Constant pressure cooling

$$q_{out} = h_2 - h_3 = C_P (T_2 - T_3) = 1.004 (459.3 - 330) = \mathbf{129.8\ kJ/kg}$$

C.V. Stage 2: 3 => 4

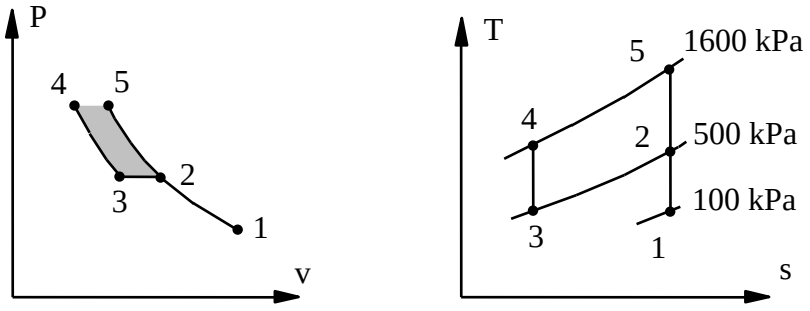
Reversible and adiabatic gives constant s which from Eq.6.23 gives:

$$T_4 = T_3 (P_4/P_3)^{(k-1)/k} = 330 \text{ K} \times (1600/500)^{0.2857} = 460.1 \text{ K}$$

$$w_{c2in} = C_P(T_4 - T_3) = 1.004(460.1 - 330) = 130.6 \text{ kJ/kg}$$

$$w_{tot} = w_{c1} + w_{c2} = 187 + 130.6 = \mathbf{318\ kJ/kg}$$

The intercooler reduces the work for stage 2 as T is lower and so is specific volume. The reduction in work due to the intercooler is shaded in the P-v diagram.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.35

A two-stage air compressor has an intercooler between the two stages as shown in Fig. P10.35. The inlet state is 100 kPa, 290 K, and the final exit pressure is 1.6 MPa. Assume that the constant pressure intercooler cools the air to the inlet temperature, $T_3 = T_1$. It can be shown that the optimal pressure, $P_2 = (P_1 P_4)^{1/2}$, for minimum total compressor work. Find the specific compressor works and the intercooler heat transfer for the optimal P_2.

Solution:

Optimal intercooler pressure $P_2 = \sqrt{100 \times 1600} = 400$ kPa

1: $h_1 = 290.43$ kJ/kg, $s^o_{T1} = 6.83521$ kJ/kg K

C.V. C1: $w_{C1} = h_2 - h_1$, $s_2 = s_1$ leading to Eq.6.19

$\Rightarrow \quad s^o_{T2} = s^o_{T1} + R \ln(P_2/P_1) = 6.83521 + 0.287 \ln 4 = 7.2331$ kJ/kg K

$\Rightarrow T_2 = 430.3$ K, $h_2 = 432.05$ kJ/kg

$w_{C1} = 432.05 - 290.43 =$ **141.6 kJ/kg**

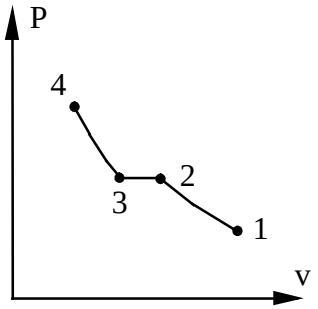
C.V. Cooler: $T_3 = T_1 \Rightarrow h_3 = h_1$

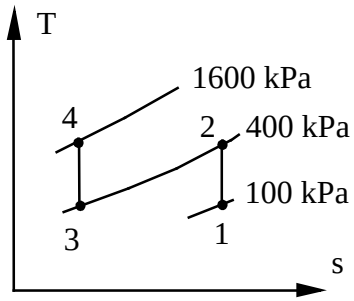
$q_{OUT} = h_2 - h_3 = h_2 - h_1 = w_{C1} =$ **141.6 kJ/kg**

C.V. C2: $T_3 = T_1$, $s_4 = s_3$ and since $s^o_{T3} = s^o_{T1}$, $P_4/P_3 = P_2/P_1$

$\Rightarrow \quad s^o_{T4} = s^o_{T3} + R \ln(P_4/P_3) = s^o_{T2}$, so we have $T_4 = T_2$

Thus we get $w_{C2} = w_{C1} =$ **141.6 kJ/kg**





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.36

The gas-turbine cycle shown in Fig. P10.36 is used as an automotive engine. In the first turbine, the gas expands to pressure P_5, just low enough for this turbine to drive the compressor. The gas is then expanded through the second turbine connected to the drive wheels. The data for the engine are shown in the figure and assume that all processes are ideal. Determine the intermediate pressure P_5, the net specific work output of the engine, and the mass flow rate through the engine. Find also the air temperature entering the burner T_3, and the thermal efficiency of the engine.

a) Consider the compressor

$$s_2 = s_1 \Rightarrow T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300\ \text{K} \times (6)^{0.286} = 500.8\ \text{K}$$

$$-w_C = -w_{12} = C_{P0}(T_2 - T_1) = 1.004(500.8 - 300) = 201.6\ \text{kJ/kg}$$

Consider then the first turbine work

$$w_{T1} = -w_C = 201.6\ \text{kJ/kg} = C_{P0}(T_4 - T_5) = 1.004\ \text{kJ/kg-K}\ (1600\ \text{K} - T_5)$$

$$\Rightarrow T_5 = 1399.2\ \text{K}$$

$$s_5 = s_4 \Rightarrow \quad P_5 = P_4\left(\frac{T_5}{T_4}\right)^{\frac{k}{k-1}} = 600\ \text{kPa} \times \left(\frac{1399.2}{1600}\right)^{3.5} = \mathbf{375\ kPa}$$

b) $$s_6 = s_5 \Rightarrow T_6 = T_5\left(\frac{P_6}{P_5}\right)^{\frac{k-1}{k}} = 1399.2\ \text{K} \times \left(\frac{100}{375}\right)^{0.286} = 958.8\ \text{K}$$

The second turbine gives the net work out

$$w_{T2} = C_{P0}(T_5 - T_6) = 1.004(1399.2 - 958.8) = 442.2\ \text{kJ/kg}$$

$$\dot{m} = \dot{W}_{NET}/w_{T2} = 150/442.2 = \mathbf{0.339\ kg/s}$$

c) Ideal regenerator $\Rightarrow$ $T_3 = T_6 = \mathbf{958.8\ K}$

$$q_H = C_{P0}(T_4 - T_3) = 1.004\ \text{kJ/kg-K}\ (1600 - 958.8)\ \text{K} = 643.8\ \text{kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = 442.2/643.8 = \mathbf{0.687}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.37

Repeat Problem 10.35 when the intercooler brings the air to $T_3 = 320$ K. The corrected formula for the optimal pressure is $P_2 = [\, P_1 P_4 \, (T_3/T_1)^{n/(n-1)}]^{1/2}$ see Problem 7.245, where *n* is the exponent in the assumed polytropic process.

Solution:

The polytropic process has n = k (isentropic) so $n/(n - 1) = 1.4/0.4 = 3.5$

$$P_2 = [\, P_1 P_4 \, (T_3/T_1)^{n/(n-1)}]^{1/2}$$

$$= \sqrt{100 \times 1600}\ \text{kPa}\ \sqrt{(320/290)^{3.5}} = 475.2\ \text{kPa}$$

C.V. C1: $s_2 = s_1 \Rightarrow T_2 = T_1 \, (P_2/P_1)^{\frac{k-1}{k}} = 290\ \text{K} \times (475.2/100)^{0.2857} = 452.67\ \text{K}$

$$w_{C1} = h_2 - h_1 = C_p(T_2 - T_1) = 1.004\ \text{kJ/kg-K} \times (452.67 - 290)\ \text{K}$$

$$= \mathbf{163.3\ kJ/kg}$$

C.V. Cooler: $q_{OUT} = h_2 - h_3 = 1.004\ \text{kJ/kg-K}\ (452.67 - 320)\ \text{K} = \mathbf{133.2\ kJ/kg}$

C.V. C2: $s_4 = s_3 \Rightarrow T_4 = T_3 \, (P_4/P_3)^{\frac{k-1}{k}} = 320\ \text{K} \times (1600/475.2)^{0.2857} = 452.67\ \text{K}$

$$w_{C2} = h_4 - h_3 = C_p(T_2 - T_1) = 1.004\ \text{kJ/kg-K}\ (452.67 - 320)\ \text{K}$$

$$= \mathbf{133.2\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.38

Repeat Problem 10.21, but include a regenerator with 75% efficiency in the cycle.

A large stationary Brayton cycle gas-turbine power plant delivers a power output of 100 MW to an electric generator. The minimum temperature in the cycle is 300 K, and the exhaust temperature is 750 K. The minimum pressure in the cycle is 100 kPa, and the compressor pressure ratio is 14 to 1. Calculate the power output of the turbine. What fraction of the turbine output is required to drive the compressor? What is the thermal efficiency of the cycle?

Solution:

Both compressor and turbine are reversible and adiabatic so constant s, Eq.6.23 relates then T to P assuming constant heat capacity.

Compressor: $\Rightarrow T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 300\ \text{K}\ (14)^{0.286} = 638.1\ \text{K}$

$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 1.004\ (638.1 - 300) = 339.5\ \text{kJ/kg}$

Turbine $s_4 = s_3 \Rightarrow T_3 = T_4\,(P_3/P_4)^{\frac{k-1}{k}} = 750\ \text{K} \times (14)^{0.286} = 1594\ \text{K}$

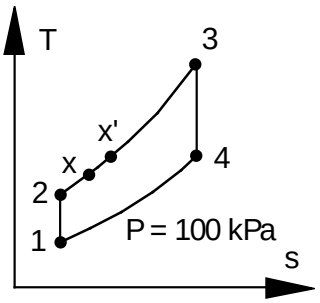
$w_T = h_3 - h_4 = C_{P0}(T_3 - T_4) = 1.004\ (1594 - 750) = 847.4\ \text{kJ/kg}$

$w_{NET} = 847.4 - 339.5 = 507.9\ \text{kJ/kg}$

$\dot{m} = \dot{W}_{NET}/w_{NET} = 100\,000\ \text{kW}\ /507.9\ \text{kJ/kg} = 196.9\ \text{kg/s}$

$\dot{W}_T = \dot{m}w_T = 196.9\ \text{kg/s} \times 847.4\ \text{kJ/kg} =$ **166.85 MW**

$w_C/w_T = 339.5/847.4 =$ **0.40**



For the regenerator

$$\eta_{REG} = 0.75 = \frac{h_X - h_2}{h_{X'} - h_2} = \frac{T_X - T_2}{T_4 - T_2} = \frac{T_X - 638.1}{750 - 638.1}$$

$$\Rightarrow T_X = 722.0\ \text{K}$$

Turbine and compressor work not affected by regenerator.

Combustor needs to add less energy with the regenerator as

$q_H = C_{P0}(T_3 - T_X) = 1.004(1594 - 722) = 875.5\ \text{kJ/kg}$

$\eta_{TH} = w_{NET}/q_H = 507.9/875.5 =$ **0.58**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.39

An air compressor has inlet of 100 kPa, 290 K and brings it to 500 kPa after which the air is cooled in an intercooler to 340 K by heat transfer to the ambient 290 K. Assume this first compressor stage has an isentropic efficiency of 85% and it is adiabatic. Using constant specific heat and find the compressor exit temperature and the specific entropy generation in the process.

C.V.: Stage 1 air, Steady flow

Isentropic compressor is done first.

Process: adiabatic: q = 0, reversible: $s_{gen} = 0$

Energy Eq.6.13: $-w_{C1} = h_2 - h_1$, Entropy Eq.9.8: $s_2 = s_1$

Assume constant $C_{P0} = 1.004$ from A.5 and isentropic leads to Eq.6.23

$$T_{2s} = T_1(P_2/P_1)^{\frac{k-1}{k}} = 290\ \text{K} \times (500/100)^{0.286} = 459.3\ \text{K}$$

$$w_{C1s} = h_1 - h_{2s} = C_{Po}(T_1 - T_2) = 1.004(290 - 459.3) = -170\ \text{kJ/kg}$$

Now the **actual compressor** work becomes

$$w_{C1\,ac} = w_{C1s}/\eta_{C1s} = -170/0.85 = -200\ \text{kJ/kg} = h_1 - h_{2ac} = C_{Po}(T_1 - T_{2ac})$$

$$T_{2ac} = T_1 - w_{C1\,ac}/C_{Po} = 290 + 200/1.004 = \mathbf{489.2\ K}$$

$$s_{gen} = s_{2ac} - s_1 = C_{Po} \ln\left(\frac{T_{2ac}}{T_1}\right) - R \ln\left(\frac{P_2}{P_1}\right)$$

$$= 1.004 \ln(489.2/290) - 0.287(500/100) = \mathbf{0.0631\ kJ/kg\text{-}K}$$

10.40

A two-stage compressor in a gas turbine brings atmospheric air at 100 kPa, 17°C to 500 kPa, then cools it in an intercooler to 27°C at constant P. The second stage brings the air to 2500 kPa. Assume both stages are adiabatic and reversible. Find the combined specific work to the compressor stages. Compare that to the specific work for the case of no intercooler (i.e. one compressor from 100 to 1000 kPa).

Solution:

C.V. Stage 1: 1 => 2

Reversible and adiabatic gives constant s which from Eq.6.23 gives:

$$T_2 = T_1 (P_2/P_1)^{(k-1)/k} = 290 \text{ K } (500/100)^{0.2857} = 459.3 \text{ K}$$

$$w_{c1in} = C_P(T_2 - T_1) = 1.004(459.3 – 290) = 170.0 \text{ kJ/kg}$$

C.V. Stage 2: 3 => 4

Reversible and adiabatic gives constant s which from Eq.6.23 gives:

$$T_4 = T_3 (P_4/P_3)^{(k-1)/k} = 300 \text{ K } (2500/500)^{0.2857} = 475.1 \text{ K}$$

$$w_{c2in} = C_P(T_4 - T_3) = 1.004 \text{ kJ/kg-K } (475.1 – 300) \text{ K} = 175.8 \text{ kJ/kg}$$

$$w_{tot} = w_{c1} + w_{c2} = 170 + 175.8 = \mathbf{345.8 \text{ kJ/kg}}$$

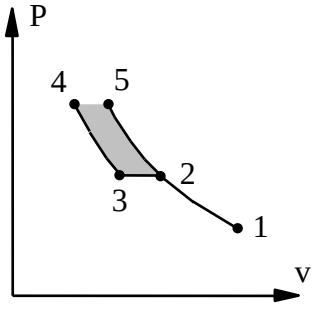
The intercooler reduces the work for stage 2 as T is lower and so is specific volume.

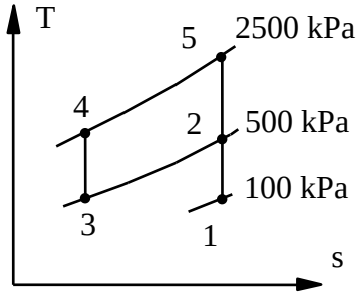
C.V. One compressor 1 => 5

Reversible and adiabatic gives constant s which from Eq.6.23 gives:

$$T_5 = T_1 (P_5/P_1)^{(k-1)/k} = 290 \text{ K } (2500/100)^{0.2857} = 727.4 \text{ K}$$

$$w_{in} = C_P(T_5 - T_1) = 1.004 \text{ kJ/kg-K } (727.4 – 290) \text{ K} = \mathbf{439 \text{ kJ/kg}}$$





The reduction in work due to the intercooler is shaded in the P-v diagram.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.41

Repeat Problem 10.21, but assume that the compressor has an isentropic efficiency of 85% and the turbine an isentropic efficiency of 88%.

Solution:

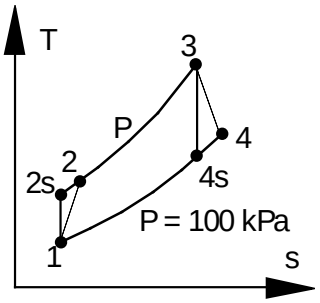
The original cycle was reversible Brayton cycle so this means:

Minimum T: $T_1 = 300$ K

Exhaust T: $T_{4s} = 750$ K

Pressure ratio: $P_2/P_1 = 14$

Solve using constant C_{P0}



Ideal compressor: $s_2 = s_1 \Rightarrow$ Implemented in Eq.6.23

$$T_{2s} = T_1(P_2/P_1)^{\frac{k-1}{k}} = 300 \text{ K } (14)^{0.286} = 638.1 \text{ K}$$

$$w_{Cs} = h_2 - h_1 = C_{P0}(T_2 - T_1) = 1.004\ (638.1 - 300) = 339.5 \text{ kJ/kg}$$

Actual compressor

$$\Rightarrow w_C = w_{SC}/\eta_{SC} = 339.5/0.85 = 399.4 \text{ kJ/kg} = C_{P0}(T_2 - T_1)$$

$$\Rightarrow T_2 = T_1 + w_c/C_{P0} = 300 + 399.4/1.004 = 697.8 \text{ K}$$

Ideal turbine: $s_4 = s_3 \Rightarrow$ Implemented in Eq.6.23

$$T_3 = T_{4s}\,(P_3/P_{4s})^{\frac{k-1}{k}} = 750 \text{ K } (14/1)^{0.286} = 1594 \text{ K}$$

$$w_{Ts} = h_3 - h_4 = C_{P0}(T_3 - T_4) = 1.004\ (1594 - 750) = 847.4 \text{ kJ/kg}$$

Actual turbine

$$\Rightarrow w_T = \eta_{ST}\ w_{ST} = 0.88 \times 847.4 = 745.7 \text{ kJ/kg} = C_{P0}(T_3 - T_4)$$

$$\Rightarrow T_4 = T_3 - w_T/C_{P0} = 1594 - 745.7/1.004 = 851.3 \text{ K}$$

Do the overall net and cycle efficiency

$$w_{NET} = w_T - w_C = 745.7 - 399.4 = 346.3 \text{ kJ/kg}$$

$$\dot{m} = \dot{W}_{NET}/w_{NET} = 100000 \text{ kW } /346.3 \text{ kJ/kg} = 288.8 \text{ kg/s}$$

$$\dot{W}_T = \dot{m} w_T = 288.8 \text{ kg/s} \times 745.7 \text{ kJ/kg} = \mathbf{215.36\ MW}$$

$$w_C/w_T = 399.4/745.7 = \mathbf{0.536}$$

Energy input is from the combustor

$$q_H = C_{P0}(T_3 - T_2) = 1.004 \text{ kJ/kg-K } (1594 - 697.8) \text{ K} = 899.8 \text{ kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = 346.3/899.8 = \mathbf{0.385}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.42

A gas turbine with air as the working fluid has two ideal turbine sections, as shown in Fig. P10.42, the first of which drives the ideal compressor, with the second producing the power output. The compressor input is at 290 K, 100 kPa, and the exit is at 450 kPa. A fraction of flow, *x*, bypasses the burner and the rest (1 – *x*) goes through the burner where 1200 kJ/kg is added by combustion. The two flows then mix before entering the first turbine and continue through the second turbine, with exhaust at 100 kPa. If the mixing should result in a temperature of 1000 K into the first turbine find the fraction *x*. Find the required pressure and temperature into the second turbine and its specific power output.

C.V.Comp.: $-w_C = h_2 - h_1$; $s_2 = s_1$

Reversible and adiabatic gives constant s which from Eq.6.23 gives:

$$T_2 = T_1 (P_2/P_1)^{(k-1)/k} = 290 \text{ K } (450/100)^{0.2857} = 445.7 \text{ K}$$

$$h_2 = 447.75 \text{ kJ/kg}, \quad -w_C = 447.75 - 290.43 = 157.3 \text{ kJ/kg}$$

C.V.Burner: $h_3 = h_2 + q_H = 447.75 + 1200 = 1647.75$ kJ/kg

$$\Rightarrow T_3 = 1510 \text{ K}$$

C.V.Mixing chamber: $(1 - x)h_3 + xh_2 = h_{MIX} = 1046.22$ kJ/kg

$$x = \frac{h_3 - h_{MIX}}{h_3 - h_2} = \frac{1647.75 - 1046.22}{1647.75 - 447.75} = \mathbf{0.5013}$$

$$\dot{W}_{T1} = \dot{W}_{C,in} \Rightarrow w_{T1} = -w_C = 157.3 = h_3 - h_4$$

$$h_4 = 1046.22 - 157.3 = 888.9 \text{ kJ/kg} \Rightarrow T_4 = \mathbf{860 \text{ K}}$$

$$P_4 = P_{MIX}(T_4/T_{MIX})^{k/(k-1)} = 450 \text{ kPa} \times (860/1000)^{3.5} = \mathbf{265 \text{ kPa}}$$

$$s_4 = s_5 \Rightarrow T_5 = T_4 (P_5/P_4)^{(k-1)/k} = 860 \text{ K } (100/265)^{0.2857} = 651 \text{ K}$$

$$h_5 = 661.2 \text{ kJ/kg}$$

$$w_{T2} = h_4 - h_5 = 888.9 - 661.2 = \mathbf{227.7 \text{ kJ/kg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.43

A gas turbine cycle has two stages of compression, with an intercooler between the stages. Air enters the first stage at 100 kPa, 300 K. The pressure ratio across each compressor stage is 4 to 1, and each stage has an isentropic efficiency of 82%. Air exits the intercooler at 330 K. Calculate the temperature at the exit of each compressor stage and the total specific work required.

Solution:

State 1: $P_1 = 100$ kPa, $T_1 = 300$ K

State 3: $T_3 = 330$ K

$P_2 = 4\ P_1 = 400$ kPa; $\quad P_4 = 4\ P_3 = 1600$ kPa

Energy Eq.: $w_{c1} + h_1 = h_2 \quad \Rightarrow \quad w_{c1} = h_2 - h_1 \approx C_P(T_2 - T_1)$

Ideal C1 constant s, Eq.6.23: $\quad T_{2s} = T_1\ (P_2/P_1)^{(k-1)/k} = 445.8$ K

$w_{c1\ s} = h_{2s} - h_1 \approx C_P(T_{2s} - T_1) = 146.4$ kJ/kg,

Actual Eq.7.28: $\quad w_{c1} = w_{c1\ s}/\eta = 146.4/0.82 = 178.5$ kJ/kg

$T_2 = T_1 + w_{c1}/C_P =$ **477.8 K**

Ideal C2 constant s, Eq.6.23: $\quad T_{4s} = T_3\ (P_4/P_3)^{(k-1)/k} = 490.4$ K

$w_{c2\ s} = h_{4s} - h_3 \approx C_P(T_{4s} - T_3) = 161$ kJ/kg;

Actual Eq.7.28: $\quad w_{c2} = w_{c2\ s}/\eta = 196.4$ kJ/kg

$T_4 = T_3 + w_{c2} / C_P =$ **525.6 K**

Total work in:

$w = w_{c1} + w_{c2} = 178.5 + 196.4 =$ **374.9 kJ/kg**

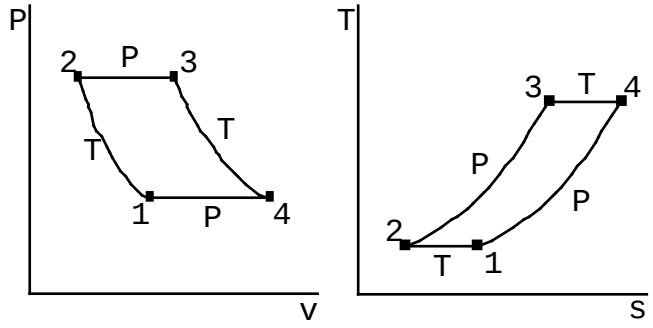
10.44

Consider an ideal air-standard Ericsson cycle that has an ideal regenerator as shown in Fig. P10.44. The high pressure is 1.5 MPa and the cycle efficiency is 60%. Heat is rejected in the cycle at a temperature of 350 K, and the cycle pressure at the beginning of the isothermal compression process is 150 kPa. Determine the high temperature, the compressor work, and the turbine work per kilogram of air.



$P_2 = P_3 = 1.5$ MPa

$T_1 = T_2 = 350$ K

$P_1 = 150$ kPa

${}_2q_3 = -{}_4q_1$ (ideal reg.)

$\Rightarrow q_H = {}_3q_4$ & $w_T = q_H$

$r_p = P_2/P_1 = 10$

$\eta_{TH} = \eta_{CARNOT\ TH.} = 1 - T_L/T_H = 0.6 \Rightarrow T_3 = T_4 = T_H =$ **875 K**

$$q_L = w_C = \int v\, dP = RT_1 \ln\left(\frac{P_2}{P_1}\right) = 0.287 \times 350 \times \ln\left(\frac{1500}{150}\right) = \textbf{231.3 kJ/kg}$$

$w_T = q_H = -\int v\, dP = -RT_3 \ln(P_4/P_3) =$ **578.2 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.45

An air-standard Ericsson cycle has an ideal regenerator. Heat is supplied at 1000°C and heat is rejected at 80°C. Pressure at the beginning of the isothermal compression process is 70 kPa. The heat added is 700 kJ/kg. Find the compressor work, the turbine work, and the cycle efficiency.

Solution:

Identify the states

Heat supplied at high temperature $T_3 = T_4 = 1000°C = 1273.15$ K

Heat rejected at low temperature $T_1 = T_2 = 80°C = 353.15$ K

Beginning of the compression: $P_1 = 70$ kPa

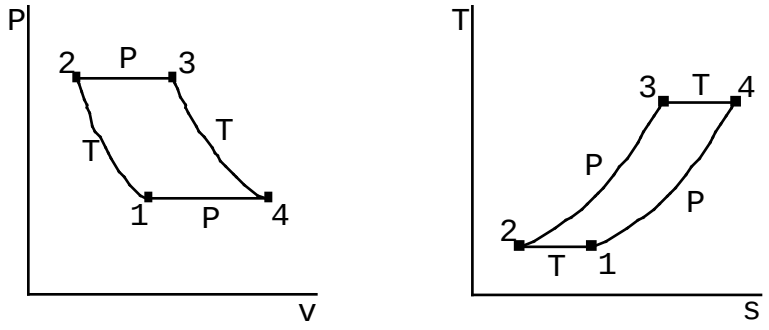
Ideal regenerator: ${}_2q_3 = -{}_4q_1 \quad \Rightarrow \quad q_H = {}_3q_4 = 700$ kJ/kg

$$\Rightarrow \quad w_T = q_H = \mathbf{700\ kJ/kg}$$

$$\eta_{TH} = \eta_{CARNOT} = 1 - \frac{353.15}{1273.15} = \mathbf{0.7226}$$

$$w_{NET} = \eta_{TH}\, q_H = 0.7226 \times 700 = 505.8 \text{ kJ/kg}$$

$$w_C = q_L = q_H - w_{NET} = 700 - 505.8 = \mathbf{194.2\ kJ/kg}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Jet Engine Cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.46

The Brayton cycle in Problem 10.21 is changed to be a jet engine. Find the exit velocity using cold air properties.

A large stationary Brayton cycle gas-turbine power plant delivers a power output of 100 MW to an electric generator. The minimum temperature in the cycle is 300 K, and the exhaust temperature is 750 K. The minimum pressure in the cycle is 100 kPa, and the compressor pressure ratio is 14 to 1. Calculate the power output of the turbine. What fraction of the turbine output is required to drive the compressor? What is the thermal efficiency of the cycle?

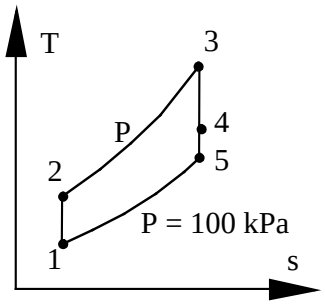
Solution:

Brayton cycle so this means:

Minimum T: $T_1 = 300$ K

Exhaust T: $T_5 = 750$ K

Pressure ratio: $P_2/P_1 = 14$



Solve using constant C_{P0}

Compression in compressor: $s_2 = s_1 \Rightarrow$ Implemented in Eq.6.23

$$T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 300 \text{ K } (14)^{0.286} = 638.1 \text{ K}$$

$$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 1.004 \text{ kJ/kg-K } (638.1 - 300) \text{ K} = 339.5 \text{ kJ/kg}$$

Turbine ($w_T = w_C$) and nozzle: $s_5 = s_4 = s_3 \Rightarrow$ Implemented in Eq.6.23

$$T_3 = T_5 (P_3/P_5)^{\frac{k-1}{k}} = 750 \text{ K } (14/1)^{0.286} = 1594 \text{ K}$$

$$h_3 - h_5 = C_{P0}(T_3 - T_5) = 1.004 \text{ kJ/kg-K } (1594 - 750) \text{ K} = 847.4 \text{ kJ/kg}$$

$$1/2\mathbf{V}_5^2 = h_3 - h_5 - w_C = 847.4 - 339.5 = 507.9 \text{ kJ/kg}$$

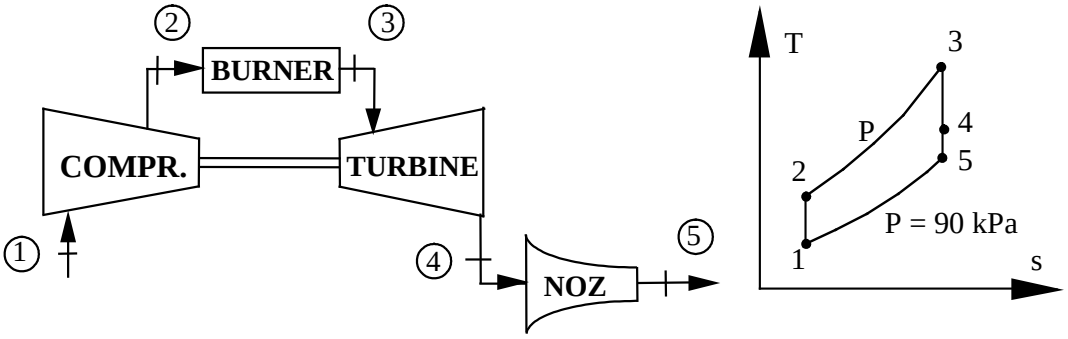
$$\mathbf{V}_5 = \sqrt{2 \times 1000 \text{ J/kJ} \times 507.9 \text{ kJ/kg}} = \mathbf{1008 \text{ m/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.47

Consider an ideal air-standard cycle for a gas-turbine, jet propulsion unit, such as that shown in Fig. 10.9. The pressure and temperature entering the compressor are 90 kPa, 290 K. The pressure ratio across the compressor is 14 to 1, and the turbine inlet temperature is 1500 K. When the air leaves the turbine, it enters the nozzle and expands to 90 kPa. Determine the velocity of the air leaving the nozzle.

Solution:



C.V. Compressor: Reversible and adiabatic $s_2 = s_1$ From Eq.6.20, 6.23

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 290\ \text{K}\ (14)^{0.2857} = 616.4\ \text{K}$$

$$w_C = h_2 - h_1 \approx C_{P0}\,(T_2 - T_1) = 1.004\ \text{kJ/kg-K} \times (616.4 - 290)\ \text{K} = 327.7\ \text{kJ/kg}$$

C.V. Turbine: $w_T = h_3 - h_4 = w_C$ and $s_4 = s_3 \Rightarrow$

$$T_4 = T_3 - w_C/C_{P0} = 1500 - 327.7/1.004 = 1173.6\ \text{K}$$

C.V. Nozzle: $s_5 = s_4 = s_3$ so from Eq.6.23

$$T_5 = T_3\left(\frac{P_5}{P_3}\right)^{\frac{k-1}{k}} = 1500\ \text{K} \times \left(\frac{90}{1260}\right)^{0.2857} = 705.7\ \text{K}$$

Now the energy equation

$$(1/2)\mathbf{V}_5^2 = h_4 - h_5 \approx C_{P0}\,(T_4 - T_5) = 1.004\ (1173.6 - 705.7) = 469.77\ \text{kJ/kg}$$

$$\Rightarrow \quad \mathbf{V}_5 = \sqrt{2 \times 1000\ \text{J/kJ} \times 469.77\ \text{kJ/kg}} = \mathbf{969\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.48

The turbine section in a jet engine receives gas (assume air) at 1200 K, 800 kPa with an ambient atmosphere at 80 kPa. The turbine is followed by a nozzle open to the atmosphere and all the turbine work drives a compressor. Find the turbine exit pressure so the nozzle has an exit velocity of 800 m/s. Hint: take the CV around both turbine and nozzle.

Solution:

C.V. Reversible and adiabatic turbine and nozzle. This gives constant s, from Eq.6.23 we can relate the T's and P's

State 3: 1200 K, 800 kPa State 5: 80 kPa; $s_5 = s_3$

Eq.6.23: $T_5 = T_3 (P_5/P_3)^{(k-1)/k} = 1200 \text{ K } (80/800)^{0.2857} = 621.56 \text{ K}$

Energy: $h_3 + 0 = h_5 + (1/2)\mathbf{V}_5^2 + w_T = h_4 + w_T$

$$w_T = h_3 - h_5 - (1/2)\mathbf{V}_5^2 \cong C_P(T_3 - T_5) - (1/2)\mathbf{V}_3^2$$

$$= 1.004 \text{ kJ/kg-K } (1200 - 621.56) \text{ K} - (1/2) \times 800^2 \text{(J/kg)} / (1000 \text{ J/kJ})$$

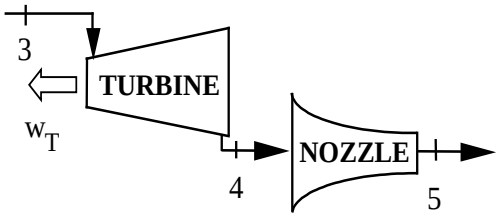
$$= 580.75 - 320 = 260.75 \text{ kJ/kg}$$

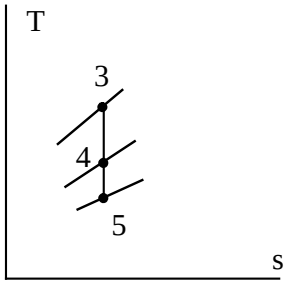
C.V. Nozzle alone to establish state 4 (same s as state 5 and 3).

$$h_4 = h_5 + (1/2)\mathbf{V}_5^2 = h_3 - w_T$$

$$T_4 = T_5 + (1/2)\mathbf{V}_5^2/C_P = 621.56 + 320/1.004 = 940.29 \text{ K}$$

$$P_4 = P_3 (T_4/T_3)^{k/(k-1)} = 800 \text{ kPa} \times (940.29/1200)^{3.5} = \mathbf{340.7 \text{ kPa}}$$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.49

Given the conditions in the previous problem what pressure could an ideal compressor generate (not the 800 kPa but higher).

C.V. Reversible and adiabatic turbine and nozzle. This gives constant s, from Eq.6.23 we can relate the T's and P's

State 3: 1200 K, 800 kPa State 5: 80 kPa; $s_5 = s_3$

Eq.6.23: $T_5 = T_3 (P_5/P_3)^{(k-1)/k} = 1200 \text{ K } (80/800)^{0.2857} = 621.56 \text{ K}$

Energy: $h_3 + 0 = h_5 + (1/2)\mathbf{V}_5^2 + w_T = h_4 + w_T$

$$w_T = h_3 - h_5 - (1/2)\mathbf{V}_5^2 \cong C_P(T_3 - T_5) - (1/2)\mathbf{V}_3^2$$

$$= 1.004(1200 - 621.56) - (1/2) \times 800^2/1000$$

$$= 580.75 - 320 = 260.75 \text{ kJ/kg}$$

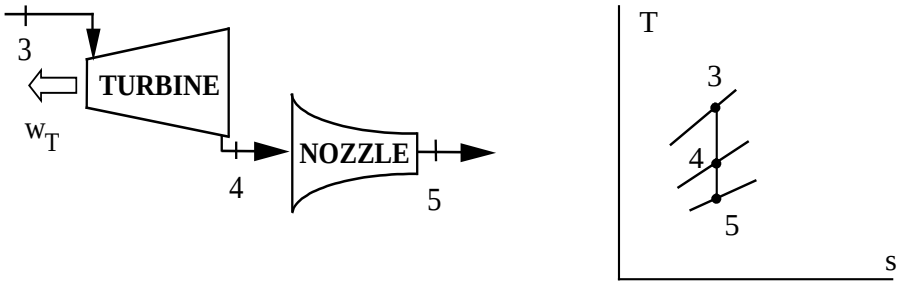
C.V. Compressor

$$w_c = h_2 - h_1 = w_T = 260.75 \text{ kJ/kg}$$

$$T_2 = T_1 + w_c/C_P = 270 \text{ K} + 260.75 \text{ kJ/kg} / 1.004 \text{ kJ/kg-K} = 529.71 \text{ K}$$

Reversible adiabatic compressor, constant s gives relation in Eq.6.23

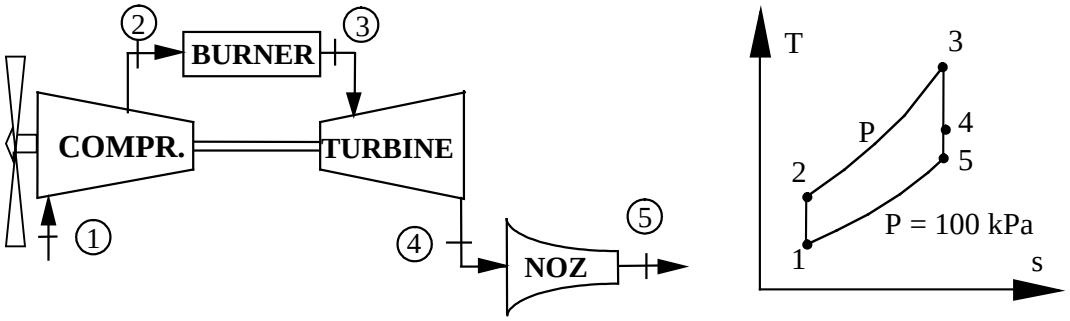
$$P_2 = P_1 \times (T_2/T_1)^{k/(k-1)} = 85 \text{ kPa} \times (529.71/270)^{3.5} = \mathbf{899 \text{ kPa}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.50

Consider a turboprop engine where the turbine powers the compressor and a propeller. Assume the same cycle as in Problem 10.46 with a turbine exit temperature of 900 K. Find the specific work to the propeller and the exit velocity.



Compression in compressor: $s_2 = s_1 \Rightarrow$ Implemented in Eq.6.23

$$T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 300 \text{ K} \times (14)^{0.286} = 638.1 \text{ K}$$

$$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 1.004 \text{ kJ/kg-K } (638.1 - 300) \text{ K} = 339.5 \text{ kJ/kg}$$

C.V. Turbine: $w_T = h_3 - h_4 = w_C + w_{prop}$ and $s_4 = s_3 = s_5 \Rightarrow$

$$T_3 = T_5 (P_3/P_5)^{\frac{k-1}{k}} = 750 \text{ K} \times (14/1)^{0.286} = 1594 \text{ K}$$

$$w_{prop} = C_{P0} (T_3 - T_4) - w_C = 1.004(1594 - 900) - 339.5 = \mathbf{357.3\ kJ/kg}$$

C.V. Nozzle: $s_5 = s_4 = s_3$ so from Eq.6.23

Now the energy equation

$$(1/2)\mathbf{V}_5^2 = h_4 - h_5 \approx C_{P0} (T_4 - T_5) = 1.004 (900 - 750) = 150.6 \text{ kJ/kg}$$

$$\Rightarrow \quad \mathbf{V}_5 = \sqrt{2 \times 1000 \times 150.6} = \mathbf{549\ m/s}$$

10.51

Consider an air standard jet engine cycle operating in a 280 K, 100 kPa environment. The compressor requires a shaft power input of 4000 kW. Air enters the turbine state 3 at 1600 K, 2 MPa, at the rate of 9 kg/s, and the isentropic efficiency of the turbine is 85%. Determine the pressure and temperature entering the nozzle at state 4. If the nozzle efficiency is 95%, determine the temperature and velocity exiting the nozzle at state 5.

Solution:

C.V. Shaft: $\dot{W}_T = \dot{m}(h_3 - h_4) = \dot{W}_C$

CV Turbine: $h_3 - h_4 = \dot{W}_C / \dot{m} = 4000 \text{ kW} / 9 \text{ kg/s} = 444.4 \text{ kJ/kg}$

$T_4 = T_3 - w_{Ta}/ C_p = 1600 - 444.4/1.004 = 1157.4 \text{ K}$

Work back to the ideal turbine conditions

Eq.7.27: $w_{Ts} = w_{Ta} / \eta = 444.4/0.85 = 522.82 = h_3 - h_{4s} = C_p(T_3 - T_{4s})$

$\Rightarrow \quad T_{4s} = 1600 - 522.82/1.004 = 1079.3 \text{ K},$

$P_4 = P_3 (T_{4s}/T_3)^{k/(k-1)} = 2000 \text{ kPa} \times (1079.3/1600)^{3.5} =$ **504.2 kPa**

C.V. Nozzle: First the ideal (reversible and adiabatic i.e. constant s, Eq.6.23)

$\Rightarrow T_{5s} = T_4 (P_5/P_4)^{(k-1)/k} = 1157.4 \text{ K} \times (100/504.2)^{(k-1)/k} = 729 \text{ K}$

Energy Eq.: $(1/2)\mathbf{V}_{5s}^2 = h_4 - h_{5s} = C_p(T_4 - T_{5s})$

$= 1.004 \text{ kJ/kg-K} \times (1157.4 - 729) \text{ K} = 430.1 \text{ kJ/kg}$

Now consider the actual nozzle

Eq.7.30: $0.5\mathbf{V}_{5a}^2 = \eta(0.5\mathbf{V}_{5s}^2) = 408.6 \text{ kJ/kg}$

$\Rightarrow \quad \mathbf{V}_{5a} = \sqrt{2 \times 1000 \text{ J/kJ} \times 408.6 \text{ kJ/kg}} =$ **904 m/s**

$T_{5a} = T_4 - 0.5\mathbf{V}_{5a}^2/C_p = 1157.4 - 408.6 / 1.004 =$ **750 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.52

Solve the previous problem using the air tables.

Solution done with the air tables A.7:

C.V. Shaft: $\dot{W}_T = \dot{m}(h_3 - h_4) = \dot{W}_C$

CV Turbine: $h_3 - h_4 = \dot{W}_C / \dot{m} = 4000/9 = 444.4$ kJ/kg

$h_4 = 1757.3 - 444.4 = 1312.9$ kJ/kg

Work back to the ideal turbine conditions

Eq.7.27: $w_{Ta} = w_C = 444.4 \quad \Rightarrow \quad w_{Ts} = w_{Ta} / \eta = 522.82 = h_3 - h_{4s}$

$h_{4s} = 1234.5 \quad \Rightarrow \quad T_{4s} \approx 1163$ K, $\quad s^o_{T4s} = 8.3091$ kJ/kg K

$s_{4s} - s_3 = 0 = s^o_{T4s} - s^o_{T3} - R \ln(P_4/P_3)$

$0 = 8.3091 - 8.6905 - 0.287 \ln(P_4/2000) \quad \Rightarrow \quad \mathbf{P_4 = 530\ kPa}$

State 4 from A.7.1: $h_4 = 1312.9$, $\quad T_4 = 1229.8$ K, $\quad s^o_{T4} = 8.3746$ kJ/kg K

First consider the reversible adiabatic (isentropic) nozzle so from Eq.6.19

$s_{5s} - s_4 = 0 = s^o_{T5s} - s^o_{T4} - R \ln(P_5/P_4)$

$s^o_{T5s} = 8.3746 + 0.287 \ln(100/530) = 7.8960$ kJ/kg K

Table A.7.1: $T_{5s} = 808.1$ K, $\quad h_{5s} = 831.0$ kJ/kg

$\Rightarrow \quad 0.5\mathbf{V}^2_{5s} = h_4 - h_{5s} = 1312.9 - 831.0 = 481.9$ kJ/kg

Now consider the actual nozzle

Eq.7.30: $0.5\mathbf{V}^2_{5a} = \eta(0.5\mathbf{V}^2_{5s}) = 457.81$ kJ/kg $\quad \Rightarrow \quad \mathbf{V}_{5a} = \mathbf{957\ m/s}$

$h_{5a} = h_4 - 0.5\mathbf{V}^2_{5a} = 1312.9 - 457.81 = 855.1$ kJ/kg

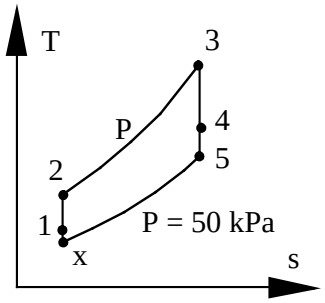
$\Rightarrow \quad T_{5a} \approx \mathbf{830\ K}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.53

A jet aircraft is flying at an altitude of 4900 m, where the ambient pressure is approximately 50 kPa and the ambient temperature is –20°C. The velocity of the aircraft is 280 m/s, the pressure ratio across the compressor is 14:1 and the cycle maximum temperature is 1450 K. Assume the inlet flow goes through a diffuser to zero relative velocity at state 1. Find the temperature and pressure at state 1.

Solution:



Ambient

$T_X = -20^oC = 253.15$ K, $P_X = 50$ kPa $= P_5$

also $\mathbf{V}_X = 280$ m/s

Assume that the air at this state is reversibly decelerated to zero velocity and then enters the compressor at 1.

$$P_2/P_1 = 14 \quad \& \quad T_3 = 1450 \text{ K}$$

C.V. Diffuser section, state 1 is the stagnation state.

Energy Eq.: $$T_1 = T_X + \frac{V_X^2}{2 \times 1000 \times C_p} = 253.15 + \frac{(280)^2}{2 \times 1000 \times 1.004} = \mathbf{292.2\ K}$$

Eq.6.23: $$P_1 = P_X \left(\frac{T_1}{T_X}\right)^{\frac{k}{k-1}} = 50 \text{ kPa} \left(\frac{292.2}{253.15}\right)^{3.5} = \mathbf{82.6\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.54

The turbine in a jet engine receives air at 1250 K, 1.5 MPa. It exhausts to a nozzle at 250 kPa, which in turn exhausts to the atmosphere at 100 kPa. The isentropic efficiency of the turbine is 85% and the nozzle efficiency is 95%. Find the nozzle inlet temperature and the nozzle exit velocity. Assume negligible kinetic energy out of the turbine.

C.V. Turbine: First the ideal (reversible and adiabatic i.e. constant s, Eq.6.23)

$$T_{es} = T_i\,(P_e/P_i) = 1250\ \text{K} \times (250/1500)^{(k-1)/k} = 749.2\ \text{K}$$

Energy Eq.: $w_{T,s} = h_i - h_{es} = C_p\,(T_i - T_{es}) = 1.004\,(1250 - 749.2) = 502.8\ \text{kJ/kg}$

Eq.7.27: $w_{T,AC} = w_{T,s} \times \eta_T = 427.4\ \text{kJ/kg} = h_i - h_{e,AC} = C_p\,(T_i - T_{e,AC})$

$$\Rightarrow\ T_{e,AC} = 1250 - 427.4 / 1.004 = \mathbf{824.3\ K},$$

C.V. Nozzle: First the ideal (reversible and adiabatic i.e. constant s, Eq.6.23)

$$\Rightarrow\ T_{es} = T_i\,(P_e/P_i)^{(k-1)/k} = 824.3\ \text{K} \times (100/250)^{(k-1)/k} = 634.4\ \text{K}$$

Energy Eq.: $(1/2)\mathbf{V}_{e,s}^2 = h_i - h_{e,s} = 1.004(824.3 - 634.4) = 190.66\ \text{kJ/kg}$

Eq.7.30: $(1/2)\mathbf{V}_{e,AC}^2 = (1/2)\mathbf{V}_{e,s}^2 \times \eta_{NOZ} = 181.13\ \text{kJ/kg}$

$$\mathbf{V}_{e,AC} = \sqrt{2 \times 1000\ \text{J/kJ} \times 181.13\ \text{kJ/kg}} = \mathbf{602\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.55

Solve the previous problem using the air tables.

Solution using air tables A.7:

C.V. Turbine: $h_i = 1336.7$, $s^o_{Ti} = 8.3940$, $s_{es} = s_i$ then from Eq.6.19

$$\Rightarrow s^o_{Tes} = s^o_{Ti} + R \ln(P_e/P_i) = 8.3940 + 0.287 \ln (250/1500) = 7.8798 \text{ kJ/kg K}$$

Table A.7.1 $T_{es} = 796$ K, $h_{es} = 817.9$ kJ/kg,

Energy Eq.: $w_{T,s} = h_i - h_{es} = 1336.7 - 817.9 = 518.8$ kJ/kg

Eq.7.27: $w_{T,AC} = w_{T,s} \times \eta_T = 441 \text{ kJ/kg} = h_i - h_{e,AC}$

$$\Rightarrow h_{e,AC} = 895.7 \Rightarrow \mathbf{T_{e,AC} = 866\ K}, \quad s^o_{Te} = 7.9730 \text{ kJ/kg K}$$

C.V. Nozzle: $h_i = 895.7$ kJ/kg, $s^o_{Ti} = 7.9730$ kJ/kgK, $s_{es} = s_i$ then from Eq.6.19

$$\Rightarrow s^o_{Tes} = s^o_{Ti} + R \ln(P_e/P_i) = 7.9730 + 0.287 \ln (100/250) = 7.7100 \text{ kJ/kgK}$$

Table A.7.1 $\Rightarrow$ $T_{e,s} = 681$ K, $h_{e,s} = 693.1$ kJ/kg

Energy Eq.: $(1/2)\mathbf{V}^2_{e,s} = h_i - h_{e,s} = 895.7 - 693.1 = 202.6$ kJ/kg

Eq.7.30: $(1/2)\mathbf{V}^2_{e,AC} = (1/2)\mathbf{V}^2_{e,s} \times \eta_{NOZ} = 192.47$ kJ/kg

$$\mathbf{V}_{e,AC} = \sqrt{2 \times 1000 \text{ J/kJ} \times 192.47 \text{ kJ/kg}} = \mathbf{620\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

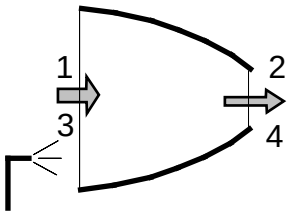
10.56

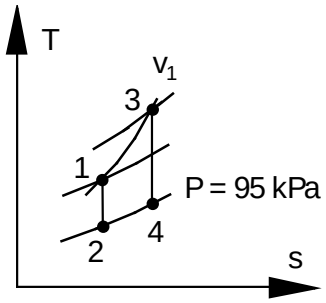
An afterburner in a jet engine adds fuel after the turbine thus raising the pressure and temperature due to the energy of combustion. Assume a standard condition of 800 K, 250 kPa after the turbine into the nozzle that exhausts at 95 kPa. Assume the afterburner adds 450 kJ/kg to that state with a rise in pressure for same specific volume, and neglect any upstream effects on the turbine. Find the nozzle exit velocity before and after the afterburner is turned on.

Solution:

Before afterburner is on: 1: 800 K; 250 kPa and 2: 95 kPa

After afterburner is on: 3: $v = v_1$ and 4: 95 kPa





Assume reversible adiabatic nozzle flow, then constant s from Eq.6.23

$$T_2 = T_1 (P_2/P_1)^{(k-1)/k} = 800 \text{ K} \times (95/250)^{0.2857} = 606.8 \text{ K}$$

Energy Eq.: $(1/2)\mathbf{V}_2^2 = C_P(T_1 - T_2)$

$$\mathbf{V}_2 = \sqrt{2\, C_P(T_1 - T_2)} = \sqrt{2 \times 1004 \text{ J/kg-K } (800 - 606.8) \text{ K}} = \mathbf{622.8 \text{ m/s}}$$

Add the q_{AB} at assumed constant volume then energy equation gives

$$T_3 = T_1 + q_{AB}/C_v = 800 \text{ K} + 450 \text{ kJ/kg}/0.717 \text{ kJ/kg-K} = 1427.6 \text{ K}$$

$$v_3 = v_1 \Rightarrow P_3 = P_1(T_3/T_1) = 250 \text{ kPa} \times 1427.6/800 = 446.1 \text{ kPa}$$

Reversible adiabatic expansion, again from Eq.6.23

$$T_4 = T_3 (P_4/P_3)^{(k-1)/k} = 1427.6 \text{ K} \times (95/446.1)^{0.2857} = 917.7 \text{ K}$$

$$\mathbf{V}_2 = \sqrt{2\, C_P(T_3 - T_4)} = \sqrt{2 \times 1004 \text{ J/kg-K } (1427.6 - 917.7) \text{ K}} = \mathbf{1012 \text{ m/s}}$$

Comment: The real process adds some fuel that burns releasing energy so the temperature goes up and due to the confined space then pressure goes up. As the pressure goes up the exit velocity increases altering the mass flow rate through the nozzle. As in most problems the real device is more complicated than we can describe with our simple analysis.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Air-standard refrigeration cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.57

An air standard refrigeration cycle has air into the compressor at 100 kPa, 270 K with a compression ratio of 3:1. The temperature after heat rejection is 300 K. Find the COP and the highest cycle temperature.

From the isentropic compression/expansion processes

$$T_2 / T_1 = (P_2/P_1)^{\frac{k-1}{k}} = 3^{0.2857} = 1.36874 = T_3/T_4$$

$$T_2 = T_1 \times 1.36874 = 270 \text{ K} \times 1.36874 = \mathbf{369.6\ K}$$

The COP, Eq.10.5, is

$$\beta = \frac{1}{\frac{T_2}{T_1} - 1} = [\ 1.36874 - 1]^{-1} = \mathbf{2.712}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.58

A standard air refrigeration cycle has -10°C, 100 kPa into the compressor, and the ambient cools the air down to 35°C at 400 kPa. Find the lowest temperature in the cycle, the low T specific heat transfer and the specific compressor work.

Solution:

State 3: 35°C = 308.2 K, 400 kPa
The lowest T is at state 4 which we can relate to state 3, constant s Eq.6.23

$$T_4 = T_3(P_4/P_3)^{\frac{k-1}{k}} = 308.2\ \text{K} \times \left(\frac{100}{400}\right)^{0.2857} = 204.9\ \text{K} = \mathbf{-68.3^oC}$$

Now the heat rejected is

$$_4q_1 = h_1 - h_4 = C_p\,(T_1 - T_4) = 1.004\ \text{kJ/kg-K} \times (-10 + 68.3)\ \text{K}$$
$$= \mathbf{58.5\ kJ/kg}$$

The isentropic compression

$$T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 263.2\ \text{K} \times \left(\frac{400}{100}\right)^{0.2857} = 391.3\ \text{K}$$

from which we get the compressor work

$$w_c = h_1 - h_2 = C_p\,(T_1 - T_2) = 1.004\ \text{kJ/kg-K} \times (263.2 - 391.3)\ \text{K}$$
$$= \mathbf{-128.6\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.59

The formula for the COP assuming cold air properties is given for the standard refrigeration cycle in Eq.10.5. Develop the similar formula for the cycle variation with a heat exchanger as shown in Fig. 10.12.

Definition of COP: $$\beta = \frac{q_L}{w_{net}} = \frac{q_L}{q_H - q_L} = \frac{1}{\frac{q_H}{q_L} - 1}$$

Assuming an ideal heat exchanger $h_4 = h_6$ and $h_1 = h_3$ so $q_L = w_E$

From the refrigeration cycle we get the ratio of the heat transfers as

$$\frac{q_H}{q_L} = \frac{C_p(T_2 - T_3)}{C_p(T_6 - T_5)} = \frac{T_2 - T_1}{T_4 - T_5} = \frac{T_1}{T_5} \frac{(T_2/T_1) - 1}{(T_4/T_5) - 1}$$

The pressure ratios are the same and we have isentropic compression/expansion

$$\frac{P_2}{P_1} = \frac{P_4}{P_5} = \left(\frac{T_2}{T_1}\right)^{k/(k-1)} = \left(\frac{T_4}{T_5}\right)^{k/(k-1)}$$

so now we get

$$\frac{T_2}{T_1} = \frac{T_4}{T_5} \qquad \text{so} \quad \frac{q_H}{q_L} = \frac{T_1}{T_5} = \frac{T_1}{T_4}\frac{T_4}{T_5} = \frac{T_1}{T_4} r_P^{(k-1)/k}$$

and the COP reduces to

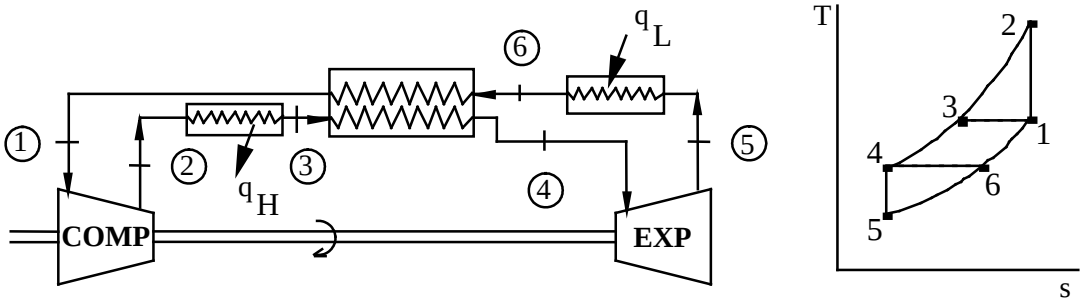
$$\beta = \frac{1}{\frac{T_1}{T_5} - 1} = \frac{1}{\frac{T_1}{T_4} r_P^{(k-1)/k} - 1}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.60

Assume a refrigeration cycle as shown in Fig. 10.12 with reversible adiabatic compressor and expander. For this cycle the low pressure is 100 kPa and the high pressure is 1.4 MPa with constant pressure heat exchangers, see Fig. 10.12 T-s diagram. The temperatures are $T_4 = T_6 = -50^oC$ and $T_1 = T_3 = 15^oC$. Find the COP for this refrigeration cycle.

Solution:



Standard air refrigeration cycle with $P_1 = 100$ kPa, $P_2 = 1.4$ MPa

We will solve the problem with cold air properties.

Compressor, isentropic $s_2 = s_1$ so from Eq.6.23

$$\Rightarrow T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 288.2 \text{ K} \times (1400/100)^{0.286} = 613 \text{ K}$$

$$w_C = -w_{12} = C_{P0}(T_2 - T_1) = 1.004 \text{ kJ/kg-K } (613 - 288.2) \text{ K} = 326 \text{ kJ/kg}$$

Expansion in expander (turbine)

$$s_5 = s_4 \Rightarrow T_5 = T_4(P_5/P_4)^{\frac{k-1}{k}} = 223.2 \text{ K} \times (100/1400)^{0.286} = 104.9 \text{ K}$$

$$w_E = C_{P0}(T_4 - T_5) = 1.004 \text{ kJ/kg-K } (223.2 - 104.9) \text{ K} = 118.7 \text{ kJ/kg}$$

Net cycle work

$$w_{NET} = w_E - w_C = 118.7 - 326.0 = -207.3 \text{ kJ/kg}$$

$$q_L = C_{P0}(T_6 - T_5) = w_E = 118.7 \text{ kJ/kg}$$

Overall cycle performance, COP

$$\beta = q_L/w_{NET} = 118.7 / 207.3 = \mathbf{0.573}$$

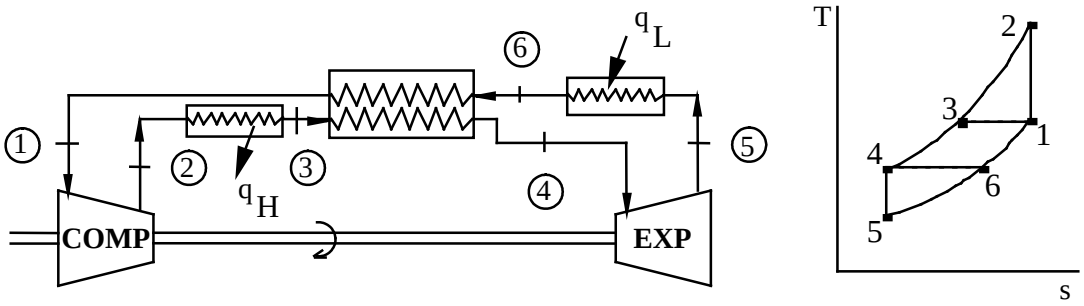
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.61

Repeat Problems 10.60, but assume that helium is the cycle working fluid instead of air. Discuss the significance of the results.

A heat exchanger is incorporated into an ideal air-standard refrigeration cycle, as shown in Fig. P10.60. It may be assumed that both the compression and the expansion are reversible adiabatic processes in this ideal case. Determine the coefficient of performance for the cycle.

Solution:



Standard air refrigeration cycle with helium and states as

$$T_1 = T_3 = 15\ ^oC = 288.2\ K, \quad P_1 = 100\ kPa, \quad P_2 = 1.4\ MPa$$

$$T_4 = T_6 = -50\ ^oC = 223.2\ K$$

Compressor, isentropic $s_2 = s_1$ so from Eq.6.23

$$\Rightarrow\ T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 288.2\left(\frac{1400}{100}\right)^{0.40} = 828.2\ K$$

$$w_C = C_{P0}(T_2 - T_1) = 5.193\ kJ/kg\text{-}K\ (828.2 - 288.2)\ K = 2804.1\ kJ/kg$$

Expansion in expander (turbine)

$$s_5 = s_4 \quad \Rightarrow \quad T_5 = T_4(P_5/P_4)^{\frac{k-1}{k}} = 223.2\ K\left(\frac{100}{1400}\right)^{0.40} = 77.7\ K$$

$$w_E = C_{P0}(T_4 - T_5) = 15.193\ kJ/kg\text{-}K\ (223.2 - 77.7)\ K = 755.5\ kJ/kg$$

Net cycle work

$$w_{NET} = 755.5 - 2804.1 = -2048.6\ kJ/kg$$

$$q_L = C_{P0}(T_6 - T_5) = 5.193\ kJ/kg\text{-}K\ (223.2 - 77.7)\ K = 755.5\ kJ/kg$$

Overall cycle performance, COP

$$\beta = q_L/w_{NET} = 755.5/2048.6 = \mathbf{0.369}$$

Notice that the low temperature is lower and work terms higher than with air. It is due to the higher heat capacity C_{P0} and ratio of specific heats (k = 1 2/3). The expense is a lower COP requiring more work input per kJ cooling.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.62

Repeat Problem 10.60, but assume an isentropic efficiency of 75% for both the compressor and the expander.

Standard air refrigeration cycle with

$T_1 = T_3 = 15\ ^oC = 288.2\ K, \quad P_1 = 100\ kPa, \quad P_2 = 1.4\ MPa$

$T_4 = T_6 = -50\ ^oC = 223.2\ K$

We will solve the problem with cold air properties.

Ideal compressor, isentropic $s_{2S} = s_1$ so from Eq.6.23

$$\Rightarrow T_{2S} = T_1(P_2/P_1)^{\frac{k-1}{k}} = 288.2(1400/100)^{0.286} = 613\ K$$

$$w_{SC} = -w_{12} = C_{P0}(T_{2S} - T_1) = 1.004(613 - 288.2) = 326\ kJ/kg$$

The actual compressor

$$w_C = w_{SC} / \eta_{SC} = 326/0.75 = 434.6\ kJ/kg$$

Expansion in ideal expander (turbine)

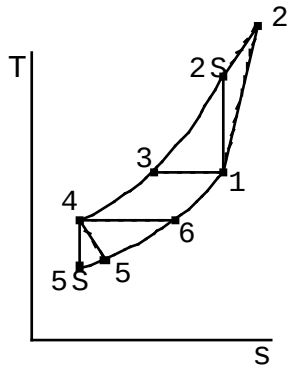
$$s_5 = s_4 \Rightarrow T_{5S} = T_4(P_5/P_4)^{\frac{k-1}{k}} = 223.2(100/1400)^{0.286} = 104.9\ K$$

$$w_E = C_{P0}(T_4 - T_5) = 1.004(223.2 - 104.9) = 118.7\ kJ/kg$$

The actual expander (turbine)

$$w_E = \eta_{SE} \times w_{SE} = 0.75 \times 118.7 = 89.0\ kJ/kg$$
$$= C_{P0}(T_4 - T_5) = 1.004(223.2 - T_5)$$

$$\Rightarrow T_5 = 134.5\ K$$



$$w_{NET} = 89.0 - 434.6 = -345.6\ kJ/kg$$

$$q_L = C_{P0}(T_6 - T_5) = 1.004(223.2 - 134.5) = 89.0\ kJ/kg$$

$$\beta = q_L/(-w_{NET}) = 89.0/345.6 = \mathbf{0.258}$$

10.63

The mean effective pressure scales with the net work and thus efficiency. Assume the heat transfer per unit mass is a given (it depends on the fuel-air mixture) how does the total power output then vary with the inlet conditions (P_1, T_1)?

The power output comes from speed and displacement in Eq. 10.11

$$\dot{W} = P_{meff} V_{displ} \frac{RPM}{60} \frac{1}{2} = m\, w_{net} \frac{RPM}{60} \frac{1}{2} = m\, \eta\, q_H \frac{RPM}{60} \frac{1}{2}$$

From the last expression we notice that the power scales with mass and efficiency. From our simple analysis we know that the efficiency only depends on compression ratio CR and not on state 1, which then leaves the mass as affected by state 1. The mass of fresh charge is assumed proportional to the mass of air at ambient conditions (close to state 1) in the volume V_{displ}. The constant of proportionality is called the volumetric efficiency and depends on the throttling and other restrictions in the intake system which then leads to state 1.

$$m \approx V_{displ} / v_1 = V_{displ}\, P_1/RT_1$$

A cold charge (T_1 low) with high pressure P_1 (a super- or turbo-charger) will give the highest mass and thus the most power.

10.64

A 4 stroke gasoline engine runs at 1800 RPM with a total displacement of 3L and a compression ratio of 10:1. The intake is at 290 K, 75 kPa with a mean effective pressure of 600 kPa. Find the cycle efficiency and power output.

Efficiency from the compression ratio

$$\eta = 1 - CR^{1-k} = 1 - 10^{-0.4} = \mathbf{0.60}$$

The power output comes from speed and displacement in Eq. 10.11

$$\dot{W} = P_{meff} V_{displ} \frac{RPM}{60} \frac{1}{2} = 600 \text{ kPa} \times 0.003 \text{ m}^3 \times \frac{1800}{60} (1/\text{s}) \times \frac{1}{2}$$

$$= \mathbf{27\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.65

Find the missing pressures and temperatures in the previous cycle.

Efficiency from the compression ratio

$$\eta = 1 - CR^{1-k} = 1 - 10^{-0.4} = 0.60$$

$$v_1 = RT_1/P_1 = 0.287 \text{ kJ/kg-K} \times 290 \text{ K}/75 \text{ kPa} = 1.10973 \text{ m}^3/\text{kg}$$

Compression: $T_2 = T_1 (CR)^{k-1} = 290 \text{ K} \times (10)^{0.4} =$ **728.45 K**

$$P_2 = P_1 (CR)^{k} = 75 \text{ kPa} \times (10)^{1.4} = \textbf{1883.9 kPa}$$

$$q_H = u_3 - u_2 = C_v(T_3 - T_2) = w_{net}/\eta = P_{meff}\,(v_1 - v_2)/\eta$$

$$= 600 \times 1.10973(1 - 1/CR)/0.60 = 998.76 \text{ kJ/kg}$$

$T_3 = T_2 + q_H/C_v = 728.45 + 998.76/0.717 =$ **2121.4 K**

$P_3 = P_2 \times (T_3/T_2) = 1883.9\ (2121.4 / 728.45) =$ **5486 kPa**

$T_4 = T_3/CR^{0.4} = 2121.4 \text{ K}/10^{0.4} =$ **844.5 K**

$P_4 = P_3/CR^{1.4} = 5486 \text{ kPa}/10^{1.4} =$ **218.4 kPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.66

Air flows into a gasoline engine at 95 kPa, 300 K. The air is then compressed with a volumetric compression ratio of 10:1. In the combustion process 1300 kJ/kg of energy is released as the fuel burns. Find the temperature and pressure after combustion using cold air properties.

Solution:

Solve the problem with constant specific heat.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

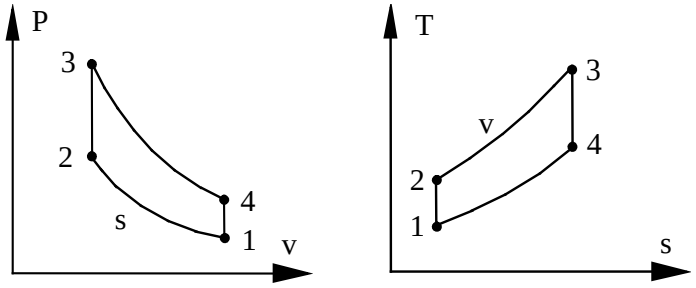
$T_2 = T_1 (v_1/v_2)^{k-1} = 300 \times 10^{0.4} = 753.6$ K

$P_2 = P_1 \times (v_1/v_2)^k = 95 \times 10^{1.4} = 2386$ kPa

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$T_3 = T_2 + q_H/C_v = 753.6 + 1300/0.717 =$ **2567 K**

$P_3 = P_2 \times (T_3/T_2) = 2386\ (2567 / 753.6) =$ **8127 kPa**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.67

A 4 stroke gasoline 4.2 L engine running at 2000 RPM has inlet state of 85 kPa, 280 K and after combustion it is 2000 K and the highest pressure is 5 MPa. Find the compression ratio, the cycle efficiency and the exhaust temperature.

Solution:

Combustion $v_3 = v_2$. Highest T and P are after combustion.

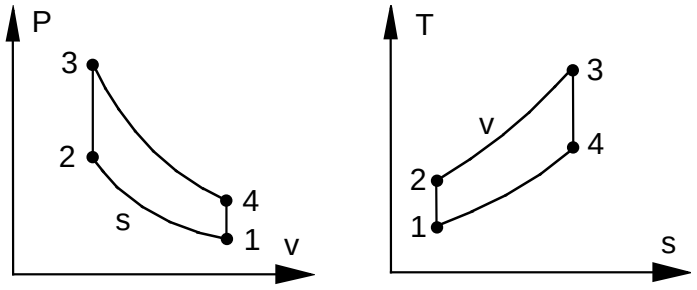
$$CR = v_1/v_2 = v_1/v_3 = (T_1P_3/T_3P_1) = \frac{280 \times 5000}{2000 \times 85} = \mathbf{8.235}$$

Efficiency from the compression ratio

$$\eta = 1 - CR^{1-k} = 1 - 8.235^{-0.4} = \mathbf{0.57}$$

Expansion

$$T_4 = T_3 (v_3/v_4)^{k-1} = T_3 [\ 1/\ CR\ ]^{k-1} = 2000 \times (1/\ 8.235)^{\ 0.4} = \mathbf{860.5\ K}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.68

Find the power from the engine in Problem 10.67

Solution:

Combustion $v_3 = v_2$. Highest T and P are after combustion.

$$CR = v_1/v_2 = v_1/v_3 = (T_1P_3/T_3P_1) = \frac{280 \times 5000}{2000 \times 85} = 8.235$$

Efficiency from the compression ratio

$$\eta = 1 - CR^{1-k} = 1 - 8.235^{-0.4} = 0.57$$

Compression: $T_2 = T_1(CR)^{k-1} = 280\ K \times (8.235)^{0.4} = 650.8\ K$

$$q_H = u_3 - u_2 = C_v(T_3 - T_2) = 0.717\ kJ/kg\text{-}K\ (2000 - 650.8)\ K = 967.4\ kJ/kg$$

$$v_1 = RT_1/P_1 = 0.287\ kJ/kg\text{-}K \times 280\ K/85\ kPa = 0.9454\ m^3/kg$$

Displacement and then mep from net work

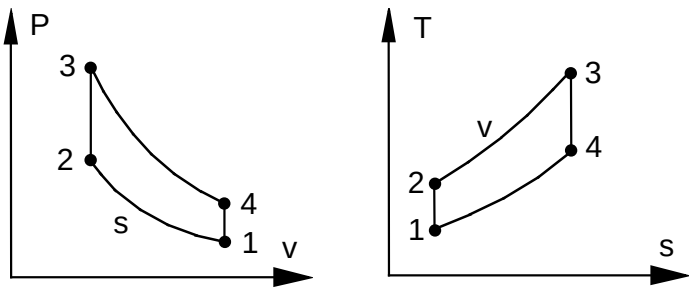
$$v_1 - v_2 = v_1 - v_1/CR = v_1[1 - (1/CR)] = 0.8306\ m^3/kg$$

$$P_{meff} = w_{net}/(v_1 - v_2) = \eta\ q_H/(v_1 - v_2)$$

$$= 0.57 \times 967.4/0.8306 = 663.9\ kPa$$

Total power from Eq. 10.11 and 4 stroke cycle

$$\dot{W} = P_{meff} V_{displ} \frac{RPM}{60} \frac{1}{2} = 663.9 \times 0.0042 \times \frac{2000}{60} \times \frac{1}{2} = \mathbf{46.45\ kW}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.69

A 4 stroke 2.4 L gasoline engine runs at 2500 RPM has an efficiency of 60%. The state before compression is 40 kPa, 280 K and after combustion it is at 2400 K. Find the highest T and P in the cycle, the specific heat transfer added, the cycle mep and the total power produced.

This is a basic 4-stroke Otto cycle.
Compression ratio from the efficiency

$$\eta = 1 - CR^{1-k} \quad => \quad CR = (1-\eta)^{-1/0.4} = 9.882$$

Compression: $T_2 = T_1(CR)^{k-1} = 280 \times (9.882)^{0.4} = 700$ K

$$P_2 = P_1\, CR^k = 40 \times 9.882^{1.4} = 988.2 \text{ kPa}$$

Combustion $v_3 = v_2$. Highest T and P are after combustion.

$$T_3 = \mathbf{2400\ K}, \quad P_3 = P_2\, T_3 / T_2 = \frac{988.2 \times 2400}{700} = \mathbf{3388\ kPa}$$

$$q_H = u_3 - u_2 = C_v(T_3 - T_2) = 0.717\ (2400 - 700) = \mathbf{1218.9\ kJ/kg}$$

$$w_{net} = \eta_{TH} \times q_H = 0.6 \times 1218.9 = 731.34 \text{ kJ/kg}$$

Displacement and P_{meff}

$$v_1 = RT_1/P_1 = (0.287 \text{ kJ/kg-K} \times 280 \text{ K})/40 \text{ kPa} = 2.009 \text{ m}^3\text{/kg}$$

$$v_2 = (1/9.882)\, v_1 = 0.2033 \text{ m}^3\text{/kg}$$

$$P_{meff} = \frac{w_{NET}}{v_1 - v_2} = \frac{731.34}{2.009 - 0.2033} = \mathbf{405\ kPa}$$

Now we can find the power from Eq.10.11

$$\dot{W} = P_{meff}\, V_{displ} \frac{RPM}{60} \frac{1}{2} = 405 \times 0.0024 \times \frac{2500}{60} \times \frac{1}{2} = \mathbf{20.3\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.70

Suppose we reconsider the previous problem and instead of the standard ideal cycle we assume the expansion is a polytropic process with n = 1.5. What are the exhaust temperature and the expansion specific work?

This is a modified 4-stroke Otto cycle. Assume the same state 1-2-3 so only state 4 is changed and thus also the efficiency is less than the original 60%. Compression ratio from the original efficiency assuming the standard cycle

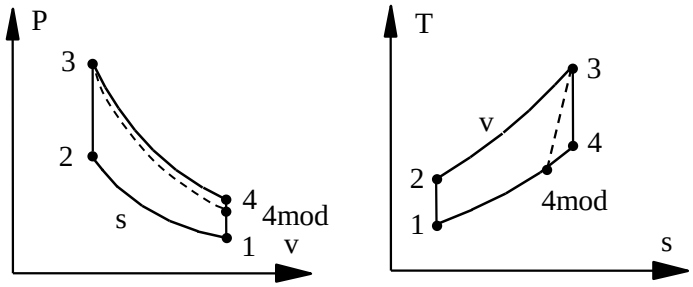
$$\eta = 1 - CR^{1-k} \quad => \quad CR = (1-\eta)^{-1/0.4} = 9.882$$

If a polytropic expansion with n = 1.5 instead then

$$T_{4mod} = T_3\, CR^{1-n} = 2400 \times 9.882^{-0.5} = \mathbf{763.5\ K}$$

This means a heat loss out and thus less work (see diagrams)

$$w = \frac{R}{1-n}(T_{4mod} - T_3) = \frac{0.287}{1-1.5}(763.5 - 2400) = \mathbf{939.35\ kJ/kg}$$



Comments:

The heat loss is

$${}_3q_4 = u_4 - u_3 + {}_3w_4 = C_v(T_4 - T_3) + {}_3w_4$$

$$= 0.717(763.5 - 2400) + 939.35 = -234\ \text{kJ/kg}$$

The original cycle has expansion work as

$$T_4 = T_3\, CR^{1-k} = 2400 \times 9.882^{-0.4} = 960\ \text{K}$$

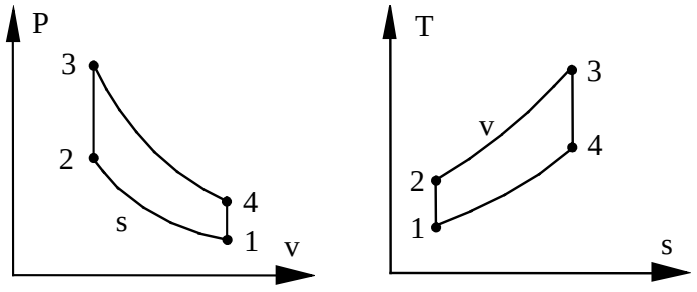
$${}_3w_4 = C_v(T_3 - T_4) = 0.717\,(2400 - 960) = 1032.5\ \text{kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.71

Air flows into a gasoline engine at 95 kPa, 300 K. The air is then compressed with a volumetric compression ratio of 8:1. In the combustion process 1300 kJ/kg of energy is released as the fuel burns. Find the temperature and pressure after combustion using cold air properties.

Solution:



Compression. Isentropic so we use Eqs.6.24-6.25

$$P_2 = P_1(v_1/v_2)^k = 95 \text{ kPa } (8)^{1.4} = 1746 \text{ kPa}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 300 \text{ K } (8)^{0.4} = 689.2 \text{ K}$$

Combustion 2 to 3:

$$T_3 = T_2 + q_H/C_v = 689.2 + 1300/0.717 = 2502.3 \text{ kJ/kg}$$

$$T_3 = \mathbf{2502\ K}$$

$$P_3 = P_2 \times (T_3/T_2) = 1746 \times \frac{2502}{689.2} = \mathbf{6338\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.72

A gasoline engine has a volumetric compression ratio of 8 and before compression has air at 280 K, 85 kPa. The combustion generates a peak pressure of 5500 kPa. Find the peak temperature, the energy added by the combustion process and the exhaust temperature.

Solution:

Solve the problem with cold air properties.

Compression. Isentropic so we use Eqs.6.24-6.25

$$P_2 = P_1(v_1/v_2)^k = 85 \text{ kPa } (8)^{1.4} = 1562 \text{ kPa}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 280 \text{ K } (8)^{0.4} = 643.3 \text{ K}$$

Combustion. Constant volume

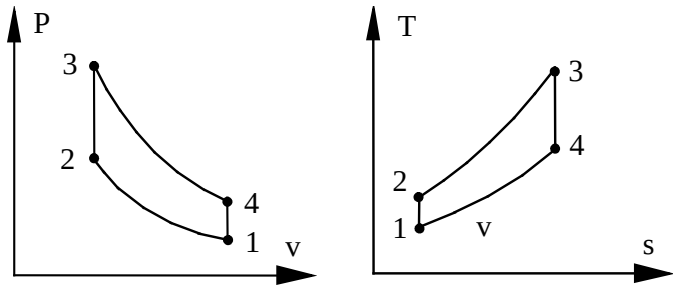
$$T_3 = T_2 \, (P_3/P_2) = 643.3 \text{ K} \times 5500/1562 = \mathbf{2265\ K}$$

$$q_H = u_3 - u_2 \approx C_v(T_3 - T_2)$$

$$= 0.717 \text{ kJ/kg-K } (2265 - 643.3) \text{ K} = \mathbf{1163\ kJ/kg}$$

Exhaust. Isentropic expansion so from Eq.6.24

$$T_4 = T_3/8^{0.4} = 2265 \text{ K } /2.2974 = \mathbf{986\ K}$$

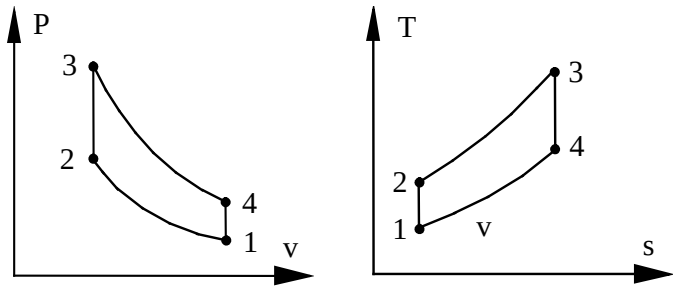


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.73

To approximate an actual spark-ignition engine consider an air-standard Otto cycle that has a heat addition of 1800 kJ/kg of air, a compression ratio of 7, and a pressure and temperature at the beginning of the compression process of 90 kPa, 10°C. Assuming constant specific heat, with the value from Table A.5, determine the maximum pressure and temperature of the cycle, the thermal efficiency of the cycle and the mean effective pressure.

Solution:



Compression: Reversible and adiabatic so constant s from Eq.6.24-25

$$P_2 = P_1(v_1/v_2)^k = 90 \text{ kPa } (7)^{1.4} = 1372 \text{ kPa}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 283.2 \text{ K} \times (7)^{0.4} = 616.6 \text{ K}$$

Combustion: constant volume

$$T_3 = T_2 + q_H/C_{V0} = 616.6 + 1800/0.717 = \mathbf{3127\ K}$$

$$P_3 = P_2T_3/T_2 = 1372 \text{ kPa} \times 3127 / 616.6 = \mathbf{6958\ kPa}$$

Efficiency and net work

$$\eta_{TH} = 1 - T_1/T_2 = 1 - 283.2/616.5 = \mathbf{0.541}$$

$$w_{net} = \eta_{TH} \times q_H = 0.541 \times 1800 = 973.8 \text{ kJ/kg}$$

Displacement and P_{meff}

$$v_1 = RT_1/P_1 = (0.287 \text{ kJ/kg-K} \times 283.2 \text{ K})/90 \text{ kPa} = 0.9029 \text{ m}^3/\text{kg}$$

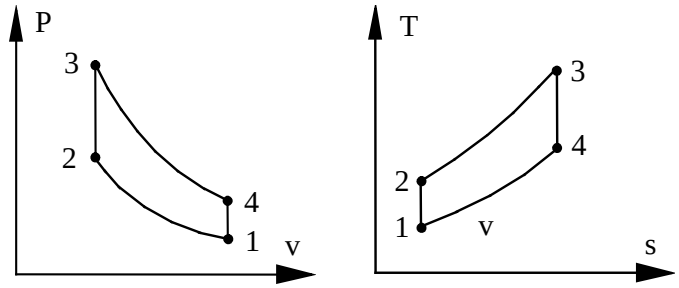
$$v_2 = (1/7)\, v_1 = 0.1290 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{NET}}{v_1 - v_2} = \frac{973.8}{0.9029 - 0.129} = \mathbf{1258\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.74

A 3.3 L minivan engine runs at 2000 RPM with a compression ratio of 10:1. The intake is at 50 kPa, 280 K and after expansion it is at 750 K. Find the highest T in the cycle, the specific heat transfer added by combustion and the mean effective pressure.



Compression: Reversible and adiabatic so constant s from Eq.6.24-25

$$T_2 = T_1(v_1/v_2)^{k-1} = 280 \times (10)^{0.4} = 703.3 \text{ K}$$

Expansion: isentropic, T_3 is the highest T and T_4 was given

$$T_3 = T_4\, CR^{k-1} = 750 \text{ K} \times 10^{0.4} = \mathbf{1883.9\ K}$$

$$q_H = u_3 - u_2 = C_{V0}\,(T_3 - T_2) = 0.717\ (1883.9 - 703.3) = \mathbf{846.5\ kJ/kg}$$

Efficiency and net work

$$\eta_{TH} = 1 - T_1/T_2 = 1 - 280/703.3 = 0.602$$

$$w_{net} = \eta_{TH} \times q_H = 0.602 \times 846.5 = 509.6 \text{ kJ/kg}$$

Displacement and P_{meff}

$$v_1 = RT_1/P_1 = (0.287 \text{ kJ/kg-K} \times 280 \text{ K})/50 \text{ kPa} = 1.6072 \text{ m}^3/\text{kg}$$

$$v_2 = (1/10)\, v_1 = 0.16072 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{NET}}{v_1 - v_2} = \frac{509.6}{1.6072 - 0.16072} = \mathbf{352.3\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.75

A gasoline engine takes air in at 290 K, 90 kPa and then compresses it. The combustion adds 1000 kJ/kg to the air after which the temperature is 2050 K. Use cold air properties (i.e. constant heat capacities at 300 K) and find the compression ratio, the compression specific work and the highest pressure in the cycle.

Solution:

Standard Otto Cycle

Combustion process: $T_3 = 2050$ K; $u_2 = u_3 - q_H$

$$T_2 = T_3 - q_H / C_{vo} = 2050 - 1000 / 0.717 = 655.3 \text{ K}$$

Compression process

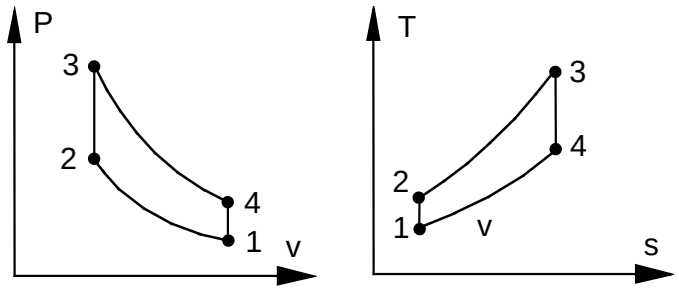
$$P_2 = P_1(T_2 / T_1)^{k/(k-1)} = 90(655.3/290)^{3.5} = 1561 \text{ kPa}$$

$$CR = v_1 / v_2 = (T_2 / T_1)^{1/(k-1)} = (655.3 / 290)^{2.5} = \mathbf{7.67}$$

$$-{}_1w_2 = u_2 - u_1 = C_{vo}(T_2 - T_1) = 0.717 \text{ kJ/kg-K } (655.3 - 290) \text{ K} = \mathbf{262 \text{ kJ/kg}}$$

Highest pressure is after the combustion where $v_3 = v_2$ so we get

$$P_3 = P_2T_3 / T_2 = 1561 \text{ kPa} \times 2050 / 655.3 = \mathbf{4883 \text{ kPa}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.76

Answer the same three questions for the previous problem, but use variable heat capacities (use table A.7).

A gasoline engine takes air in at 290 K, 90 kPa and then compresses it. The combustion adds 1000 kJ/kg to the air after which the temperature is 2050 K. Use the cold air properties (i.e. constant heat capacities at 300 K) and find the compression ratio, the compression specific work and the highest pressure in the cycle.

Solution:

Standard Otto cycle, solve using Table A.7.1

Combustion process: $T_3 = 2050$ K ; $u_3 = 1725.7$ kJ/kg

$$u_2 = u_3 - q_H = 1725.7 - 1000 = 725.7 \text{ kJ/kg}$$

$$\Rightarrow T_2 = 960.5 \text{ K} ; \qquad s^o_{T2} = 8.0889 \text{ kJ/kg K}$$

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.19

$$0 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1) = s^o_{T2} - s^o_{T1} - R \ln(T_2 v_1/T_1 v_2)$$

$$= 8.0889 - 6.8352 - 0.287 \ln(960.5/290) - 0.287 \ln(v_1/v_2)$$

Solving => $v_1 / v_2 =$ **23.78**

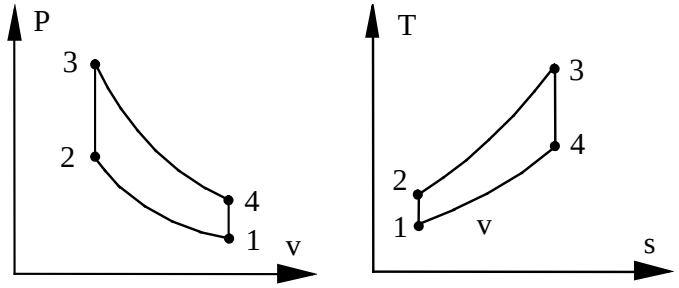
Comment: This is much too high for an actual Otto cycle.

$$-{}_1w_2 = u_2 - u_1 = 725.7 - 207.2 = \mathbf{518.5\ kJ/kg}$$

Highest pressure is after combustion where $v_3 = v_2$ so we get

$$P_3 = P_2 T_3 / T_2 = P_1 (T_3 / T_1)(v_1 / v_3)$$

$$= 90 \times (2050 / 290) \times 23.78 = \mathbf{15\ 129\ kPa}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.77

Redo the previous problem but assume the combustion adds 1225 kJ/kg.

Standard Otto cycle, solve using Table A.7.1

Combustion process: $T_3 = 2050$ K ; $u_3 = 1725.7$ kJ/kg

$u_2 = u_3 - q_H = 1725.7 - 1225 = 500.7$ kJ/kg

$\Rightarrow T_2 = 684.8$ K ; $\quad s^o_{T2} = 7.71647$ kJ/kg K

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.19

$$0 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1) = s^o_{T2} - s^o_{T1} - R \ln(T_2 v_1/T_1 v_2)$$

$$= 7.71647 - 6.83521 - 0.287 \ln(684.8/290) - 0.287 \ln(v_1/v_2)$$

Solving => $v_1 / v_2 =$ **9.13**

$-{}_1w_2 = u_2 - u_1 = 500.7 - 207.2 =$ **293.5 kJ/kg**

Highest pressure is after combustion where $v_3 = v_2$ so we get

$$P_3 = P_2 T_3 / T_2 = P_1 (T_3 / T_1)(v_1 / v_3)$$

$$= 90 \times (2050 / 290) \times 9.13 = \textbf{5 809 kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.78

A four stroke gasoline engine has a compression ratio of 10:1 with 4 cylinders of total displacement 2.3 L. the inlet state is 280 K, 70 kPa and the engine is running at 2100 RPM with the fuel adding 1400 kJ/kg in the combustion process. What is the net work in the cycle and how much power is produced?

Solution:

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2 = 10$

$$\eta_{TH} = 1 - r_v^{1-k} = 1 - 10^{-0.4} = 0.602$$

$$w_{net} = \eta_{TH} \times q_H = 0.602 \times 1400 = \mathbf{842.8\ kJ/kg}$$

We also need specific volume to evaluate Eqs.10.9 to 10.11

$$v_1 = RT_1 / P_1 = 0.287 \times 280 / 70 = 1.148\ m^3/kg$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = \frac{w_{net}}{v_1 \left(1 - \frac{1}{r_v}\right)} = \frac{842.8}{1.148 \times 0.9} = 815.7\ kPa$$

Now we can find the power from Eq.10.11

$$\dot{W} = P_{meff}\, V_{displ} \frac{RPM}{60} \frac{1}{2} = 815.7 \times 0.0023 \times \frac{2100}{60} \times \frac{1}{2} = \mathbf{32.8\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.79

A gasoline engine has a volumetric compression ratio of 10 and before compression has air at 290 K, 85 kPa in the cylinder. The combustion peak pressure is 6000 kPa. Assume cold air properties. What is the highest temperature in the cycle? Find the temperature at the beginning of the exhaust (heat rejection) and the overall cycle efficiency.

Solution:

Compression. Isentropic so we use Eqs.6.24-25

$$P_2 = P_1(v_1/v_2)^k = 85 \text{ kPa } (10)^{1.4} = 2135.1 \text{ kPa}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 290 \text{ K } (10)^{0.4} = 728.45 \text{ K}$$

Combustion. Constant volume

$$T_3 = T_2 (P_3/P_2) = 728.45 \text{ K} \times 6000/2135.1 = \mathbf{2047\ K}$$

Exhaust is after the isentropic expansion so from Eq.6.24

$$T_4 = T_3 / (v_1/v_2)^{k-1} = T_3 / 10^{0.4} = 2047 / 2.5119 = \mathbf{814.9\ K}$$

Overall cycle efficiency is from Eq.10.12 $r_v = v_1/v_2$

$$\eta = 1 - r_v^{1-k} = 1 - 10^{-0.4} = \mathbf{0.602}$$

Comment: No actual gasoline engine has an efficiency that high, maybe 35%.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.80

Repeat Problem 10.73, but assume variable specific heat. The ideal gas air tables, Table A.7, are recommended for this calculation (or the specific heat from Fig. 3.26 at high temperature).

Solution:

Table A.7: $T_1 = 283.2$ K, $u_1 = 202.3$ kJ/kg, $s^o_{T1} = 6.8113$ kJ/kg K

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.19

$$0 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1) = s^o_{T2} - s^o_{T1} - R \ln(T_2 v_1/T_1 v_2)$$

$$s^o_{T2} - R \ln(T_2/T_1) = s^o_{T1} + R \ln(v_1/v_2) = 6.8113 + 0.287 \ln 7 = 7.3698$$

This becomes trial and error so estimate first at 600 K and use A.7.1.

$LHS_{600} = 7.5764 - 0.287 \ln(600/283.2) = 7.3609$ (too low)

$LHS_{620} = 7.6109 - 0.287 \ln(620/283.2) = 7.3860$ (too high)

Interpolate to get: $T_2 = 607.1$ K, $u_2 = 440.5$ kJ/kg

$\Rightarrow {}_1w_2 = u_2 - u_1 = 238.2$ kJ/kg,

$u_3 = 440.5 + 1800 = 2240.5 \Rightarrow T_3 =$ **2575.8 K**, $s^o_{T3} = 9.2859$ kJ/kgK

$P_3 = P_1 (v_1/v_3) T_3/T_1 = 90 \text{ kPa} \times 7 \times 2575.8 / 283.2 =$ **5730 kPa**

Expansion 3 to 4: $s_4 = s_3 \Rightarrow$ From Eq.6.19 as before

$$s^o_{T4} - R \ln(T_4/T_3) = s^o_{T3} + R \ln(v_3/v_4) = 9.2859 + 0.287 \ln(1/7) = 8.7274$$

This becomes trial and error so estimate first at 1400 K and use A.7.1.

$LHS_{1400} = 8.5289 - 0.287 \ln(1400/2575.8) = 8.7039$ (too low)

$LHS_{1450} = 8.5711 - 0.287 \ln(1450/2575.8) = 8.7360$ (too high)

Interpolation $\Rightarrow T_4 = 1436.6$ K, $u_4 = 1146.9$ kJ/kg

${}_3w_4 = u_3 - u_4 = 2240.5 - 1146.9 = 1093.6$ kJ/kg

Net work, efficiency and mep

$$w_{net} = {}_3w_4 + {}_1w_2 = 1093.6 - 238.2 = 855.4 \text{ kJ/kg}$$

$$\eta_{TH} = w_{net} / q_H = 855.4 / 1800 = \mathbf{0.475}$$

$$v_1 = \frac{RT_1}{P_1} = \frac{0.287 \times 283.2}{90} = 0.9029 \text{ m}^3/\text{kg}; \quad v_2 = \frac{v_1}{CR} = 0.1290 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = 855.4 / (0.9029 - 0.129) = \mathbf{1105 \text{ kPa}}$$

Comment: Iterations are avoided by the use of the v_r function in A.7.2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.81

Assume a state of 5000 kPa, 2100 K after combustion in an Otto cycle with a compression ratio of 10:1; the intake temperature is 300 K. Find the missing temperatures in the cycle using Table A.7 and then give the average value of *k* (ratio of specific heats) for the compression and expansion processes.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.19

$$0 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1) = s^o_{T2} - s^o_{T1} - R \ln(T_2 v_1/T_1 v_2)$$

$$s^o_{T2} - R \ln(T_2/T_1) = s^o_{T1} + R \ln(v_1/v_2) = 6.86926 + 0.287 \ln 10 = 7.5301$$

This becomes trial and error so estimate first at 600 K and use A.7.1.

$LHS_{700} = 7.7401 - 0.287 \ln(700/300) = 7.49692$ (too low)

$LHS_{740} = 7.80008 - 0.287 \ln(740/300) = 7.54096$ (too high)

Interpolate to get: $T_2 =$ **730.1 K**, $u_2 = 536.5$ kJ/kg

Expansion 3 to 4: $s_4 = s_3 \Rightarrow$ From Eq.6.19 as before

$$s^o_{T4} - R \ln(T_4/T_3) = s^o_{T3} + R \ln(v_3/v_4) = 9.02721 - 0.287 \ln 10 = 8.36637$$

This becomes trial and error so estimate first at 1400 K and use A.7.1.

$LHS_{1100} = 8.24449 - 0.287 \ln(1100/2100) = 8.43007$ (too high)

$LHS_{1050} = 8.19081 - 0.287 \ln(1050/2100) = 8.389743$ (still too high)

$LHS_{1000} = 8.13493 - 0.287 \ln(1000/2100) = 8.347866$ (too low)

Interpolation $\Rightarrow$ $T_4 =$ **1022.1 K**, $u_4 = 778.15$ kJ/kg

Compression process

$$C_v = \frac{u_2 - u_1}{T_2 - T_2} = \frac{536.5 - 214.36}{730.1 - 300} = 0.749; \quad k = (C_v + R)/C_v = \mathbf{1.38}$$

Expansion process

$$C_v = \frac{u_3 - u_4}{T_3 - T_4} = \frac{1774.06 - 778.15}{2100 - 1022.1} = 0.9239; \quad k = (C_v + R)/C_v = \mathbf{1.31}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.82

An Otto cycle has the lowest T as 290 K and the lowest P is 150 kPa, the highest T is 2400 K and combustion adds 1200 kJ/kg as heat transfer. Find the compression ratio and the mean effective pressure.

Solution:

Identify states: $T_1 = 290$ K, $P_1 = 150$ kPa, $T_3 = 2400$ K, $q_H = 1200$ kJ/kg

Combustion: $q_H = u_3 - u_2 = C_{vo}(T_3 - T_2) = 1200$ kJ/kg

$$T_2 = T_3 - q_H / C_{vo} = 2400 - 1200/0.717 = 726.36 \text{ K}$$

Compression: $CR = r_v = v_1/v_2 = (T_2/T_1)^{1/(k-1)} = \left(\frac{726.36}{290}\right)^{2.5} =$ **9.93**

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2 = 9.93$

$$\eta_{TH} = 1 - r_v^{1-k} = 1 - T_1/T_2 = 1 - 290/726.36 = 0.601$$

$$w_{net} = \eta_{TH} \times q_H = 0.601 \times 1200 = 721.2 \text{ kJ/kg}$$

We also need specific volume to evaluate Eqs.10.9 to 10.11

$$v_1 = RT_1 / P_1 = 0.287 \times 290 / 150 = 0.55487 \text{ m}^3/\text{kg}$$

$$v_2 = v_1/CR = 0.05588 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = \frac{721.2}{0.55487 - 0.05588} \frac{\text{kJ/kg}}{\text{m}^3/\text{kg}} = \textbf{1445 kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.83

The cycle in the previous problem is used in a 2.4 L engine running 1800 RPM. How much power does it produce?

Identify states: $T_1 = 290$ K, $P_1 = 85$ kPa, $T_3 = 2400$ K, $q_H = 1200$ kJ/kg

Combustion: $q_H = u_3 - u_2 = C_{vo}(T_3 - T_2) = 1200$ kJ/kg

$$T_2 = T_3 - q_H / C_{vo} = 2400 - 1200/0.717 = 726.36 \text{ K}$$

Compression: $CR = r_v = v_1/v_2 = (T_2/T_1)^{1/(k-1)} = \left(\frac{726.36}{290}\right)^{2.5} = 9.93$

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2 = 9.93$

$$\eta_{TH} = 1 - r_v^{1-k} = 1 - T_1/T_2 = 1 - 290/726.36 = 0.601$$

$$w_{net} = \eta_{TH} \times q_H = 0.601 \times 1200 = 721.2 \text{ kJ/kg}$$

We also need specific volume to evaluate Eqs.10.9 to 10.11

$$v_1 = RT_1 / P_1 = 0.287 \times 290 / 150 = 0.55487 \text{ m}^3/\text{kg}$$

$$v_2 = v_1/CR = 0.05588 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = \frac{721.2}{0.55487 - 0.05588} \frac{\text{kJ/kg}}{\text{m}^3/\text{kg}} = 1445 \text{ kPa}$$

Now we can find the power from Eq.10.11

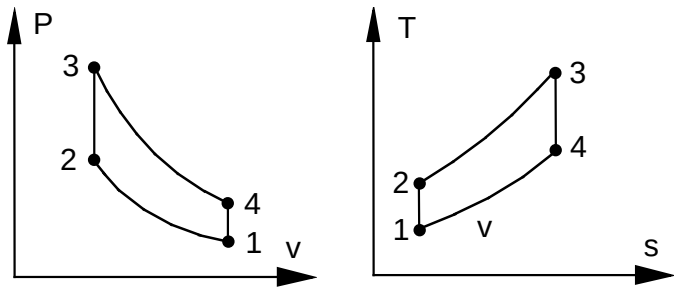
$$\dot{W} = P_{meff} V_{displ} \frac{\text{RPM}}{60} \frac{1}{2} = 1445 \times 0.0024 \times \frac{1800}{60} \times \frac{1}{2} = \mathbf{52\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.84

When methanol produced from coal is considered as an alternative fuel to gasoline for automotive engines, it is recognized that the engine can be designed with a higher compression ratio, say 10 instead of 7, but that the energy release with combustion for a stoichiometric mixture with air is slightly smaller, about 1700 kJ/kg. Repeat Problem 10.73 using these values.

Solution:



Compression: Reversible and adiabatic so constant s from Eq.6.24-25

$P_2 = P_1(v_1/v_2)^k = 90\ \text{kPa}\ (10)^{1.4} = 2260.7\ \text{kPa}$

$T_2 = T_1(v_1/v_2)^{k-1} = 283.15\ \text{K}\ (10)^{0.4} = 711.2\ \text{K}$

Combustion: constant volume

$T_3 = T_2 + q_H / C_{vo} = 711.2 + 1700 / 0.717 =$ **3082 K**

$P_3 = P_2(T_3 / T_2) = 2260.7\ \text{kPa} \times 3082 / 711.2 =$ **9797 kPa**

Efficiency, net work, displacement and P_{meff}

$\eta_{TH} = 1 - T_1/T_2 = 1 - 283.15/711.2 =$ **0.602**

$w_{net} = \eta_{TH} \times q_H = 0.6 \times 1700 = 1023.4\ \text{kJ/kg}$

$v_1 = RT_1/P_1 = 0.287\ \text{kJ/kg-K} \times 283.15\ \text{K}/90\ \text{kPa} = 0.9029\ \text{m}^3/\text{kg},$

$v_2 = v_1/10 = 0.0903\ \text{m}^3/\text{kg}$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = 1023.4 / (0.9029 - 0.0903) =$$ **1255 kPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.85

It is found experimentally that the power stroke expansion in an internal combustion engine can be approximated with a polytropic process with a value of the polytropic exponent *n* somewhat larger than the specific heat ratio *k*. Repeat Problem 10.73 but assume that the expansion process is reversible and polytropic (instead of the isentropic expansion in the Otto cycle) with *n* equal to 1.50. From the average temperature during expansion estimate the actual average *k*.

See solution to 10.73 except for process 3 to 4.

T_3 = **3127 K**, P_3 = **6.958 MPa**

$v_3 = RT_3/P_3 = v_2 = 0.129$ m^3/kg, $v_4 = v_1 = 0.9029$ m^3/kg

Process: $Pv^{1.5}$ = constant.

$P_4 = P_3(v_3/v_4)^{1.5} = 6958\ (1/7)^{1.5} = 375.7$ kPa

$T_4 = T_3(v_3/v_4)^{0.5} = 3127(1/7)^{0.5} = 1181.9$ K

$$_1w_2 = \int Pdv = \frac{R}{1-1.4}(T_2 - T_1) = \frac{0.287}{-0.4}(606.6 - 283.15) = -239.3 \text{ kJ/kg}$$

$$_3w_4 = \int Pdv = R(T_4 - T_3)/(1 - 1.5)$$

$$= -0.287(1181.9 - 3127)/0.5 = 1116.5 \text{ kJ/kg}$$

$w_{NET} = 1116.5 - 239.3 = 877.2$ kJ/kg

$\eta_{CYCLE} = w_{NET}/q_H = 877.2/1800 =$ **0.487**

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = 877.2/(0.9029 - 0.129) = \textbf{1133 kPa}$$

Note a smaller w_{NET}, η_{CYCLE}, P_{meff} compared to an ideal cycle.

The T changes from 3 to 4 (3127 K to 1181.9 K) average is about 2150 K.

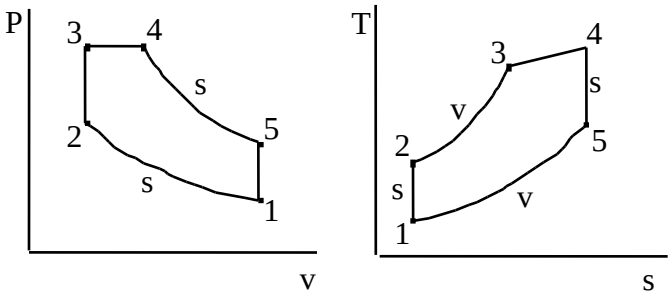
$$C_{P0} = \frac{h_{2200} - h_{2100}}{2200 - 2100} = \frac{2502.63 - 2376.82}{2200 - 2100} = 1.258 \text{ kJ/kg-K}$$

$k = C_{P0}/(C_{P0} - R) = 1.258/(1.258 - 0.287) =$ **1.296**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.86

In the Otto cycle all the heat transfer q_H occurs at constant volume. It is more realistic to assume that part of q_H occurs after the piston has started its downward motion in the expansion stroke. Therefore, consider a cycle identical to the Otto cycle, except that the first two-thirds of the total q_H occurs at constant volume and the last one-third occurs at constant pressure. Assume that the total q_H is 2100 kJ/kg, that the state at the beginning of the compression process is 90 kPa, 20°C, and that the compression ratio is 9. Calculate the maximum pressure and temperature and the thermal efficiency of this cycle. Compare the results with those of a conventional Otto cycle having the same given variables.



$P_1 = 90$ kPa, $T_1 = 20^oC$

$r_V = v_1/v_2 = 9$

$q_{23} = (2/3) \times 2100$

$= 1400$ kJ/kg;

$q_{34} = 2100/3 = 700$ kJ/kg

Constant s compression, Eqs.6.24-25

$$P_2 = P_1(v_1/v_2)^k = 90 \text{ kPa } (9)^{1.4} = 1951 \text{ kPa}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 293.15 \text{ K } (9)^{0.4} = 706 \text{ K}$$

Constant v combustion

$$T_3 = T_2 + q_{23}/C_{V0} = 706 + 1400/0.717 = \mathbf{2660\ K}$$

$$P_3 = P_2T_3/T_2 = 1951 \text{ kPa } (2660/706) = \mathbf{7350.8\ kPa} = P_4$$

Constant P combustion

$$T_4 = T_3 + q_{34}/C_{P0} = 2660 + 700/1.004 = 3357 \text{ K}$$

Remaining expansion:

$$\frac{v_5}{v_4} = \frac{v_1}{v_4} = \frac{P_4}{P_1} \times \frac{T_1}{T_4} = \frac{7350.8}{90} \times \frac{293.15}{3357} = 7.131$$

$$T_5 = T_4(v_4/v_5)^{k-1} = 3357 \text{ K } (1/7.131)^{0.4} = 1530 \text{ K}$$

$$q_L = C_{V0}(T_5 - T_1) = 0.717 \text{ kJ/kg-K } (1530 - 293.15) \text{ K} = 886.2 \text{ kJ/kg}$$

$$\eta_{TH} = 1 - q_L/q_H = 1 - 886.2/2100 = \mathbf{0.578}$$

Std. Otto Cycle: $\eta_{TH} = 1 - (9)^{-0.4} = \mathbf{0.585}$, small difference

10.87

A gasoline engine has a volumetric compression ratio of 9. The state before compression is 290 K, 90 kPa, and the peak cycle temperature is 1800 K. Find the pressure after expansion, the cycle net work and the cycle efficiency using properties from Table A.7.2.

Compression 1 to 2: $s_2 = s_1 \Rightarrow v_{r2} = v_{r1}(v_2/v_1)$

$v_{r2} = 196.37/9 = 21.819 \Rightarrow T_2 \cong 680$ K, $P_{r2} \cong 20.784$, $u_2 = 496.94$

$P_2 = P_1(P_{r2}/P_{r1}) = 90$ kPa (20.784 / 0.995) = 1880 kPa

${}_1w_2 = u_1 - u_2 = 207.19 - 496.94 = -289.75$ kJ/kg

Combustion 2 to 3:

$q_H = u_3 - u_2 = 1486.33 - 496.94 = 989.39$ kJ/kg

$P_3 = P_2(T_3/T_2) = 1880$ kPa (1800 / 680) = 4976 kPa

Expansion 3 to 4:

$s_4 = s_3 \Rightarrow v_{r4} = v_{r3} \times 9 = 1.143 \times 9 = 10.278$

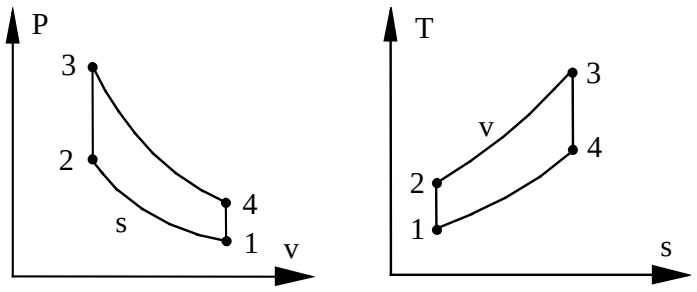
$\Rightarrow T_4 = 889$ K, $P_{r4} = 57.773$, $u_4 = 665.8$ kJ/kg

$P_4 = P_3(P_{r4}/P_{r3}) = 4976$ kPa (57.773 / 1051) = **273.5 kPa**

${}_3w_4 = u_3 - u_4 = 1486.33 - 665.8 = 820.5$ kJ/kg

$w_{NET} = {}_3w_4 + {}_1w_2 = 820.5 - 289.75 =$ **530.8 kJ/kg**

$\eta = w_{NET}/q_H = 530.8/989.39 =$ **0.536**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.88

Solve Problem 10.76 using the P_r and v_r functions from Table A7.2

A gasoline engine takes air in at 290 K, 90 kPa and then compresses it. The combustion adds 1000 kJ/kg to the air after which the temperature is 2050 K. Use the cold air properties (i.e. constant heat capacities at 300 K) and find the compression ratio, the compression specific work and the highest pressure in the cycle.

Solution:

Standard Otto cycle, solve using Table A.7.1 and Table A.7.2

Combustion process: $T_3 = 2050$ K ; $u_3 = 1725.7$ kJ/kg

$$u_2 = u_3 - q_H = 1725.7 - 1000 = 725.7 \text{ kJ/kg}$$

$$\Rightarrow T_2 = 960.5 \text{ K} ; \qquad v_{r2} = 8.2166$$

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From the v_r function

$$v_1/v_2 = v_{r1}/v_{r2} = \frac{195.36}{8.2166} = \mathbf{23.78}$$

Comment: This is much too high for an actual Otto cycle.

$$-{}_1w_2 = u_2 - u_1 = 725.7 - 207.2 = \mathbf{518.5\ kJ/kg}$$

Highest pressure is after combustion

$$P_3 = P_2T_3 / T_2 = P_1(T_3 / T_1)(v_1 / v_3)$$

$$= 90 \text{ kPa} \times (2050 / 290) \times 23.78 = \mathbf{15\ 129\ kPa}$$

10.89

A diesel engine has an inlet at 95 kPa, 300 K and a compression ratio of 20:1. The combustion releases 1300 kJ/kg. Find the temperature after combustion using cold air properties.

Solution:

Compression process (isentropic) from Eqs.6.24-25

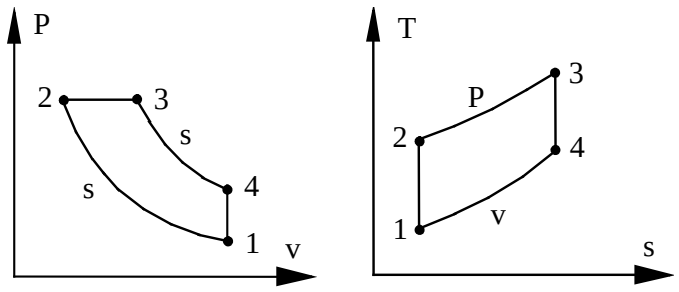
$$T_2 = T_1(v_1 / v_2)^{k-1} = 300 \times 20^{0.4} = 994.3 \text{ K}$$

Combustion at constant P which is the maximum pressure

$${}_2w_3 = P\,(v_3 - v_2)$$

$${}_2q_3 = u_3 - u_2 + {}_2w_3 = h_3 - h_2 = C_{po}(T_3 - T_2)$$

$$T_3 = T_2 + {}_2q_3 / C_{po} = 994.3 + 1300 /1.004 = \mathbf{2289\ K}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.90

A diesel engine has a state before compression of 95 kPa, 290 K, and a peak pressure of 6000 kPa, a maximum temperature of 2400 K. Find the volumetric compression ratio and the thermal efficiency.

Solution:

Standard Diesel cycle and we will use cold air properties.

Compression process (isentropic) from Eqs.6.24-25:

$$(P_2/P_1) = (v_1/v_2)^k = CR^{1.4}$$

$$CR = v_1/v_2 = (P_2/P_1)^{1/k} = (6000/95)^{1/1.4} = \mathbf{19.32}$$

$$T_2 = T_1(P_2/P_1)^{k-1/k} = 290 \times (6000/95)^{0.2857} = 947.9 \text{ K}$$

Combustion and expansion volumes

$$v_3 = v_2 \times T_3/T_2 = v_1\, T_3/(T_2 \times CR)\ ; \quad v_4 = v_1$$

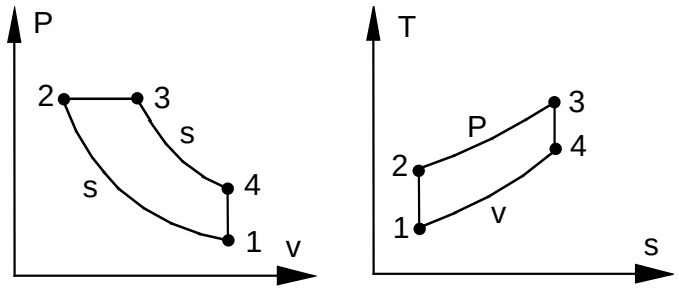
Expansion process, isentropic from Eq.6.23

$$T_4 = T_3\,(v_3/v_4)^{k-1} = T_3\,[T_3/\,(CR \times T_2)]^{k-1}$$

$$= 2400 \text{ K} \times [\ 2400/(19.32 \times 947.9)\ ]^{0.4} = 1064.6 \text{ K}$$

Efficiency from Eq.10.13

$$\eta = 1 - \frac{1}{k}\frac{T_4 - T_1}{T_3 - T_2} = 1 - \frac{1}{1.4}\frac{1064.6 - 290}{2400 - 947.9} = \mathbf{0.619}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.91

Find the cycle efficiency and mean effective pressure for the cycle in Problem 10.89

Solution:

Compression process (isentropic) from Eqs.6.24-25

$$T_2 = T_1(v_1 / v_2)^{k-1} = 300 \times 20^{0.4} = 994.3 \text{ K}$$

Combustion at constant P which is the maximum pressure

$$_2w_3 = P\,(v_3 - v_2)$$

$$_2q_3 = u_3 - u_2 + {}_2w_3 = h_3 - h_2 = C_{po}(T_3 - T_2)$$

$$T_3 = T_2 + {}_2q_3 / C_{po} = 994.3 + 1300 /1.004 = 2289 \text{ K}$$

Combustion and expansion volumes

$$v_3 = v_2 \times T_3/T_2 = v_1\, T_3/(T_2 \times CR)\ ; \quad v_4 = v_1$$

Expansion process, isentropic from Eq.6.23

$$T_4 = T_3\,(v_3/v_4)^{k-1} = T_3\,[T_3/\,(CR \times T_2)]^{k-1}$$

$$= 2289 \times [\ 2289/(20 \times 994.3)\ ]^{0.4} = 964 \text{ K}$$

Efficiency from Eq.10.13

$$\eta = 1 - \frac{1}{k}\frac{T_4 - T_1}{T_3 - T_2} = 1 - \frac{1}{1.4}\frac{964 - 300}{2289 - 994.3} = \mathbf{0.634}$$

$$w_{net} = \eta\, q_H = 0.634 \times 1300 = 824.2 \text{ kJ/kg}$$

$$v_1 = RT_1/P_1 = 0.9063 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{net}}{v_{max} - v_{min}} = \frac{w_{net}}{v_1 - v_1/CR}$$

$$= \frac{824.2}{0.9063\,(1 - 1/20)}\ \frac{\text{kJ/kg}}{\text{m}^3/\text{kg}} = \mathbf{957\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.92

The **cut off ratio** is the ratio of v_3/v_2, see Fig. 10.18, which is the expansion while combustion occurs at constant pressure. Determine this ratio for the cycle in Problem 10.89.

Solution:

Compression process (isentropic) from Eqs.6.24-25

$$T_2 = T_1(v_1 / v_2)^{k-1} = 300 \times 20^{0.4} = 994.3 \text{ K}$$

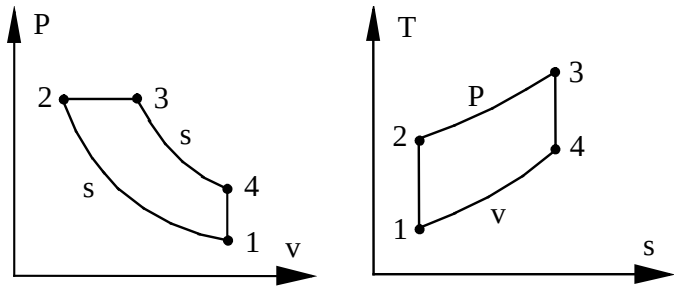
Combustion at constant $P_2 = P_3$ which is the maximum pressure

$${}_2w_3 = P\,(v_3 - v_2)$$

$${}_2q_3 = u_3 - u_2 + {}_2w_3 = h_3 - h_2 = C_{po}(T_3 - T_2)$$

$$T_3 = T_2 + {}_2q_3 / C_{po} = 994.3 + 1300 /1.004 = 2289 \text{ K}$$

Cut-off ratio: $v_3 / v_2 = T_3 /T_2 = 2289 / 994.3 =$ **2.302**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.93

A diesel engine has a compression ratio of 20:1 with an inlet of 95 kPa, 290 K, state 1, with volume 0.5 L. The maximum cycle temperature is 1800 K. Find the maximum pressure, the net specific work, the cut off ratio, see problem 10.92, and the thermal efficiency.

Solution:

Compression process (isentropic) from Eqs. 6.24-25

$$T_2 = T_1(v_1 / v_2)^{k-1} = 290 \times 20^{0.4} = 961 \text{ K}$$

$$P_2 = 95 \times (20)^{1.4} = 6297.5 \text{ kPa} ;$$

$$v_2 = v_1/20 = RT_1/(20\, P_1) = 0.043805 \text{ m}^3/\text{kg}$$

$$-{}_1w_2 = u_2 - u_1 \approx C_{vo}(T_2 - T_1) = 0.717\ (961 - 290) = 481.1 \text{ kJ/kg}$$

Combustion at constant P which is the maximum pressure

$$P_3 = P_2 = \mathbf{6298\ kPa} ;$$

$$v_3 = v_2\, T_3 /T_2 = 0.043805 \times 1800/961 = 0.08205 \text{ m}^3/\text{kg}$$

Cut-off ratio: $v_3 / v_2 = T_3 /T_2 = 1800 / 961 = \mathbf{1.873}$

$${}_2w_3 = P\,(v_3 - v_2) = 6298 \times (0.08215 - 0.043805) = 241.5 \text{ kJ/kg}$$

$${}_2q_3 = u_3 - u_2 + {}_2w_3 = h_3 - h_2 = C_{po}(T_3 - T_2)$$

$$= 1.004(1800 - 961) = 842.4 \text{ kJ/kg}$$

Expansion process (isentropic) from Eq.6.24

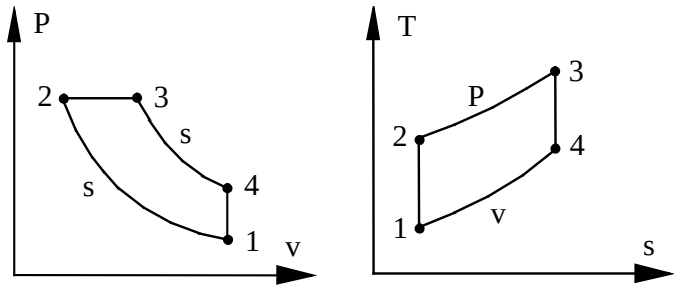
$$T_4 = T_3(v_3 / v_4)^{0.4} = 1800\ (0.08205 / 0.8761)^{0.4} = 698 \text{ K}$$

$${}_3w_4 = u_3 - u_4 \approx C_{vo}(T_3 - T_4) = 0.717\ (1800 - 698) = 790.1 \text{ kJ/kg}$$

Cycle net work and efficiency

$$w_{net} = {}_2w_3 + {}_3w_4 + {}_1w_2 = 241.5 + 790.1 - 481.1 = \mathbf{550.5\ kJ/kg}$$

$$\eta = w_{net} / q_H = 550.5/ 842.4 = \mathbf{0.653}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.94

A diesel engine has a bore of 0.1 m, a stroke of 0.11 m and a compression ratio of 19:1 running at 2000 RPM (revolutions per minute). Each cycle takes two revolutions and has a mean effective pressure of 1400 kPa. With a total of 6 cylinders find the engine power in kW and horsepower, hp.

Solution:

Work from mean effective pressure, Eq.10.9.

$$P_{meff} = \frac{w_{net}}{v_{max} - v_{min}} \quad => \quad w_{net} = P_{meff}\,(v_{max} - v_{min})$$

The displacement is

$$\Delta V = \pi Bore^2 \times 0.25 \times S = \pi \times 0.1^2 \times 0.25 \times 0.11 = 0.000864\ m^3$$

Work per cylinder per power stroke, Eq.10.10

$$W = P_{meff}(V_{max} - V_{min}) = 1400 \times 0.000864\ kPa\ m^3 = 1.2096\ kJ/cycle$$

Only every second revolution has a power stroke so we can find the power, see also Eq.10.11

$$\dot{W} = W \times N_{cyl} \times RPM \times 0.5\ (cycles / min) \times (min / 60\ s) \times (kJ / cycle)$$

$$= 1.2096 \times 6 \times 2000 \times 0.5 \times (1/60) = \mathbf{121\ kW} = \mathbf{162\ \ hp}$$

The conversion factor from kW to hp is from Table A.1 under power.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.95

A super charger is used for a two stroke 10 L diesel engine so intake is 200 kPa, 320 K and the cycle has compression ratio of 18:1 and mean effective pressure of 830 kPa. The engine is 10 L running at 200 RPM find the power output.

Solution:

The power is from Eq.10.11

$$\dot{W} = m\, w_{net} \times N_{cyl} \times RPM \times 1/60$$

$$= m\, P_{meff} (v_1 - v_2) \times N_{cyl} \times RPM/60 = P_{meff}\, V_{displ}\, RPM/60$$

$$= 830 \text{ kPa} \times 0.010 \text{ m}^3 \times 200 \text{ (rev/min)} / 60 \text{ (s/min)} = \mathbf{27.7\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.96

A diesel engine has a state before compression of 95 kPa, 290 K, and a peak pressure of 6000 kPa, a maximum temperature of 2400 K. Use the air tables to find the volumetric compression ratio and the thermal efficiency.

Solution:

Compression: $s_2 = s_1$ => from Eq.6.19

$$s^o_{T2} = s^o_{T1} + R \ln(P_2 / P_1) = 6.8352 + 0.287 \ln(6000/95) = 8.025 \text{ kJ/kg K}$$

A.7.1 => $T_2 = 907.6$ K; $h_2 = 941.16$ kJ/kg;

$$h_3 = 2755.8 \text{ kJ/kg}; \quad s^o_{T3} = 9.19586 \text{ kJ/kg K}$$

$$q_H = h_3 - h_2 = 2755.8 - 941.16 = 1814.2 \text{ kJ/kg}$$

$$CR = v_1/v_2 = (T_1/T_2)(P_2/P_1) = (290/907.6) \times (6000/95) = \mathbf{20.18}$$

Expansion process

$$s^o_{T4} = s^o_{T3} + R \ln(P_4 / P_3) = s^o_{T3} + R \ln(T_4 / T_3) + R \ln(v_3/v_4)$$

$$v_3/v_4 = v_3/v_1 = (v_2/v_1) \times (T_3/T_2) = (T_3/T_2)\,(1/CR)$$

$$= (2400/907.6)\,(1/20.18) = 0.13104$$

$$s^o_{T4} - R \ln(T_4 / T_3) = s^o_{T3} + R \ln(v_3/v_4) = 9.1958 + 0.287 \ln 0.13104 = 8.61254$$

Trial and error on T_4 since it appears both in s^o_{T4} and the ln function

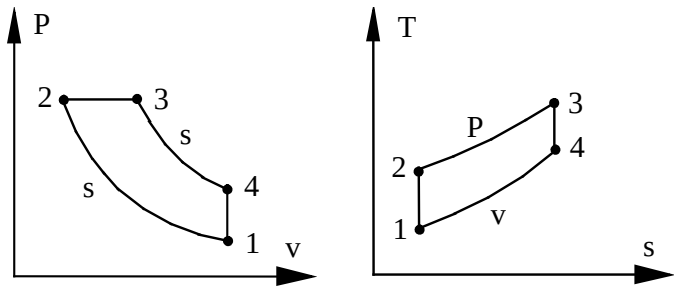
$T_4 = 1300$ K LHS = $8.4405 - 0.287 \ln (1300/2400) = 8.616$

$T_4 = 1250$ K LHS = $8.3940 - 0.287 \ln (1250/2400) = 8.5812$

Now Linear interpolation $T_4 = 1295$ K, $u_4 = 1018.26$ kJ/kg

$$q_L = u_4 - u_1 = 1018.26 - 207.19 = 811.08 \text{ kJ/kg}$$

$$\eta = 1 - (q_L/ q_H) = 1 - (811.08/1814.2) = \mathbf{0.553}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.97

At the beginning of compression in a diesel cycle T = 300 K, P = 200 kPa and after combustion (heat addition) is complete T = 1500 K and P = 7.0 MPa. Find the compression ratio, the thermal efficiency and the mean effective pressure.

Solution:

Standard Diesel cycle. See P-v and T-s diagrams for state numbers.

Compression process (isentropic) from Eqs.6.24-8.25

$P_2 = P_3 = 7000$ kPa => $v_1 / v_2 = (P_2/P_1)^{1/k} = (7000 / 200)^{0.7143} =$ **12.67**

$T_2 = T_1(P_2 / P_1)^{(k-1)/k} = 300$ K $(7000 / 200)^{0.2857} = 828.4$ K

Expansion process (isentropic) first get the volume ratios

$v_3 / v_2 = T_3 / T_2 = 1500 / 828.4 = 1.81$

$v_4 / v_3 = v_1 / v_3 = (v_1 / v_2)(v_2 / v_3) = 12.67 / 1.81 = 7$

The exhaust temperature follows from Eq.6.24

$T_4 = T_3(v_3 / v_4)^{k-1} = 1500$ K $(1 / 7)^{0.4} = 688.7$ K

$q_L = C_{vo}(T_4 - T_1) = 0.717$ kJ/kg-K (688.7 - 300) K = 278.5 kJ/kg

$q_H = h_3 - h_2 \approx C_{po}(T_3 - T_2) = 1.004$ kJ/kg-K (1500 - 828.4) K = 674 kJ/kg

Overall performance

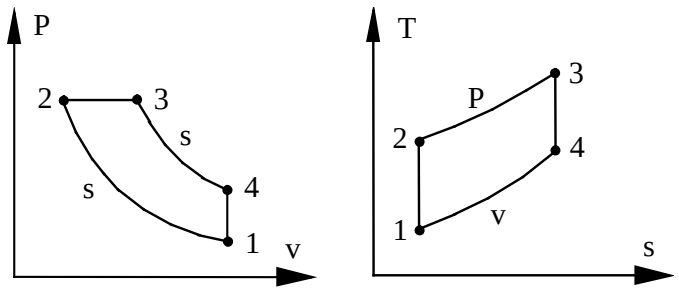
$\eta = 1 - q_L / q_H = 1 - 278.5 / 674 =$ **0.587**

$w_{net} = q_{net} = q_H - q_L = 674 - 278.5 = 395.5$ kJ/kg

$v_{max} = v_1 = R\,T_1 / P_1 = 0.287$ kJ/kg-K $\times 300$ K/ 200 kPa = 0.4305 m^3/kg

$v_{min} = v_{max} / (v_1 / v_2) = 0.4305 / 12.67 = 0.034$ m^3/kg

$$P_{meff} = \frac{w_{net}}{v_{max} - v_{min}} = 395.5 / (0.4305 - 0.034) = \textbf{997 kPa}$$



Remark: This is a too low compression ratio for a practical diesel cycle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.98

The worlds largest diesel engine has displacement of 25 m^3 running at 200 RPM in a two stroke cycle producing 100 000 hp. Assume an inlet state of 200 kPa, 300 K and a compression ratio of 20:1. What is the mean effective pressure and the flow of air to the engine?

We have 3 parameters for the cycle: T_1, P_1 and CR we need one more, so this comes from the total rate of work.

$$\dot{W} = m\, w_{net} \times N_{cyl} \times RPM \times 1/60$$
$$= m\, P_{meff} (v_1 - v_2) \times N_{cyl} \times RPM/60 = P_{meff}\, V_{displ}\, RPM/60$$

$$P_{meff} = \dot{W}\, 60 / V_{displ}\, RPM = \frac{100\,000 \times 0.746\ kW \times 60\ s}{25\ m^3 \times 200} = \mathbf{895\ kPa}$$

With this information we could now get all the cycle states etc.
Assume the displacement volume is filled with air at state 1, then

$$m = \frac{P_1 V_{displ}}{RT_1} = \frac{200\ kPa \times 25\ m^3}{0.287\ kJ/kg\text{-}K \times 300\ K} = 58.07\ kg$$

This is repeated 200 times per minute so the rate is

$$\dot{m} = m \times RPM \times 1/60 = 58.07\ 200 / 60 = \mathbf{193.57\ kg}/s$$

A similar engine is in this container ship shown at dock. The engine was build up inside the ship as it is too large to put in finished. The cranes are on the port dock.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.99

A diesel engine has air before compression at 280 K, 85 kPa. The highest temperature is 2200 K and the highest pressure is 6 MPa. Find the volumetric compression ratio and the mean effective pressure using cold air properties at 300 K.

Solution:

Compression $(P_2/P_1) = (v_1/v_2)^k = CR^k$

$$CR = v_1/v_2 = (P_2/P_1)^{1/k} = (6000/85)^{1/1.4} = \mathbf{20.92}$$

$$T_2 = T_1(P_2/P_1)^{k-1/k} = 280 \times (6000/85)^{0.2857} = 944.8 \text{ K}$$

Combustion. Highest temperature is after combustion.

$$h_2 = C_P(T_3 - T_2) = 1.004 \text{ kJ/kg-K } (2200 - 944.8) \text{ K} = 1260.2 \text{ kJ/kg}$$

Expansion ($v_4 = CR \times v_2$ and $P_2 = P_3$)

$$T_4 = T_3 (v_3/v_4)^{k-1} = T_3 [v_3 / (CR \times v_2)]^{k-1} = T_3 [T_3/ (CR \times T_2)]^{k-1}$$

$$= 2200 \text{ K} \times (2200/20.92 \times 944.8)^{0.4} = 914.2 \text{ K}$$

$$q_L = u_4 - u_1 = C_V(T_4 - T_1) = 0.717 \text{ kJ/kg-K } (914.2 - 280) \text{ K} = 454.7 \text{ kJ/kg}$$

$$v_1 = RT_1/P_1 = 0.287 \text{ kJ/kg-K} \times 280 \text{ K}/85 \text{ kPa} = 0.9454 \text{ m}^3/\text{kg}$$

Displacement and mep from net work

$$v_1 - v_2 = v_1 - v_1/CR = v_1[1 - (1/CR)] = 0.9002 \text{ m}^3/\text{kg}$$

$$P_{meff} = w_{net}/(v_1 - v_2) = (q_H - q_L)/(v_1 - v_2)$$

$$= (1260.2 - 454.7)/0.9002 = \mathbf{894.8 \text{ kPa}}$$

10.100

Consider an ideal air-standard diesel cycle in which the state before the compression process is 95 kPa, 290 K, and the compression ratio is 20. Find the thermal efficiency for a maximum temperature of 2000 K

Solution:

Diesel cycle: $P_1 = 95$ kPa, $T_1 = 290$ K, $CR = v_1/v_2 = 20$,

$$v_1 = 0.287 \text{ kJ/kg-K} \times 290 \text{ K}/95 \text{ kPa} = 0.8761 \text{ m}^3/\text{kg} = v_4 = CR\ v_2,$$

Compression process (isentropic) from Eqs.6.24-25

$$T_2 = T_1(v_1 / v_2)^{k-1} = 290 \text{ K} \times 20^{0.4} = 961.2 \text{ K}$$

Combustion at constant P which is the maximum pressure

$$v_3 = v_2\ T_3 / T_2 = \frac{0.8761}{20} \text{ m}^3/\text{kg} \times \frac{2000}{961.2} = 0.09115 \text{ m}^3/\text{kg}$$

Expansion process (isentropic) from Eq.6.24

$$T_4 = T_3(v_3 / v_4)^{0.4} = 2000 \text{ K } (0.09115 / 0.8761)^{\ 0.4} = 808.9 \text{ K}$$

Cycle net work and efficiency

$$\eta_{TH} = 1 - \frac{T_4 - T_1}{k(T_3 - T_2)} = 1 - \frac{808.9 - 290}{1.4\ (2000 - 961.2)} = \mathbf{0.643}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.101

Solve Problem 10.90 using the P_r and v_r functions from Table A7.2

A diesel engine has a state before compression of 95 kPa, 290 K, and a peak pressure of 6000 kPa, a maximum temperature of 2400 K. Find the volumetric compression ratio and the thermal efficiency.

Solution:

Compression: $s_2 = s_1$ => From definition of the P_r function

$$P_{r2} = P_{r1} (P_2/P_1) = 0.9899 (6000/95) = 62.52$$

A.7.1 => $T_2 = 907$ K; $h_2 = 941.0$ kJ/kg;

$$h_3 = 2755.8 \text{ kJ/kg}; \quad v_{r3} = 0.43338$$

$$q_H = h_3 - h_2 = 2755.8 - 941.0 = 1814.8 \text{ kJ/kg}$$

$$CR = v_1/v_2 = (T_1/T_2)(P_2/P_1) = (290/907) \times (6000/95) = \mathbf{20.19}$$

Expansion process

$$v_{r4} = v_{r3} (v_4 / v_3) = v_{r3} (v_1 / v_3) = v_{r3} (v_1 / v_2) \times (T_2/T_3)$$

$$= v_{r3} \, CR \times (T_2/T_3) = 0.43338 \times 20.19 \times (907/2400) = 3.30675$$

Linear interpolation $T_4 = 1294.8$ K, $u_4 = 1018.1$ kJ/kg

$$q_L = u_4 - u_1 = 1018.1 - 207.2 = 810.9 \text{ kJ/kg}$$

$$\eta = 1 - (q_L/q_H) = 1 - (810.9/1814.8) = \mathbf{0.553}$$

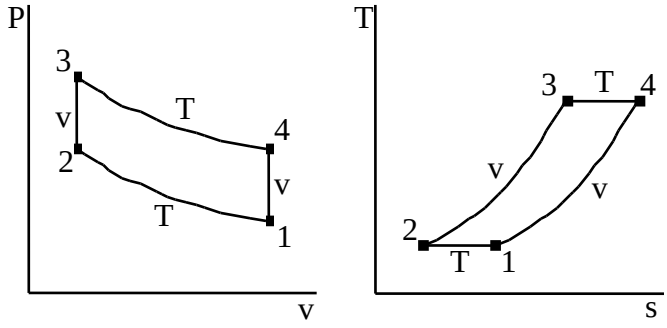
Stirling and Carnot Cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.102

Consider an ideal Stirling-cycle engine in which the state at the beginning of the isothermal compression process is 100 kPa, 25°C, the compression ratio is 6, and the maximum temperature in the cycle is 1100°C. Calculate the maximum cycle pressure and the thermal efficiency of the cycle with and without regenerators.



Ideal Stirling cycle
$T_1 = T_2 = 25\ ^oC$
$P_1 = 100$ kPa
$CR = v_1/v_2 = 6$
$T_3 = T_4 = 1100\ ^oC$

Isothermal compression (heat goes out)

$$T_1 = T_2 \ \Rightarrow\ P_2 = P_1(v_1/v_2) = 100\ \text{kPa} \times 6 = 600\ \text{kPa}$$

$$_1w_2 = {}_1q_2 = -RT_1 \ln(v_1/v_2) = -0.287 \times 298.2 \ln(6) = -153.3\ \text{kJ/kg}$$

Constant volume heat addition

$$V_2 = V_3 \ \Rightarrow\ P_3 = P_2T_3/T_2 = 600 \times 1373.2/298.2 = \mathbf{2763\ kPa}$$

$$q_{23} = u_3 - u_2 = C_{v\,o}(T_3 - T_2) = 0.717\ (1100 - 25) = 770.8\ \text{kJ/kg}$$

Isothermal expansion (heat comes in)

$$w_{34} = q_{34} = RT_3 \ln(v_4/v_3) = 0.287 \times 1373.2 \times \ln 6 = 706.1\ \text{kJ/kg}$$

$$w_{net} = 706.1 - 153.3 = 552.8\ \text{kJ/kg}$$

Efficiency without regenerator, (q_{23} and q_{34} are coming in from source)

$$\eta_{\text{NO REGEN}} = \frac{w_{net}}{q_{23} + q_{34}} = \frac{552.8}{770.8 + 706.1} = \mathbf{0.374,}$$

Efficiency with regenerator, (Now only q_{34} is coming in from source)

$$\eta_{\text{WITH REGEN}} = \frac{w_{net}}{q_{34}} = \frac{552.8}{706.1} = \mathbf{0.783}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.103

An air-standard Stirling cycle uses helium as the working fluid. The isothermal compression brings helium from 100 kPa, 37°C to 600 kPa. The expansion takes place at 1200 K and there is no regenerator. Find the work and heat transfer in all of the 4 processes per kg helium and the thermal cycle efficiency.

Helium table A.5: $R = 2.077$ kJ/kg K, $C_{vo} = 3.1156$ kJ/kg K

Compression/expansion: $v_4 / v_3 = v_1 / v_2 = P_2 / P_1 = 600 / 100 = 6$

1 -> 2 $\quad {}_1w_2 = -q_{12} = \int P\, dv = R\, T_1 \ln(v_1 / v_2) = RT_1 \ln (P_2 / P_1)$

$= 2.077$ kJ/kg-K $\times$ 310 K $\times$ ln 6 = **1153.7 kJ/kg**

2 -> 3 : $\quad {}_2w_3 = \mathbf{0}$; $\quad q_{23} = C_{vo}(T_3 - T_2) = 3.1156(1200 - 310) =$ **2773 kJ/kg**

3 -> 4: $\quad {}_3w_4 = q_{34} = R\, T_3 \ln \dfrac{v_4}{v_3} = 2.077 \times 1200 \ln 6 =$ **4465.8 kJ/kg**

4 -> 1 $\quad {}_4w_1 = \mathbf{0}$; $\quad q_{41} = C_{vo}(T_4 - T_1) =$ **-2773 kJ/kg**

$$\eta_{cycle} = \frac{{}_1w_2 + {}_3w_4}{q_{23} + q_{34}} = \frac{-1153.7 + 4465.8}{2773 + 4465.8} = \mathbf{0.458}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.104

Consider an ideal air-standard Stirling cycle with an ideal regenerator. The minimum pressure and temperature in the cycle are 100 kPa, 25°C, the compression ratio is 10, and the maximum temperature in the cycle is 1000°C. Analyze each of the four processes in this cycle for work and heat transfer, and determine the overall performance of the engine.

Ideal Stirling cycle diagram as in Fig. 10.19, with

$$P_1 = 100 \text{ kPa}, \quad T_1 = T_2 = 25^{o}\text{C}, \quad v_1/v_2 = 10, \quad T_3 = T_4 = 1000^{o}\text{C}$$

From 1-2 at const T: $_1w_2 = {}_1q_2 = T_1(s_2 - s_1)$

$$= -RT_1\ln(v_1/v_2) = -0.287 \times 298.2 \times \ln(10) = -197.1 \text{ kJ/kg}$$

From 2-3 at const V: $_2w_3 = \mathbf{0}$

$$q_{23} = C_{V0}(T_3 - T_2) = 0.717\ (1000 - 25) = \mathbf{699\ kJ/kg}$$

From 3-4 at const T; $_3w_4 = {}_3q_4 = T_3(s_4 - s_3)$

$$= +RT_3 \times \ln\frac{v_4}{v_3} = 0.287 \times 1237.2 \times \ln(10) = \mathbf{841.4\ kJ/kg}$$

From 4-1 at const V; $_4w_1 = \mathbf{0}$

$$q_{41} = C_{V0}(T_1 - T_4) = 0.717\ (25 - 1000) = \mathbf{-699\ kJ/kg}$$

$$w_{NET} = -197.1 + 0 + 841.4 + 0 = 644.3 \text{ kJ/kg}$$

Since q_{23} is supplied by $-q_{41}$ (regenerator)

$$q_H = q_{34} = 841.4 \text{ kJ/kg}, \quad \eta_{TH} = \frac{w_{NET}}{q_H} = \frac{644.3}{841.4} = \mathbf{0.766}$$

NOTE: $q_H = q_{34} = RT_3 \times \ln(10), \quad q_L = -{}_1q_2 = RT_1 \times \ln(10)$

$$\eta_{TH} = \frac{q_H - q_L}{q_H} \textbf{ Error! Bookmark not defined.} = \frac{T_3 - T_1}{T_3} = \frac{975}{1273.2} = 0.766$$

= Carnot efficiency

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.105

The air-standard Carnot cycle was not shown in the text; show the *T–s* diagram for this cycle. In an air-standard Carnot cycle the low temperature is 320 K and the efficiency is 50%. If the pressure before compression and after heat rejection is 100 kPa, find the high temperature and the pressure just before heat addition.

Solution:

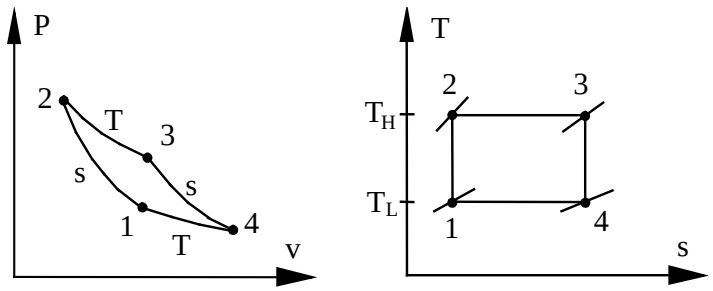
Carnot cycle efficiency from Eq.7.5

$$\eta = 0.5 = 1 - T_H/T_L$$

$$\Rightarrow \; T_H = T_L/0.5 = \mathbf{640\ K}$$

Just before heat addition is state 2 and after heat rejection is state 1 so $P_1 = 100$ kPa and the isentropic compression is from Eq.6.23

$$P_2 = P_1 (T_H / T_L)^{\frac{k}{k-1}} = \mathbf{1131\ kPa}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.106

Air in a piston/cylinder goes through a Carnot cycle in which $T_L = 26.8°C$ and the total cycle efficiency is $\eta = 2/3$. Find T_H, the specific work and volume ratio in the adiabatic expansion for constant C_P, C_v.

Solution:

Carnot cycle efficiency Eq.5.5:

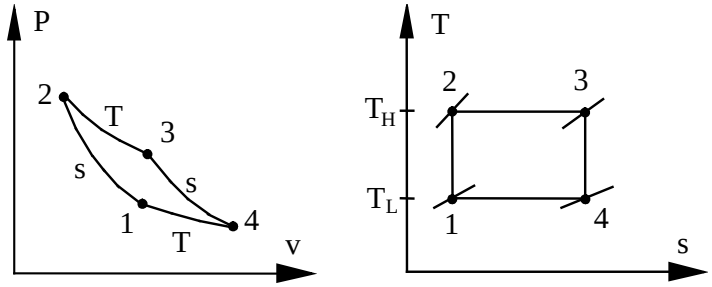
$$\eta = 1 - T_L/T_H = 2/3 \Rightarrow \quad T_H = 3 \times T_L = 3 \times 300 = \mathbf{900\ K}$$

Adiabatic expansion 3 to 4: Pv^k = constant, work from Eq.6.29 (n = k)

$$_3w_4 = (P_4v_4 - P_3v_3)/(1 - k) = \frac{R}{1 - k}(T_4 - T_3) = u_3 - u_4$$

$$= C_v(T_3 - T_4) = 0.717\ \text{kJ/kg-K}\ (900 - 300)\ \text{K} = \mathbf{429.9\ kJ/kg}$$

$$v_4/v_3 = (T_3/T_4)^{1/(k - 1)} = 3^{2.5} = \mathbf{15.6}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.107

Do the problem 10.105 using values from Table A.7.1.
The air-standard Carnot cycle was not shown in the text; show the *T–s* diagram for this cycle. In an air-standard Carnot cycle the low temperature is 320 K and the efficiency is 50%. If the pressure before compression and after heat rejection is 100 kPa, find the high temperature and the pressure just before heat addition.

Solution:

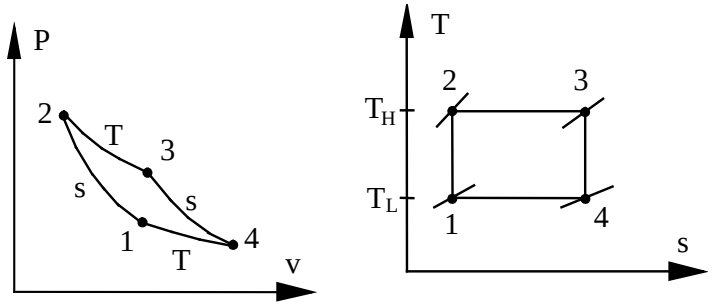
Carnot cycle efficiency Eq.7.5:

$$\eta = 1 - T_L/T_H = 1/2 \;\Rightarrow\; T_H = 2 \times T_L = 2 \times 320 = \mathbf{640\ K}$$

From A.7.1: $s^\circ_{T1} = 6.93413$ kJ/kg K, $s^\circ_{T2} = 7.64448$ kJ/kg K

From the entropy $s_1 = s_2$ and Eq. 6.19 we get

$$P_2 = P_1 \exp[\,(s^\circ_{T2} - s^\circ_{T1})/R] = 100 \text{ kPa} \exp[\,(7.64448 - 6.93413)/0.287]$$
$$= 1188 \text{ kPa}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.108

Do Problem 10.105 using the P_r, v_r functions in Table A.7.2

The air-standard Carnot cycle was not shown in the text; show the *T–s* diagram for this cycle. In an air-standard Carnot cycle the low temperature is 320 K and the efficiency is 50%. If the pressure before compression and after heat rejection is 100 kPa, find the high temperature and the pressure just before heat addition.

Solution:

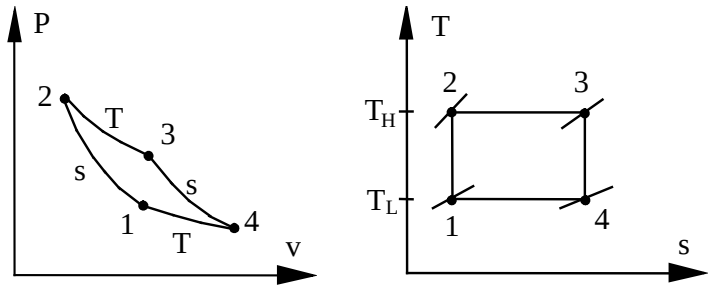
Carnot cycle efficiency Eq.7.5:

$$\eta = 1 - T_L/T_H = 1/2 \Rightarrow \quad T_H = 2 \times T_L = 2 \times 320 = 640 \text{ K}$$

From A.7.2: $P_{r1} = 1.3972$, $P_{r2} = 16.598$

From the entropy $s_1 = s_2$ and equation below Table A.7.2 we get

$$P_2 = P_1 \, P_{r2} / P_{r1} = 100 \text{ kPa} \times 16.598 / 1.3972 = \mathbf{1188 \text{ kPa}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Atkinson and Miller cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.109

An Atkinson cycle has state 1 as 150 kPa, 300 K, compression ratio of 9 and a heat release of 1000 kJ/kg. Find the needed expansion ratio.

Solution:

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 300 \text{ K} \times 9^{0.4} = 722.5 \text{ K}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 150 \text{ kPa} \times 9^{1.4} = 3251 \text{ kPa}$$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$$T_3 = T_2 + q_H/C_v = 722.5 \text{ K} + 1000 \text{ kJ/kg} / 0.717 \text{ kJ/kg-K} = 2117 \text{ K}$$

$$P_3 = P_2 \times (T_3/T_2) = 3251 \text{ kPa} (2117 / 722.5) = 9526 \text{ kPa}$$

The expansion should now bring pressure down so $P_4 = P_1$

$$P_4 = P_1 = P_3 \times (v_3/v_4)^{k} = P_3 \times CR^{-k} \Rightarrow CR = (P_3 / P_4)^{1/k}$$

$$CR = (9526 / 150)^{0.71429} = \mathbf{19.4}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.110

An Atkinson cycle has state 1 as 150 kPa, 300 K, compression ratio of 9 and expansion ratio of 14. Find the needed heat release in the combustion.

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 300 \text{ K} \times 9^{0.4} = 722.5 \text{ K}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 150 \text{ kPa} \times 9^{1.4} = 3251 \text{ kPa}$$

The expansion backwards from $P_4 = P_1$ gives

$$P_3 = P_4 \times (v_4/v_3)^{k} = P_4 \times CR^{k} = 150 \text{ kPa} \times 14^{1.4} = 6034.9 \text{ kPa}$$

Combustion 2 to 3 at constant volume: $v_3 = v_2 \Rightarrow P_3 = P_2 \times (T_3/T_2)$

Energy Eq.: $u_3 = u_2 + q_H \quad \Rightarrow \quad q_H = C_v (T_3 - T_2)$

Solve for T_3 from process equation

$$T_3 = T_2 \times (P_3 / P_2) = 722.5 \text{ K} \times (6034.9 / 3251) = 1341.2 \text{ K}$$

Solve for q_H from the energy equation

$$q_H = C_v (T_3 - T_2) = 0.717 (1341.2 - 722.5) = \mathbf{443.6 \text{ kJ/kg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.111

Assume we change the Otto cycle in Problem 10.66 to an Atkinson cycle by keeping the same conditions and only increase the expansion to give a different state 4. Find the expansion ratio and the cycle efficiency.

Solution:

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 300 \times 10^{0.4} = 753.6 \text{ K}$$

$$P_2 = P_1 \times (v_1/v_2)^k = 95 \times 10^{1.4} = 2386 \text{ kPa}$$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$$T_3 = T_2 + q_H/C_v = 753.6 + 1300/0.717 = 2567 \text{ K}$$

$$P_3 = P_2 \times (T_3/T_2) = 2386\ (2567 / 753.6) = 8127 \text{ kPa}$$

The expansion should now bring pressure down so $P_4 = P_1$

$$P_4 = P_1 = P_3 \times (v_3/v_4)^k = P_3 \times CR^{-k} \Rightarrow CR = (P_3/P_4)^{1/k}$$

$$CR = (8127 / 95)^{0.71429} = \mathbf{24}$$

So now the efficiency becomes

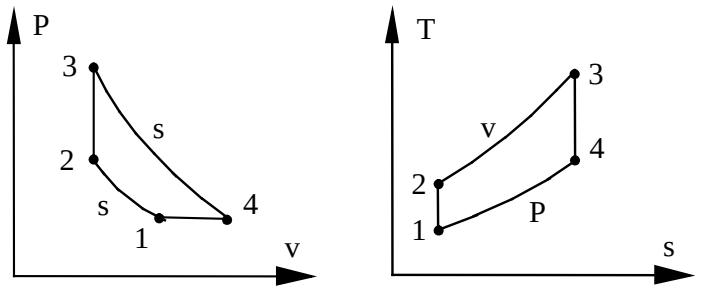
$$\eta = 1 - k \frac{CR - CR_1}{CR^k - CR_1^k} = 1 - 1.4 \frac{24 - 10}{24^{\,k} - 10^{\,k}} = \mathbf{0.675}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.112

Repeat Problem 10.73 assuming we change the Otto cycle to an Atkinson cycle by keeping the same conditions and only increase the expansion to give a different state 4.

Solution:



Compression: Reversible and adiabatic so constant s from Eq.6.24-25

$$P_2 = P_1(v_1/v_2)^k = 90 \text{ kPa } (7)^{1.4} = 1372 \text{ kPa}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 283.2 \text{ K} \times (7)^{0.4} = 616.6 \text{ K}$$

Combustion: constant volume

$$T_3 = T_2 + q_H/C_v = 616.6 + 1800/0.717 = \mathbf{3127\ K}$$

$$P_3 = P_2T_3/T_2 = 1372 \times 3127 / 616.6 = \mathbf{6958\ kPa}$$

The expansion should now bring pressure down so $P_4 = P_1$

$$P_4 = P_1 = P_3 \times (v_3/v_4)^k = P_3 \times CR^{-k} \Rightarrow CR = (P_3/P_4)^{1/k}$$

$$CR = (6958 / 90)^{0.71429} = \mathbf{22.32}$$

So now the efficiency and net work become

$$\eta_{TH} = 1 - k\frac{CR - CR_1}{CR^k - CR_1^k} = 1 - 1.4\frac{22.32 - 7}{22.32^{\,k} - 7^{\,k}} = \mathbf{0.654}$$

$$w_{net} = \eta_{TH} \times q_H = 0.654 \times 1800 \text{ kJ/kg} = 1177 \text{ kJ/kg}$$

Displacement (we take this as $v_4 - v_2$) and P_{meff}

$$v_1 = RT_1/P_1 = (0.287 \times 283.2)/90 = 0.9029 \text{ m}^3/\text{kg}$$

$$v_2 = (1/7)\, v_1 = 0.1290 \text{ m}^3/\text{kg}; \quad v_4 = 22.32\, v_2 = 2.879 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{NET}}{v_4 - v_2} = \frac{1177}{2.879 - 0.129} = \mathbf{428\ kPa}$$

Comment: The ratio $CR / CR_1 = 22.32/7$ is unrealistic large.

10.113

An Atkinson cycle has state 1 as 150 kPa, 300 K, compression ratio of 9 and expansion ratio of 14. Find the mean effective pressure.

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 300 \text{ K} \times 9^{0.4} = 722.5 \text{ K}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 150 \text{ kPa} \times 9^{1.4} = 3251 \text{ kPa}$$

The expansion backwards from $P_4 = P_1$ gives

$$P_3 = P_4 \times (v_4/v_3)^{k} = P_4 \times CR^{k} = 150 \text{ kPa} \times 14^{1.4} = 6034.9 \text{ kPa}$$

Combustion 2 to 3 at constant volume: $v_3 = v_2 \Rightarrow P_3 = P_2 \times (T_3/T_2)$

Energy Eq.: $u_3 = u_2 + q_H \quad \Rightarrow \quad q_H = C_v (T_3 - T_2)$

Solve for T_3 from process equation

$$T_3 = T_2 \times (P_3 / P_2) = 722.5 \text{ K} \times (6034.9 / 3251) = 1341.2 \text{ K}$$

Solve for q_H from the energy equation

$$q_H = C_v (T_3 - T_2) = 0.717 \text{ kJ/kg-K} (1341.2 - 722.5) \text{ K} = 443.6 \text{ kJ/kg}$$

The efficiency and net work become

$$\eta_{TH} = 1 - k \frac{CR - CR_1}{CR^k - CR_1^k} = 1 - 1.4 \frac{14 - 9}{14^k - 9^k} = 0.623$$

$$w_{net} = \eta_{TH} \times q_H = 0.623 \times 443.6 \text{ kJ/kg} = 276.4 \text{ kJ/kg}$$

Displacement (we take this as $v_4 - v_2$) and P_{meff}

$$v_1 = RT_1/P_1 = (0.287 \times 300)/150 = 0.574 \text{ m}^3/\text{kg}$$

$$v_2 = (1/9)\, v_1 = 0.06378 \text{ m}^3/\text{kg}; \quad v_4 = 14\, v_2 = 0.8929 \text{ m}^3/\text{kg}$$

$$P_{meff} = \frac{w_{NET}}{v_4 - v_2} = \frac{276.4}{0.8929 - 0.06378} = \mathbf{333 \text{ kPa}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.114

A Miller cycle has state 1 as 150 kPa, 300 K, compression ratio of 9 and expansion ratio of 14. If P_4 is 250 kPa find the heat release in the combustion.

Solution:

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 300 \text{ K} \times 9^{0.4} = 722.5 \text{ K}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 150 \text{ kPa} \times 9^{1.4} = 3251 \text{ kPa}$$

The expansion backwards from P_4 gives

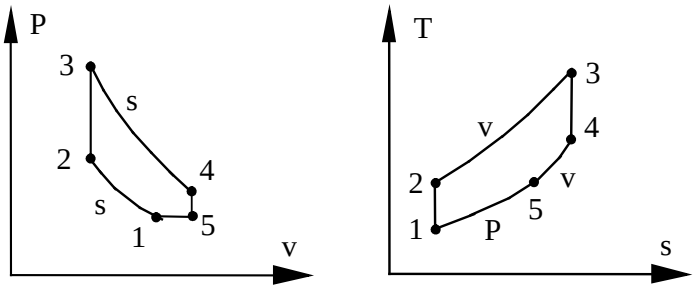
$$P_3 = P_4 \times (v_4/v_3)^{k} = P_4 \times CR^{k} = 250 \text{ kPa} \times 14^{1.4} = 10\,058 \text{ kPa}$$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$$T_3 = T_2 + q_H/C_v \quad \text{and} \quad P_3 = P_2 \times (T_3/T_2)$$

$$T_3 = T_2 \times (P_3 / P_2) = 722.5 \text{ K} \times (10\,058 / 3251) = 2235.3 \text{ K}$$

$$q_H = C_v (T_3 - T_2) = 0.717 \text{ kJ/kg-K} (2235.3 - 722.5) \text{ K} = \mathbf{1085 \text{ kJ/kg}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.115

A Miller cycle has state 1 as 150 kPa, 300 K, compression ratio of 9 and a heat release of 1000 kJ/kg. Find the needed expansion ratio so P_4 is 250 kPa.

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 300 \text{ K} \times 9^{0.4} = 722.5 \text{ K}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 150 \text{ kPa} \times 9^{1.4} = 3251 \text{ kPa}$$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$$T_3 = T_2 + q_H/C_v = 722.5 + 1000/0.717 = 2117 \text{ K}$$

$$P_3 = P_2 \times (T_3/T_2) = 3251 \text{ kPa } (2117 / 722.5) = 9526 \text{ kPa}$$

The expansion should now bring pressure down to P_4

$$P_4 = P_3 \times (v_3/v_4)^{k} = P_3 \times CR^{-k} \Rightarrow CR = (P_3 /P_4)^{1/k}$$

$$CR = (9526 / 250)^{0.71429} = \mathbf{13.5}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.116

In a Miller cycle assume we know state 1 (intake state) compression ratios CR_1 and CR. Find an expression for the minimum allowable heat release so $P_4 = P_5$ that is, it becomes an Atkinson cycle.

Compression: Reversible and adiabatic so constant s from Eq.6.24-25

$$T_2 = T_1(v_1/v_2)^{k-1} = T_1 CR_1^{\,k-1}$$

Combustion: constant volume

$$T_3 = T_2 + q_H/C_v \qquad \text{and} \qquad P_3 = P_2 T_3/T_2$$

The expansion should now bring pressure down so $P_4 = P_1$

$$P_4 = P_1 = P_3 \times (v_3/v_4)^k = P_3 \times CR^{-k}$$

From the ideal gas law and the above pressure relation we have

$$P_3 v_3 / P_1 v_1 = T_3 / T_1 = (P_3 / P_1) CR_1 = CR^k\, CR_1$$

so now substitute

$$T_3 = T_2 + q_H/C_v = T_1 CR_1^{\,k-1} + q_H/C_v$$

to get

$$T_1 CR_1^{\,k-1} + q_H/C_v = T_1\, CR^k\, CR_1$$

and now solve for q_H

$$q_H = C_v\, T_1\, [CR^k\, CR_1 - CR_1^{\,k-1}] = \mathbf{C_v\, T_1\, [\, CR^k - CR_1^{\,k}\,] / CR_1}$$

10.117

A Rankine steam power plant should operate with a high pressure of 3 MPa, a low pressure of 10 kPa, and the boiler exit temperature should be 500°C. The available high-temperature source is the exhaust of 175 kg/s air at 600°C from a gas turbine. If the boiler operates as a counterflowing heat exchanger where the temperature difference at the pinch point is 20°C, find the maximum water mass flow rate possible and the air exit temperature.

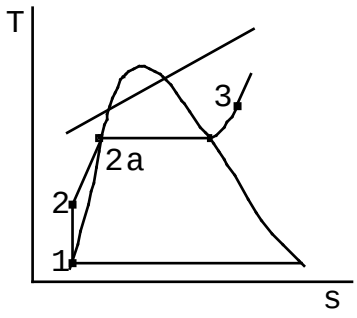
Solution:

C.V. Pump

$w_P = h_2 - h_1 = v_1(P_2 - P_1)$

$= 0.00101(3000 - 10) = 3.02$ kJ/kg

$h_2 = h_1 + w_P = 191.83 + 3.02 = 194.85$ kJ/kg

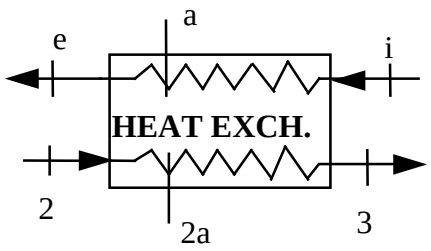


Heat exchanger water states

State 2a: $T_{2a} = T_{SAT} = 233.9$ °C

$h_{2a} = 1008.42$ kJ/kg

State 3: $h_3 = 3456.5$ kJ/kg



Heat exchanger air states

inlet: $h_{air,in} = 903.16$ kJ/kg

State 2a: $h_{air}(T_{2a} + 20) = 531.28$ kJ/kg

Air temperature should be 253.9°C at the point where the water is at state 2a.

C.V. Section 2a-3, i-a

$$\dot{m}_{H_2O}(h_3 - h_{2a}) = \dot{m}_{air}(h_i - h_a)$$

$$\dot{m}_{H_2O} = 175 \frac{903.16 - 531.28}{3456.5 - 1008.42} = \mathbf{26.584\ kg/s}$$

Take C.V. Total: $\dot{m}_{H_2O}(h_3 - h_2) = \dot{m}_{air}(h_i - h_e)$

$\Rightarrow \quad h_e = h_i - \dot{m}_{H_2O}(h_3 - h_2)/\dot{m}_{air}$

$= 903.6 - 26.584(3456.5 - 194.85)/175 = 408.13$ kJ/kg

$\Rightarrow \quad T_e = 406.7$ K = **133.6 °C**, $T_e > T_2 = 46.5$ °C OK.

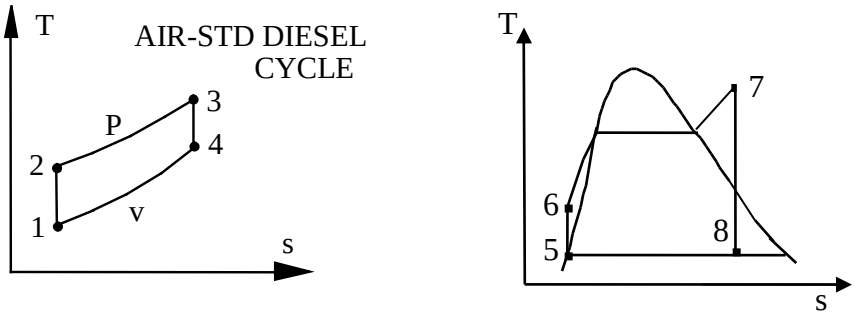
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.118

A simple Rankine cycle with R-410A as the working fluid is to be used as a bottoming cycle for an electrical generating facility driven by the exhaust gas from a Diesel engine as the high temperature energy source in the R-410A boiler. Diesel inlet conditions are 100 kPa, 20°C, the compression ratio is 20, and the maximum temperature in the cycle is 2800 K. The R-410A leaves the bottoming cycle boiler at 80°C, 4 MPa and the condenser pressure is 1800 kPa. The power output of the Diesel engine is 1 MW. Assuming ideal cycles throughout, determine

a. The flow rate required in the diesel engine.

b. The power output of the bottoming cycle, assuming that the diesel exhaust is cooled to 200°C in the R-410A boiler.



Diesel cycle information given means: $\dot{W}_{DIESEL} = 1$ MW

$P_1 = 100$ kPa, $T_1 = 20\ ^oC$, $CR = v_1/v_2 = 20$, $T_3 = 2800$ K

Consider the Diesel cycle

$T_2 = T_1(v_1/v_2)^{k-1} = 293.2\ K\ (20)^{0.4} = 971.8$ K

$P_2 = P_1(v_1/v_2)^k = 100\ kPa\ (20)^{1.4} = 6629$ kPa

$q_H = C_{P0}(T_3 - T_2) = 1.004$ kJ/kg-K(2800 - 971.8) K = 1835.5 kJ/kg

$$v_1 = \frac{0.287 \times 293.2}{100} = 0.8415\ m^3/kg, \quad v_2 = \frac{0.8415}{20} = 0.04208\ m^3/kg$$

$v_3 = v_2(T_3/T_2) = 0.04208\ m^3/kg\ (2800/971.8) = 0.12124\ m^3/kg$

$$T_4 = T_3\left(\frac{v_3}{v_4}\right)^{k-1} = 2800\ K\left(\frac{0.12124}{0.8415}\right)^{0.4} = 1290\ K$$

$q_L = 0.717(293.15 - 1290) = -714.7$ kJ/kg

$w_{NET} = 1835.5 - 714.7 = 1120.76$ kJ/kg

$\dot{m}_{AIR} = \dot{W}_{NET}/w_{NET} = 1000$ kW/1120.76 kJ/kg = **0.892 kg/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Rankine cycle information given means:

Boiler exit state: $T_7 = 80^oC$, $P_7 = 4$ MPa,

Condenser: $P_8 = P_5 = 1800$ kPa, $T_5 = 28.22^oC$, $h_5 = h_f = 103.1$ kJ/kg

Consider the Rankine cycle

$s_8 = s_7 = 1.0028$ => Sup. vapor $T_8 = 32.92^oC$, $h_8 = 290.6$ kJ/kg

$w_T = h_7 - h_8 = 311.48 - 290.6 = 20.88$ kJ/kg

$-w_P = v_5(P_6 - P_5) = 0.0009595\ m^3/kg\ (4000 - 1800)$ kPa $= 2.11$ kJ/kg

$h_6 = h_5 - w_P = 103.1 + 2.11 = 105.21$ kJ/kg

$q_H = h_7 - h_6 = 311.48 - 105.21 = 206.27$ kJ/kg

Connecting the two cycles.

$\dot{Q}_H$ available from Diesel exhaust flow cooled to 200 ^oC:

$\dot{Q}_H = 0.892$ kg/s $\times$ 1.004 kJ/kg-K (1290 - 473.2) K = 731 kW

$\Rightarrow \dot{m}_{R\text{-}410a} = \dot{Q}_H / q_H = 731$ kW /206.27 kJ/kg = 3.544 kg/s

$\dot{W}_{R\text{-}410a} = 3.544$ kg/s (20.88 - 2.11) kJ/kg = **66.5 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.119

A small utility gasoline engine of 250 cc runs at 1500 RPM with a compression ratio of 7:1. The inlet state is 75 kPa, 17^{o}C and the combustion adds 1500 kJ/kg to the charge. This engine runs a heat pump using R-410A with high pressure of 4 MPa and an evaporator operating at 0^{o}C. Find the rate of heating the heat pump can deliver.

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2 = 7$

$$\eta_{TH} = 1 - r_{1\text{-}k} = 1 - 7^{-0.4} = 0.5408$$

$$w_{net} = \eta_{TH} \times q_H = 0.5408 \times 1500 = 811.27 \text{ kJ/kg}$$

We also need specific volume to evaluate Eqs.10.9 to 10.11

$$v_1 = RT_1 / P_1 = 0.287 \text{ kJ/kg-K} \times 290 \text{ K} / 75 \text{ kPa} = 1.1097 \text{ m}^3\text{/kg}$$

$$v_2 = v_1/CR = 0.15853 \text{ m}^3\text{/kg}$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = \frac{811.27}{1.097 - 0.15853} \frac{\text{kJ/kg}}{\text{m}^3\text{/kg}} = 852.9 \text{ kPa}$$

Now we can find the power from Eq.10.11 (assume 4 stroke engine)

$$\dot{W} = P_{meff} V_{displ} \frac{RPM}{60} \frac{1}{2} = 852.9 \times 2.5 \times 10^{-4} \times \frac{1500}{60} \times \frac{1}{2} = 2.665 \text{ kW}$$

For the refrigeration cycle we have:

State 1: $h_1 = 279.12$ kJ/kg, $s_1 = 1.0368$ kJ/kgK

State 2: 4 MPa, $s_2 = s_1$ interpolate => $h_2 = 323.81$ kJ/kg

State 3: 4 MPa interpolate $h_3 = 171.62$ kJ/kg

$$\beta_{HP} = \frac{q_H}{w_C} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{323.81 - 171.62}{323.81 - 279.12} = 3.405$$

The work out of the heat engine equals the input to the heat pump

$$\dot{Q}_H = \beta_{HP} \dot{W} = 3.405 \times 2.665 \text{ kW} = \mathbf{9.07 \text{ kW}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.120

Can the combined cycles in the previous problem deliver more heat than what comes from the R-410A? Find any amounts if so by assuming some conditions.

The hot exhaust gases from the gasoline engine can also be used and as the heat pump delivers heat at a temperature that equals the saturation T at 4 MPa which is 61.9^{o}C, the exhaust gas can be cooled to that. Not all the heat out of the heat engine is exhaust gas, part of $\dot{Q}_L$ is heat transfer rejected by the cooling (air or coolant). So as the engine produces 2.66 kW with an efficiency of 54% we must have:

$$\dot{Q}_{H\ fuel} = \dot{W} / \eta_{TH} = 2.66\ kW / 0.54 = 4.93\ kW \quad \text{input so}$$

$$\dot{Q}_{L\ engine} = \dot{Q}_{H\ fuel} - \dot{W} = 4.93 - 2.66 = 2.3\ kW$$

Generally half of this is exhaust gas and the other half heat transfer. So we can potentially get an additional 1 kW to heat with from the exhaust gas alone in addition to the heat pump output.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.121

The power plant shown in Fig. 10.24 combines a gas-turbine cycle and a steam-turbine cycle. The following data are known for the gas-turbine cycle. Air enters the compressor at 100 kPa, 25°C, the compressor pressure ratio is 14, the heater input rate is 60 MW; the turbine inlet temperature is 1250°C, the exhaust pressure is 100 kPa; the cycle exhaust temperature from the heat exchanger is 200°C. The following data are known for the steam-turbine cycle. The pump inlet state is saturated liquid at 10 kPa, the pump exit pressure is 12.5 MPa; turbine inlet temperature is 500°C. Determine

a. The mass flow rate of air in the gas-turbine cycle.
b. The mass flow rate of water in the steam cycle.
c. The overall thermal efficiency of the combined cycle.

a) From Air Tables, A.7: $P_{r1} = 1.0913$, $h_1 = 298.66$, $h_5 = 475.84$ kJ/kg

$$s_2 = s_1 \Rightarrow P_{r2S} = P_{r1}(P_2/P_1) = 1.0913 \times 14 = 15.2782$$

$$T_2 = 629 \text{ K}, \quad h_2 = 634.48 \text{ kJ/kg}$$

$$w_C = h_1 - h_2 = 298.66 - 634.48 = -335.82 \text{ kJ/kg}$$

At $T_3 = 1523.2$ K: $P_{r3} = 515.493$, $h_3 = 1663.91$ kJ/kg

$$\dot{m}_{AIR} = \dot{Q}_H/(h_3 - h_2) = \frac{60\,000}{1663.91 - 634.48} = \mathbf{58.28\ kg/s}$$

b) $$P_{r4S} = P_{r3}(P_4/P_3) = 515.493(1/14) = 36.8209$$

$$\Rightarrow T_4 = 791 \text{ K}, \quad h_4 = 812.68 \text{ kJ/kg}$$

$$w_{T\,gas} = h_3 - h_4 = 1663.91 - 812.68 = 851.23 \text{ kJ/kg}$$

Steam cycle: $-w_P \approx 0.00101\ m^3/kg\ (12500 - 10)\ kPa = 12.615$ kJ/kg

$$h_6 = h_9 - w_P = 191.83 + 12.615 = 204.45 \text{ kJ/kg}$$

At 12.5 MPa, 500 °C: $h_7 = 3341.1$ kJ/kg, $s_7 = 6.4704$ kJ/kg K

$$\dot{m}_{H_2O} = \dot{m}_{AIR}\frac{h_4 - h_5}{h_7 - h_6} = 58.28\,\frac{812.68 - 475.84}{3341.1 - 204.45} = \mathbf{6.259\ kg/s}$$

c) $$s_8 = s_7 = 6.4704 = 0.6492 + x_8 \times 7.501, \quad x_8 = 0.7761$$

$$h_8 = 191.81 + 0.7761 \times 2392.8 = 2048.9 \text{ kJ/kg}$$

$$w_{T\,steam} = h_7 - h_8 = 3341.1 - 2048.9 = 1292.2 \text{ kJ/kg}$$

10.122

Consider the Brayton cycle in Problem 10.28. Find all the flows and fluxes of exergy and find the overall cycle second-law efficiency. Assume the heat transfers are internally reversible processes, and we neglect any external irreversibility.

Solution:

Efficiency is from Eq.10.1

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 16^{-0.4/1.4} = 0.547$$

from the required power we can find the needed heat transfer

$$\dot{Q}_H = \dot{W}_{net} / \eta = \frac{14\,000}{0.547} = 25\,594 \text{ kW}$$

$$\dot{m} = \dot{Q}_H / q_H = 25\,594 \text{ kW} / 1160 \text{ kJ/kg} = \mathbf{22.064 \text{ kg/s}}$$

Temperature after compression is

$$T_2 = T_1 \, r_p^{(k-1)/k} = 290 \times 16^{0.4/1.4} = 640.35 \text{ K}$$

The highest temperature is after combustion

$$T_3 = T_2 + q_H/C_p = 640.35 + \frac{1160}{1.004} = 1795.7 \text{ K}$$

For the exit flow I need the exhaust temperature

$$T_4 = T_3 \; r_p^{-\frac{k-1}{k}} = 1795.7 \times 16^{-0.2857} = 813.25 \text{ K}$$

$\eta_{II} = \dot{W}_{NET}/\dot{\Phi}_H$ since the low T exergy flow out is lost

The high T exergy input from combustion is

$$\dot{\Phi}_H = \dot{m}(\psi_3 - \psi_2) = \dot{m}[h_3 - h_2 - T(s_3 - s_2)]$$

$$= 22.064 \, [1160 - 298 \times 1.004 \ln (\frac{1795.7}{640.35})] = \mathbf{18\,784 \text{ kW}}$$

$$\eta_{II} = \dot{W}_{NET}/\dot{\Phi}_H = 14\,000 / 18\,784 = \mathbf{0.745}$$

$$\dot{\Phi}_{flow\ in} = \dot{m}(\psi_1 - \psi_o) = \dot{m}[h_1 - h_o - T_o(s_1 - s_o)]$$

$$= 22.064 \, [\, 1.004(17 - 25) - 298 \times 1.004 \ln (\frac{290}{298}) \,] = \mathbf{2.5 \text{ kW}}$$

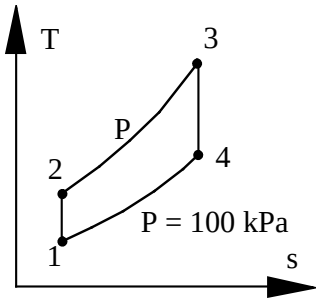
$$\dot{\Phi}_{flow\ out} = \dot{m}(\psi_4 - \psi_o) = \dot{m}[h_4 - h_o - T(s_4 - s_o)]$$

$$= 22.064 \, [\, 1.004(813 - 298) - 298 \times 1.004 \ln (\frac{813}{298}) \,] = \mathbf{4545 \text{ kW}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.123

A Brayton cycle has a compression ratio of 15:1 with a high temperature of 1600 K and an inlet state of 290 K, 100 kPa. Use cold air properties to find the specific net work output and the second law efficiency if we neglect the "value" of the exhaust flow.



Brayton cycle so this means:

Minimum T: $T_1 = 290$ K

Maximum T: $T_3 = 1600$ K

Pressure ratio: $P_2/P_1 = 15$

Solve using constant C_{P0}

Compression in compressor: $s_2 = s_1 \Rightarrow$ Implemented in Eq.6.23

$$T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 290\ \text{K}\ (15)^{0.286} = 628.65\ \text{K}$$

Energy input is from the combustor

$$q_H = h_3 - h_2 = C_{P0}(T_3 - T_2) = 1.004\ \text{kJ/kg-K}\ (1600 - 628.65)\ \text{K}$$
$$= 975.2\ \text{kJ/kg}$$

Do the overall cycle efficiency and net work

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 15^{-0.4/1.4} = \mathbf{0.5387}$$

$$w_{NET} = \eta\, q_H = 0.5387 \times 975.2 = 525.34\ \text{kJ/kg}$$

Notice the q_H does not come at a single T so neglecting external irreversibility we get

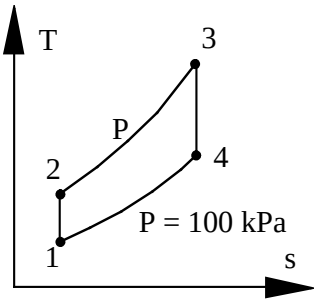
$$\Phi_{qH} = \text{increase in flow exergy} = \psi_3 - \psi_2 = h_3 - h_2 - T_o(s_3 - s_2)$$
$$= q_H - T_o\, C_P \ln(T_3/T_2) = 975.2 - 298.15 \times 1.004 \ln\left(\frac{1600}{628.65}\right)$$
$$= 695.56\ \text{kJ/kg}$$

$$\eta_{II} = \frac{w_{net}}{\psi_3 - \psi_2} = \frac{525.34}{695.56} = \mathbf{0.755}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.124

Reconsider the previous problem and find the second law efficiency if you do consider the "value" of the exhaust flow.



Brayton cycle so this means:

Minimum T: $T_1 = 290$ K

Maximum T: $T_3 = 1600$ K

Pressure ratio: $P_2/P_1 = 15$

Solve using constant C_{P0}

Compression in compressor: $s_2 = s_1 \Rightarrow$ Implemented in Eq.6.23

$$T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 290(15)^{0.286} = 628.65 \text{ K}$$

Energy input is from the combustor

$$q_H = h_3 - h_2 = C_{P0}(T_3 - T_2) = 1.004\ (1600 - 628.65) = 975.2 \text{ kJ/kg}$$

Do the overall cycle thermal efficiency and net work

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 15^{-0.4/1.4} = \mathbf{0.5387}$$

$$w_{NET} = \eta\, q_H = 0.5387 \times 975.2 = 525.34 \text{ kJ/kg}$$

Notice the q_H does not come at a single T so neglecting external irreversibility we get

$$\Phi_{qH} = \text{increase in flow exergy} = \psi_3 - \psi_2 = h_3 - h_2 - T_o(s_3 - s_2)$$

$$= q_H - T_o\, C_P \ln(T_3/T_2) = 975.2 - 298.15 \times 1.004 \ln\left(\frac{1600}{628.65}\right)$$

$$= 695.56 \text{ kJ/kg}$$

$$T_4 = T_3\,(P_4/P_3)^{\frac{k-1}{k}} = 1600 \text{ K} \times (1/15)^{0.286} = 738 \text{ K}$$

$$\Phi_{qL} = \psi_4 - \psi_1 = h_4 - h_1 - T_o(s_4 - s_1) = C_P(T_4 - T_1) - T_o\, C_P \ln\frac{T_4}{T_1}$$

$$= 1.004 \text{ kJ/kg-K} \times [\ 738 - 290 - 298 \ln(\tfrac{738}{290})\ ] \text{ K} = 170.33 \text{ kJ/kg}$$

$$\eta_{II} = \frac{w_{net}}{\Phi_{qH} - \Phi_{qL}} = \frac{525.34}{695.56 - 170.33} = \mathbf{1}$$

Why is it 1?, the cycle is reversible so we could have said that right away.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.125

For Problem 10.117, determine the change of exergy of the water flow and that of the air flow. Use these to determine a second law efficiency for the boiler heat exchanger.

From solution to 10.117:

$\dot{m}_{H2O}$ = 26.584 kg/s, h_2 = 194.85 kJ/kg, s_2 = 0.6587 kJ/kg K

h_3 = 3456.5 kJ/kg, s_3 = 7.2338, $s°_{Ti}$ = 7.9820, $s°_{Te}$ = 7.1762 kJ/kg K

h_i = 903.16 kJ/kg, h_e = 408.13 kJ/kg

$\psi_3 - \psi_2 = h_3 - h_2 - T_0(s_3 - s_2)$ = 1301.28 kJ/kg

$\psi_i - \psi_e = h_i - h_e - T_0(s°_{Ti} - s°_{Te})$ = 254.78 kJ/kg

$$\eta_{II} = \frac{(\psi_3 - \psi_2)\dot{m}_{H2O}}{(\psi_i - \psi_e)\dot{m}_{air}} = \frac{1301.28 \times 26.584}{254.78 \times 175} = \mathbf{0.776}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.126

Determine the second law efficiency of an ideal regenerator in the Brayton cycle.

The ideal regenerator has no temperature difference between the two flows and is therefore reversible. Its second law efficiency is **100%**.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.127

Assume a regenerator in a Brayton cycle has an efficiency of 75%. Find an expression for the second law efficiency.

To do this, assume the pressure is constant in the two flows so we do not have any pressure loss. The change in enthalpy and entropy is then only due to changes in temperature for the two flows.

$$\eta_{II} = \frac{\psi_x - \psi_2}{\psi_4 - \psi_2} = \frac{h_x - h_2 - T_o(s_x - s_2)}{h_4 - h_2 - T_o(s_4 - s_2)}$$

$$= \frac{C_P\,(T_x - T_2) - T_o\,C_P \ln(T_x/T_2)}{C_P\,(T_4 - T_2) - T_o\,C_P \ln(T_4/T_2)}$$

$$= \frac{T_x - T_2 - T_o\ \ln(T_x/T_2)}{T_4 - T_2 - T_o\ \ln(T_4/T_2)}$$

Finally we have

$$\eta_{II} = \frac{\eta_{reg} - a \ln(T_x/T_2)}{1 - a \ln(T_4/T_2)}$$

where a is defined as

$$a = \frac{T_o}{T_4 - T_2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.128

The Brayton cycle in Problem 10.19 had a heat addition of 800 kJ/kg. What is the exergy increase in the heat addition process?

Solution:

Combustion: $h_3 = h_2 + q_H$; $\quad {}_2w_3 = 0$ and $T_{max} = T_3 = 1400$ K

$T_2 = T_3 - q_H/C_P = 1400$ K – 800 kJ/kg /1.004 kJ/kg-K = 603.2 K

Now the exergy increase from 2 to 3 becomes ($P_3 = P_2$)

$$\psi_3 - \psi_2 = h_3 - h_2 - T_0(s_3 - s_2) = q_H - T_0 C_P \ln(T_3/T_2)$$

$$= 800 - 298.15 \times 1.004 \ln \left(\frac{1400}{603.2} \right)$$

$$= \mathbf{547.96\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.129

The conversion efficiency of the Brayton cycle in Eq.10.1 was done with cold air properties. Find a similar formula for the second law efficiency assuming the low T heat rejection is assigned zero exergy value.

The thermal efficiency (first law) is Eq.10.1

$$\eta_{TH} = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k}$$

The corresponding 2nd law efficiency is

$$\eta_{II} = \frac{w_{net}}{\Phi_H} = \frac{h_3 - h_2 - (h_4 - h_1)}{h_3 - h_2 - T_o(s_3 - s_2)}$$

where we used Φ_H = increase in flow exergy = $\psi_3 - \psi_2 = h_3 - h_2 - T_o(s_3 - s_2)$. Now divide the difference $h_3 - h_2$ out to get

$$\eta_{II} = \frac{1 - \dfrac{h_4 - h_1}{h_3 - h_2}}{1 - T_o(s_3 - s_2)/(h_3 - h_2)} = \frac{\eta_{TH}}{1 - T_o(s_3 - s_2)/(h_3 - h_2)}$$

$$= \frac{\eta_{TH}}{1 - T_o \dfrac{C_P \ln(T_3 / T_2)}{C_P (T_3 - T_2)}}$$

$$= \frac{\eta_{TH}}{1 - T_o \dfrac{\ln(T_3 / T_2)}{T_3 - T_2}}$$

Comment: Due to the temperature sensitivity of Φ_H the temperatures do not reduce out from the expression.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.130

Redo the previous problem for a large stationary Brayton cycle where the low T heat rejection is used in a process application and thus has a non-zero exergy.

The thermal efficiency (first law) is Eq.10.1

$$\eta_{TH} = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k}$$

The corresponding 2nd law efficiency is

$$\eta_{II} = \frac{w_{net}}{\Phi_H - \Phi_L} = \frac{h_3 - h_2 - (h_4 - h_1)}{h_3 - h_2 - T_o(s_3 - s_2)}$$

where we used

Φ_H = increase in flow exergy = $\psi_3 - \psi_2 = h_3 - h_2 - T_o(s_3 - s_2)$.

Φ_L = rejection of flow exergy = $\psi_4 - \psi_1 = h_4 - h_1 - T_o(s_4 - s_1)$.

Now divide all terms with the difference $h_3 - h_2$ to get

$w_{net}/(h_3 - h_2) = \eta_{TH}$;

$$\Phi_H/(h_3 - h_2) = 1 - T_o(s_3 - s_2)(h_3 - h_2) = 1 - T_o \ln(T_3/T_2)\,(T_3 - T_2)^{-1}$$

$$\Phi_L/(h_3 - h_2) = \frac{h_4 - h_1}{h_3 - h_2}\left[\,1 - T_o\,\frac{s_4 - s_1}{h_4 - h_1}\,\right] = (1 - \eta_{TH})\left[1 - T_o\,\frac{\ln T_4/T_1}{T_4 - T_1}\,\right]$$

Substitute all terms to get

$$\eta_{II} = \frac{\eta_{TH}}{1 - T_o\dfrac{\ln(T_3/T_2)}{T_3 - T_2} - (1 - \eta_{TH})\left[1 - T_o\,\dfrac{\ln(T_4/T_1)}{T_4 - T_1}\right]}$$

Comment: Due to the temperature sensitivity of Φ_H and Φ_L the temperatures do not reduce out from the expression.

10.131

Solve Problem 10.19 with variable specific heats using Table A.7.

A Brayton cycle inlet is at 300 K, 100 kPa and the combustion adds 800 kJ/kg. The maximum temperature is 1400 K due to material considerations. What is the maximum allowed compression ratio? For this compression ratio calculate the net work and cycle efficiency using cold air properties.

Solution:

Combustion: $h_3 = h_2 + q_H$; $\quad {}_2w_3 = 0$ and $T_{max} = T_3 = 1400$ K

$h_2 = h_3 - q_H = 1515.27 - 800 = 715.27$ kJ/kg

From Table A.7.1

$T_2 \approx 701.6$ K; $\quad s^o_{T2} = 7.74251$; $\quad T_1 = 300$ K; $\quad s^o_{T1} = 6.86926$ kJ/kg K

Reversible adiabatic compression leads to constant s, from Eq.6.19:

$P_2 / P_1 = \exp[\ (s^o_{T2} - s^o_{T1})/R\ ] = \exp(3.04268) =$ **20.96**

Reversible adiabatic expansion leads to constant s, from Eq.6.19

$s^o_{T4} = s^o_{T3} + R \ln(P_4 / P_3) = 8.52891 + 0.287 \ln (1/20.96) = 7.65568$ kJ/kgK

From Table A.7.1 by linear interpolation $\quad T_4 \approx 646.85$ K, $\quad h_4 = 656.81$ kJ/kg

$w_T = h_3 - h_4 = 1515.27 - 656.81 = 858.46$ kJ/kg

$w_C = h_2 - h_1 = 715.27 - 300.47 = 414.8$ kJ/kg

$w_{net} = w_T - w_C = 858.46 - 414.8 =$ **443.7 kJ/kg**

$\eta = w_{net} / q_H = 443.7 / 800 =$ **0.55**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.132

Do Problem 10.28 with properties from table A.7.1 instead of cold air properties.

Solution:
With the variable specific heat we must go through the processes one by one to get net work and the highest temperature T_3.

From A.7.1: $h_1 = 290.43$ kJ/kg, $s^o_{T1} = 6.83521$ kJ/kg K

The compression is reversible and adiabatic so constant s. From Eq.6.19

$$s_2 = s_1 \Rightarrow s^o_{T2} = s^o_{T1} + R\ln(P_2/P_1) = 6.83521 + 0.287 \ln 16 = 7.63094$$

$$\Rightarrow T_2 = 631.9 \text{ K}, \quad h_2 = 641 \text{ kJ/kg}$$

Energy equation with compressor work in

$$w_C = -{}_1w_2 = h_2 - h_1 = 641 - 290.43 = 350.57 \text{ kJ/kg}$$

Energy Eq. combustor: $h_3 = h_2 + q_H = 641 + 1160 = 1801$ kJ/kg

State 3: (P, h): $\mathbf{T_3 = 1635.7\ K}$, $s^o_{T3} = 8.71738$ kJ/kg K

The expansion is reversible and adiabatic so constant s. From Eq.6.19

$$s_4 = s_3 \Rightarrow s^o_{T4} = s^o_{T3} + R\ln(P_4/P_3) = 8.71738 + 0.287\ln(1/16) = 7.92165$$

$$\Rightarrow T_4 = 827.3 \text{ K}, \quad h_4 = 852.31 \text{ kJ/kg}$$

Energy equation with turbine work out

$$w_T = h_3 - h_4 = 1801 - 852.31 = 948.69 \text{ kJ/kg}$$

Now the net work is

$$w_{net} = w_T - w_C = 948.69 - 350.57 = 598.12 \text{ kJ/kg}$$

The total required power requires a mass flow rate as

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{14\,000}{598.12}\frac{\text{kW}}{\text{kJ/kg}} = \mathbf{23.41\ kg/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.133

Repeat Problem 10.36, but assume that the compressor has an efficiency of 82%, that both turbines have efficiencies of 87%, and that the regenerator efficiency is 70%.

a) From solution 10.36: $T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300\ \text{K}\ (6)^{0.286} = 500.8\ \text{K}$

$$-w_C = -w_{12} = C_{P0}(T_2 - T_1) = 1.004\ \text{kJ/kg-K}\ (500.8 - 300)\ \text{K} = 201.6\ \text{kJ/kg}$$

$$-w_C = -w_{SC}/\eta_{SC} = 201.6/0.82 = 245.8\ \text{kJ/kg} = w_{T1}$$

$$= C_{P0}(T_4 - T_5) = 1.004\ \text{kJ/kg-K}\ (1600\ \text{K} - T_5) \quad \Rightarrow \quad T_5 = 1355.2\ \text{K}$$

$$w_{ST1} = w_{T1}/\eta_{ST1} = 245.8/0.87 = 282.5\ \text{kJ/kg}$$

$$= C_{P0}(T_4 - T_{5S}) = 1.004(1600 - T_{5S}) \quad \Rightarrow \quad T_{5S} = 1318.6\ \text{K}$$

$$s_{5S} = s_4 \Rightarrow P_5 = P_4(T_{5S}/T_4)^{\frac{k}{k-1}} = 600\left(\frac{1318.6}{1600}\right)^{3.5} = \mathbf{304.9\ kPa}$$

b) $P_6 = 100\ \text{kPa}, \quad s_{6S} = s_5$

$$T_{6S} = T_5\left(\frac{P_6}{P_5}\right)^{\frac{k-1}{k}} = 1355.2\left(\frac{100}{304.9}\right)^{0.286} = 985.2\text{K}$$

$$w_{ST2} = C_{P0}(T_5 - T_{6S}) = 1.004(1355.2 - 985.2) = 371.5\ \text{kJ/kg}$$

$$w_{T2} = \eta_{ST2} \times w_{ST2} = 0.87 \times 371.5 = \mathbf{323.2\ kJ/kg}$$

$$323.2 = C_{P0}(T_5 - T_6) = 1.004(1355.2 - T_6) \Rightarrow T_6 = 1033.3\text{K}$$

$$\dot{m} = \dot{W}_{NET}/w_{NET} = 150/323.2 = \mathbf{0.464\ kg/s}$$

c) $w_C = 245.8 = C_{P0}(T_2 - T_1) = 1.004(T_2 - 300) \Rightarrow T_2 = 544.8\ \text{K}$

$$\eta_{REG} = \frac{h_3 - h_2}{h_6 - h_2} = \frac{T_3 - T_2}{T_6 - T_2} = \frac{T_3 - 544.8}{1033.3 - 544.8} = 0.7$$

$$\Rightarrow T_3 = 886.8\ \text{K}$$

$$q_H = C_{P0}(T_4 - T_3) = 1.004(1600 - 886.8) = 716\ \text{kJ/kg}$$

$$\eta_{TH} = w_{NET}/q_H = 323.2/716 = \mathbf{0.451}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.134

Consider a gas turbine cycle with two stages of compression and two stages of expansion. The pressure ratio across each compressor stage and each turbine stage is 8 to 1. The pressure at the entrance of the first compressor is 100 kPa, the temperature entering each compressor is 20°C, and the temperature entering each turbine is 1100°C. A regenerator is also incorporated into the cycle and it has an efficiency of 70%. Determine the compressor work, the turbine work, and the thermal efficiency of the cycle.

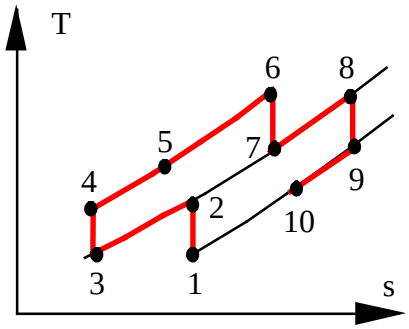
$P_2/P_1 = P_4/P_3 = P_6/P_7 = P_8/P_9 = 8.0$

$P_1 = 100$ kPa

$T_1 = T_3 = 20\ ^oC, \quad T_6 = T_8 = 1100\ ^oC$

Cold air and $s_2 = s_1$ and $s_4 = s_3$

$$T_4 = T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 293.15(8)^{0.286} = 531 \text{ K}$$



Total $-w_C = 2 \times (-w_{12}) = 2C_{P0}(T_2 - T_1) = 2 \times 1.004(531 - 293.15) =$ **477.6 kJ/kg**

Also $s_6 = s_7$ and $s_8 = s_9$: $\Rightarrow \quad T_7 = T_9 = T_6\left(\frac{P_7}{P_6}\right)^{\frac{k-1}{k}} = 1373.15\left(\frac{1}{8}\right)^{0.286} = 758$ K

Total $w_T = 2 \times w_{67} = 2C_{P0}(T_6 - T_7) = 2 \times 1.004(1373.15 - 758) = 1235.2$ kJ/kg

$w_{NET} = 1235.2 - 477.6 = 757.6$ kJ/kg

Ideal regenerator: $T_5 = T_9$, $T_{10} = T_4$ so the actual one has

$$\eta_{REG} = \frac{h_5 - h_4}{h_9 - h_4} = \frac{T_5 - T_4}{T_9 - T_4} = \frac{T_5 - 531}{758 - 531} = 0.7 \qquad \Rightarrow T_5 = 689.9 \text{ K}$$

$$\Rightarrow q_H = (h_6 - h_5) + (h_8 - h_7) = C_{P0}(T_6 - T_5) + C_{P0}(T_8 - T_7)$$
$$= 1.004(1373.15 - 689.9) + 1.004\ (1373.15 - 758)$$
$$= 1303.6 \text{ kJ/kg}$$

$\eta_{TH} = w_{NET}/q_H = 757.6/1303.6 =$ **0.581**

10.135

A gas turbine cycle has two stages of compression, with an intercooler between the stages. Air enters the first stage at 100 kPa, 300 K. The pressure ratio across each compressor stage is 5 to 1, and each stage has an isentropic efficiency of 82%. Air exits the intercooler at 330 K. The maximum cycle temperature is 1500 K, and the cycle has a single turbine stage with an isentropic efficiency of 86%. The cycle also includes a regenerator with an efficiency of 80%. Calculate the temperature at the exit of each compressor stage, the second-law efficiency of the turbine and the cycle thermal efficiency.

State 1: $P_1 = 100$ kPa, $T_1 = 300$ K State 7: $P_7 = P_o = 100$ kPa

State 3: $T_3 = 330$ K; State 6: $T_6 = 1500$ K, $P_6 = P_4$

$P_2 = 5\ P_1 = 500$ kPa; $P_4 = 5\ P_3 = 2500$ kPa

Ideal compression $T_{2s} = T_1\ (P_2/P_1)^{(k-1)/k} = 475.4$ K

1st Law: $q + h_i = h_e + w$; $q = 0$ => $w_{c1} = h_1 - h_2 = C_P(T_1 - T_2)$

$w_{c1\,s} = C_P(T_1 - T_{2s}) = -176.0$ kJ/kg, $w_{c1} = w_{c1\,s}/\eta = -214.6$

$T_2 = T_1 - w_{c1}/C_P =$ **513.9 K**

$T_{4s} = T_3\ (P_4/P_3)^{(k-1)/k} = 475.4$ K

$w_{c2\,s} = C_P(T_3 - T_{4s}) = -193.6$ kJ/kg; $w_{c2} = -236.1$ kJ/kg

$T_4 = T_3 - w_{c2}/C_P =$ **565.2 K**

Ideal Turbine (reversible and adiabatic)

$T_{7s} = T_6(P_7/P_6)^{(k-1)/k} = 597.4$ K => $w_{Ts} = C_P(T_6 - T_{7s}) = 905.8$ kJ/kg

1st Law Turbine: $q + h_6 = h_7 + w$; $q = 0$

$w_T = h_6 - h_7 = C_P(T_6 - T_7) = \eta_{Ts}\ w_{Ts} = 0.86 \times 905.8 = 779.0$ kJ/kg

$T_7 = T_6 - w_T/C_P = 1500 - 779/1.004 = 723.7$ K

$$s_6 - s_7 = C_P \ln \frac{T_6}{T_7} - R \ln \frac{P_6}{P_7} = -0.1925 \text{ kJ/kg K}$$

$\psi_6 - \psi_7 = (h_6 - h_7) - T_o(s_6 - s_7) = 779.0 - 298.15(-0.1925) = 836.8$ kJ/kg

$$\eta_{2nd\ Law} = \frac{w_T}{\psi_6 - \psi_7} = 779.0 / 836.8 = \mathbf{0.931}$$

d) $\eta_{th} = q_H / w_{net}$; $w_{net} = w_T + w_{c1} + w_{c2} = 328.3$ kJ/kg

1st Law Combustor: $q + h_i = h_e + w$; $w = 0$

$q_c = h_6 - h_5 = C_P(T_6 - T_5)$

Regenerator: $\eta_{reg} = \dfrac{T_5 - T_4}{T_7 - T_4} = 0.8$ -> $T_5 = 692.1$ K

$q_H = q_c = 810.7$ kJ/kg; $\eta_{th} =$ **0.405**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.136

Repeat the questions in Problem 10.36 when we assume that friction causes pressure drops in the burner and on both sides of the regenerator. In each case, the pressure drop is estimated to be 2% of the inlet pressure to that component of the system, so P_3 = 588 kPa, P_4 = 0.98 P_3 and P_6 = 102 kPa.

Solution:

From solution Problem 10.36: $T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 300\ \text{K}\ (6)^{0.286} = 500.8\ \text{K}$

$w_C = -w_{12} = C_{P0}(T_2 - T_1) = 1.004\ \text{kJ/kg-K}\ (500.8 - 300)\ \text{K} = 201.6\ \text{kJ/kg}$

$P_3 = 0.98 \times 600 = 588\ \text{kPa}, \quad P_4 = 0.98 \times 588 = 576.2\ \text{kPa}$

$s_5 = s_4 \Rightarrow \quad P_5 = P_4(T_{5S}/T_4)^{\frac{k}{k-1}} = 576.2\ \text{kPa}\ \left(\frac{1399.2}{1600}\right)^{3.5} =$ **360.4 kPa**

$P_6 = 100/0.98 = 102\ \text{kPa}, \quad s_{6S} = s_5$

$T_6 = T_5\left(\frac{P_6}{P_5}\right)^{\frac{k-1}{k}} = 1399.2\left(\frac{102}{292.8}\right)^{0.286} = 975.2\ \text{K}$

$w_{ST2} = C_{P0}(T_5 - T_6) = 1.004(1399.2 - 975.2) = 425.7\ \text{kJ/kg}$

$\dot{m} = \dot{W}_{NET}/w_{NET} = 150\ \text{kW}\ /425.7\ \text{kJ/kg} =$ **0.352 kg/s**

$T_3 = T_6 = 975.2\ \text{K}$

$q_H = C_{P0}(T_4 - T_3) = 1.004\ (1600 - 975.2) = 627.3\ \text{kJ/kg}$

$\eta_{TH} = w_{NET}/q_H = 425.7/627.3 =$ **0.678**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.137

A gasoline engine has a volumetric compression ratio of 9. The state before compression is 290 K, 90 kPa, and the peak cycle temperature is 1800 K. Find the pressure after expansion, the cycle net work and the cycle efficiency using properties from Table A.7.

Use table A.7.1 and interpolation.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.19

$$0 = s^o_{T2} - s^o_{T1} - R \ln(P_2/P_1) = s^o_{T2} - s^o_{T1} - R \ln(T_2 v_1/T_1 v_2)$$

$$s^o_{T2} - R \ln(T_2/T_1) = s^o_{T1} + R \ln(v_1/v_2) = 6.83521 + 0.287 \ln 9 = 7.4658$$

This becomes trial and error so estimate first at 680 K and use A.7.1.

$LHS_{680} = 7.7090 - 0.287 \ln(680/290) = 7.4644$ (too low)

$LHS_{700} = 7.7401 - 0.287 \ln(700/290) = 7.4872$ (too high)

Interpolate to get: $T_2 = 681.23$ K, $u_2 = 497.9$ kJ/kg

$P_2 = P_1 (T_2/T_1) (v_1/v_2) = 90 (681.23 / 290) \times 9 = 1902.7$ kPa

${}_1w_2 = u_1 - u_2 = 207.2 - 497.9 = -290.7$ kJ/kg

Combustion 2 to 3: constant volume $v_3 = v_2$

$q_H = u_3 - u_2 = 1486.3 - 497.9 = 988.4$ kJ/kg

$P_3 = P_2(T_3/T_2) = 1902.7 (1800/681.2) = 5028$ kPa

Expansion 3 to 4: $s_4 = s_3 \Rightarrow$ From Eq.6.19 as before

$$s^o_{T4} - R \ln(T_4/T_3) = s^o_{T3} + R \ln(v_3/v_4) = 8.8352 + 0.287 \ln(1/9) = 8.2046$$

This becomes trial and error so estimate first at 850 K and use A.7.1.

$LHS_{850} = 7.7090 - 0.287 \ln(850/1800) = 8.1674$ (too low)

$LHS_{900} = 7.7401 - 0.287 \ln(900/1800) = 8.2147$ (too high)

Interpolation $\Rightarrow$ $T_4 = 889.3$ K, $u_4 = 666$ kJ/kg

$P_4 = P_3(T_4/T_3)(v_3/v_4) = 5028 (889.3/1800) (1/9) =$ **276 kPa**

${}_3w_4 = u_3 - u_4 = 1486.3 - 666.0 = 820.3$ kJ/kg

Net work and overall efficiency

$w_{NET} = {}_3w_4 + {}_1w_2 = 820.3 - 290.7 =$ **529.6 kJ/kg**

$\eta = w_{NET}/q_H = 529.6/988.4 =$ **0.536**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.138

Consider an ideal air-standard diesel cycle in which the state before the compression process is 95 kPa, 290 K, and the compression ratio is 20. Find the maximum temperature (by iteration) in the cycle to have a thermal efficiency of 60%?

Solution:

Diesel cycle: $P_1 = 95$ kPa, $T_1 = 290$ K, $v_1/v_2 = 20$, $\eta_{TH} = 0.6$

Since the efficiency depends on T_3 and T_4, which are connected through the expansion process in a nonlinear manner we have an iterative problem.

$$T_2 = T_1(v_1/v_2)^{k-1} = 290 \text{ K } (20)^{0.4} = 961.2 \text{ K}$$

$$v_1 = 0.287 \text{ kJ/kg-K} \times 290 \text{ K}/95 \text{ kPa} = 0.876 \text{ m}^3/\text{kg} = v_4,$$

$$v_2 = v_1/CR = 0.876 / 20 = 0.0438 \text{ m}^3/\text{kg}$$

$$v_3 = v_2(T_3/T_2) = 0.0438 \text{ m}^3/\text{kg } (T_3/961.2) = 0.0000456\, T_3$$

$$T_3 = T_4\,(v_4/v_3)^{k-1} = \left(\frac{0.876}{0.0000456\, T_3}\right)^{0.4} \quad \Rightarrow \quad T_4 = 0.019345\, T_3^{1.4}$$

Now substitute this into the formula for the efficiency

$$\eta_{TH} = 0.60 = 1 - \frac{T_4 - T_1}{k(T_3 - T_2)} = 1 - \frac{0.019345 \times T_3^{1.4} - 290}{1.4(T_3 - 961.2)}$$

$$\Rightarrow \; 0.019345 \times T_3^{1.4} - 0.56 \times T_3 + 248.272 = 0$$

Trial and error on this non-linear equation in T_3

3050 K: LHS = +1.06 3040 K: LHS = -0.036,

Linear interpolation $T_3 =$ **3040 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.139

Find the temperature after combustion and the specific energy release by combustion in Problem 10.98 using cold air properties. This is a difficult problem and it requires iterations.

The worlds largest diesel engine has displacement of 25 m^3 running at 200 RPM in a two stroke cycle producing 100 000 hp. Assume an inlet state of 200 kPa, 300 K and a compression ratio of 20:1. What is the mean effective pressure?

We have 3 parameters for the cycle: T_1, P_1 and CR we need one more, so this comes from the total rate of work Eq.10.11.

$$\dot{W} = m\, P_{meff}\,(v_1 - v_2) \times N_{cyl} \times RPM/60 = P_{meff}\, V_{displ}\, RPM/60$$

$$P_{meff} = \dot{W}\, 60 / V_{displ}\, RPM = \frac{100\,000 \times 0.746\ kW \times 60\ s}{25\ m^3 \times 200} = 895\ kPa$$

$$v_1 = RT/P = 0.287\ kJ/kg\text{-}K \times 300\ K / 200\ kPa = 0.4305\ m^3/kg;$$

$$w_{net} = P_{meff}\,(v_1 - v_2) = 895 \times 0.4305\,(1 - \frac{1}{20}) = 366.03\ kJ/kg$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 300\ K\ (20)^{0.4} = 994.3\ K$$

Combustion and expansion volumes

$$v_3 = v_2 \times T_3/T_2 = v_1\, T_3/(T_2 \times CR)\ ; \quad v_4 = v_1$$

Expansion process, isentropic from Eq.6.23

$$T_4 = T_3\,(v_3/v_4)^{k-1} = T_3\,[T_3/\,(CR \times T_2)]^{k-1} = T_3^k\,(CR \times T_2)^{1-k} = 0.01908\ T_3^k$$

The net work is also given by the heat transfers

$$w_{net} = q_H - q_L = C_P(T_3 - T_2) - C_v(T_4 - T_1)$$

Substitute w_{net} and T_4 into this equation and we get

$$366.03 = 1.004(T_3 - 994.3) - 0.717(0.01908\ T_3^k - 300)$$

divide by 1.004 and combine terms to get

$$1144.63 = T_3 - 0.013626\ T_3^k$$

Trial and error, guess T_3 ⇨ $RHS_{1400} = 1054.1$; $RHS_{1600} = 1183$

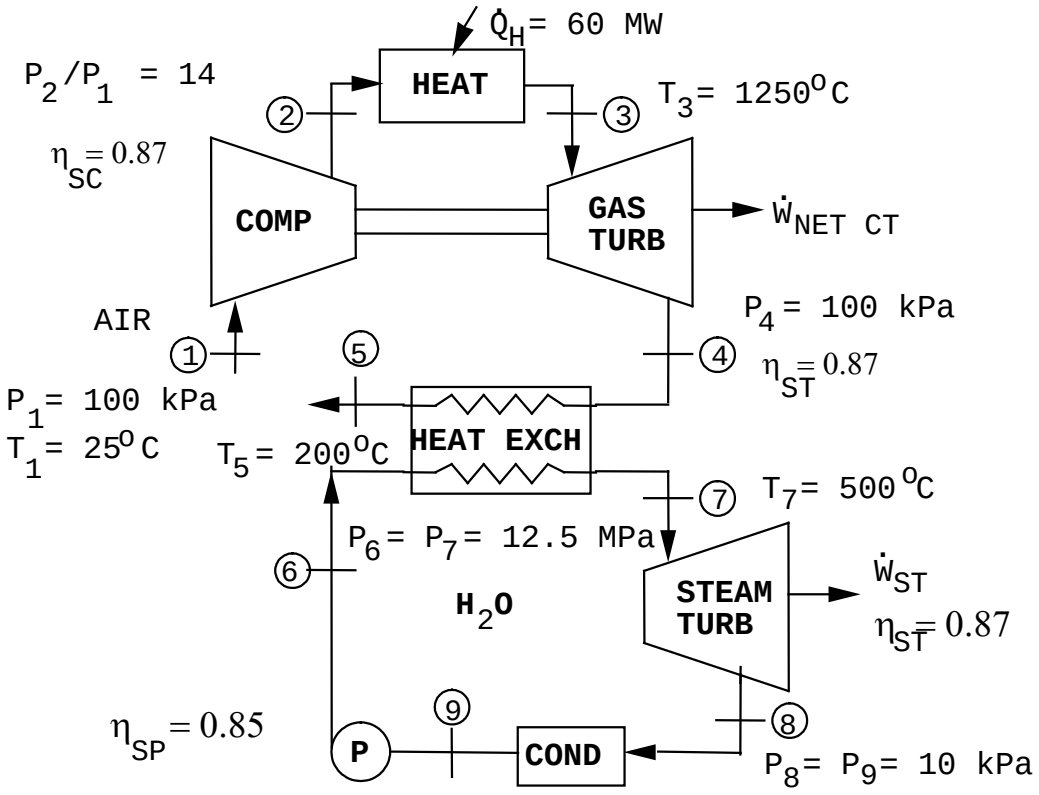
Interpolate: T_3 = **1540.5 K**

$$q_H = C_P(T_3 - T_2) = 1.004(1540.5 - 994.3) = \mathbf{548\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.140

Reevaluate the combined Brayton and Rankine cycles in Problem 10.121. For a more realistic case assume the air compressor, the air turbine, the steam turbine and the pump all have an isentropic efficiency of 87%.



a) From Air Tables, A.7: $P_{r1} = 1.0913$, $h_1 = 298.66$, $h_5 = 475.84$ kJ/kg

$$s_2 = s_1 \Rightarrow P_{r2S} = P_{r1}(P_2/P_1) = 1.0913 \times 14 = 15.2782$$

$$T_{2S} = 629\ \text{K}, \quad h_{2S} = 634.48$$

$$w_{SC} = h_1 - h_{2S} = 298.66 - 634.48 = -335.82\ \text{kJ/kg}$$

$$w_C = w_{SC}/\eta_{SC} = -335.82/0.87 = -386 = h_1 - h_2 \Rightarrow h_2 = 684.66\ \text{kJ/kg}$$

At $T_3 = 1523.2$ K: $P_{r3} = 515.493$, $h_3 = 1663.91$ kJ/kg

$$\dot{m}_{AIR} = \dot{Q}_H/(h_3 - h_2) = \frac{60\,000}{1663.91 - 684.66} = \mathbf{61.27\ kg/s}$$

b) $$P_{r4S} = P_{r3}(P_4/P_3) = 515.493(1/14) = 36.8209$$

$$\Rightarrow T_{4S} = 791\ \text{K}, \quad h_{4S} = 812.68\ \text{kJ/kg}$$

$$w_{ST} = h_3 - h_{4S} = 1663.91 - 812.68 = 851.23\ \text{kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$w_T = \eta_{ST} \times w_{ST} = 0.87 \times 851.23 = 740.57 = h_3 - h_4 \quad => \quad h_4 = 923.34 \text{ kJ/kg}$$

Steam cycle: $-w_{SP} \approx 0.00101(12500 - 10) = 12.615$ kJ/kg

$$-w_P = -\, w_{SP}/\eta_{SP} = 12.615/0.85 = 14.84 \text{ kJ/kg}$$

$$h_6 = h_9 - w_P = 191.83 + 14.84 = 206.67 \text{ kJ/kg}$$

At 12.5 MPa, 500 ^{o}C: $h_7 = 3341.7$ kJ/kg, $s_7 = 6.4617$ kJ/kg K

$$\dot{m}_{H_2O} = \dot{m}_{AIR} \frac{h_4 - h_5}{h_7 - h_6} = 61.27 \frac{923.34 - 475.84}{3341.7 - 206.67} = \mathbf{8.746 \text{ kg/s}}$$

c) $s_{8S} = s_7 = 6.4617 = 0.6492 + x_{8S} \times 7.501, \quad x_{8S} = 0.7749$

$$h_{8S} = 191.81 + 0.7749 \times 2392.8 = 2046.0 \text{ kJ/kg}$$

$$w_{ST} = h_7 - h_{8S} = 3341.7 - 2046.0 = 1295.7 \text{ kJ/kg}$$

$$w_T = \eta_{ST} \times w_{ST} = 0.87 \times 1295.7 = 1127.3 \text{ kJ/kg}$$

$$\dot{W}_{NET} = \left[\dot{m}(w_T + w_C)\right]_{AIR} + \left[\dot{m}(w_T + w_P)\right]_{H_2O}$$

$$= 61.27(740.57 - 386.0) + 8.746(1127.3 - 14.84)$$

$$= 21725 + 9730 = 31455 \text{ kW} = 31.455 \text{ MW}$$

$$\eta_{TH} = \dot{W}_{NET}/\dot{Q}_H = 31.455/60 = \mathbf{0.524}$$

Problems solved using Table A.7.2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.37

Repeat Problem 10.35 when the intercooler brings the air to T_3 = 320 K. The corrected formula for the optimal pressure is $P_2 = [\, P_1 P_4 \, (T_3/T_1)^{n/(n-1)}]^{1/2}$ see Problem 7.245, where *n* is the exponent in the assumed polytropic process.

Solution:

The polytropic process has n = k (isentropic) so $n/(n - 1) = 1.4/0.4 = 3.5$

$$P_2 = 400 \text{ kPa} \sqrt{(320/290)^{3.5}} = 475.2 \text{ kPa}$$

C.V. C1: $s_2 = s_1 \Rightarrow P_{r2} = P_{r1}(P_2/P_1) = 0.9899 \times (475.2/100)$

$$= 4.704 \Rightarrow T_2 = 452 \text{ K}, \; h_2 = 453.75$$

$$-w_{C1} = h_2 - h_1 = 453.75 - 290.43 = \mathbf{163.3 \text{ kJ/kg}}$$

C.V. Cooler: $q_{OUT} = h_2 - h_3 = 453.75 - 320.576 = \mathbf{133.2 \text{ kJ/kg}}$

C.V. C2: $s_4 = s_3 \Rightarrow P_{r4} = P_{r3}(P_4/P_3) = 1.3972 \times (1600/475.2) = 4.704$

$$\Rightarrow \quad T_4 = T_2 = 452 \text{ K}, \quad h_4 = 453.75$$

$$-w_{C2} = h_4 - h_3 = 453.75 - 320.576 = \mathbf{133.2 \text{ kJ/kg}}$$

10.42

A gas turbine with air as the working fluid has two ideal turbine sections, as shown in Fig. P10.42, the first of which drives the ideal compressor, with the second producing the power output. The compressor input is at 290 K, 100 kPa, and the exit is at 450 kPa. A fraction of flow, *x*, bypasses the burner and the rest (1 – *x*) goes through the burner where 1200 kJ/kg is added by combustion. The two flows then mix before entering the first turbine and continue through the second turbine, with exhaust at 100 kPa. If the mixing should result in a temperature of 1000 K into the first turbine find the fraction *x*. Find the required pressure and temperature into the second turbine and its specific power output.

C.V.Comp.: $-w_C = h_2 - h_1$; $s_2 = s_1$

$P_{r2} = P_{r1}\,(P_2/P_1) = 0.9899 \times (450/100) = 4.4545$,

A.7.2 interpolate: $T_2 = 445$ K, $h_2 = 446.74$ kJ/kg,

$-w_C = 446.74 - 290.43 = 156.3$ kJ/kg

C.V.Burner: $h_3 = h_2 + q_H = 446.74 + 1200 = 1646.74$ kJ/kg

$\Rightarrow T_3 = 1509$ K

C.V.Mixing chamber: $(1 - x)h_3 + xh_2 = h_{MIX} = 1046.22$ kJ/kg

$$x = \frac{h_3 - h_{MIX}}{h_3 - h_2} = \frac{1646.74 - 1046.22}{1646.74 - 446.74} = \mathbf{0.50}$$

$\dot{W}_{T1} = \dot{W}_{C,in} \Rightarrow \dot{w}_{T1} = -w_C = 156.3$ kJ/kg $= h_3 - h_4$

$h_4 = 1046.22 - 156.3 = 889.9$ kJ/kg $\Rightarrow T_4 =$ **861 K**

$P_4 = (P_{r4}/P_{rMIX})\,P_{MIX} = (51/91.65) \times 450 =$ **250.4 kPa**

$s_4 = s_5 \Rightarrow P_{r5} = P_{r4}\,(P_5/P_4) = 51 \times (100/250.4) = 20.367$

A.7.2 interpolate: $h_5 = 688.2$ kJ/kg, $T_5 = 676$ K

$w_{T2} = h_4 - h_5 = 889.9 - 688.2 =$ **201.7 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.80

Repeat Problem 10.73, but assume variable specific heat. The ideal gas air tables, Table A.7, are recommended for this calculation (and the specific heat from Fig. 3.26 at high temperature).

Solution:

Table A.7 is used with interpolation.

$T_1 = 283.2$ K, $u_1 = 202.3$ kJ/kg, $v_{r1} = 210.44$

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From definition of the v_r function

$v_{r2} = v_{r1} (v_2/v_1) = 210.4\ (1/7) = 30.063$

Interpolate to get: $T_2 = 603.9$ K, $u_2 = 438.1$ kJ/kg

$\Rightarrow\ -{}_1w_2 = u_2 - u_1 = 235.8$ kJ/kg,

$u_3 = 438.1 + 1800 = 2238.1 \Rightarrow T_3 =$ **2573.4 K**, $v_{r3} = 0.34118$

$P_3 = 90 \times 7 \times 2573.4 / 283.2 =$ **5725 kPa**

Expansion 3 to 4: $s_4 = s_3 \Rightarrow$ From the v_r function as before

$v_{r4} = v_{r3} (v_4/v_3) = 0.34118\ (7) = 2.3883$

Interpolation $\Rightarrow T_4 = 1435.4$ K, $u_4 = 1145.8$ kJ/kg

${}_3w_4 = u_3 - u_4 = 2238.1 - 1145.8 = 1092.3$ kJ/kg

Net work, efficiency and mep

➔ $w_{net} = {}_3w_4 + {}_1w_2 = 1092.3 - 235.8 = 856.5$ kJ/kg

$\eta_{TH} = w_{net} / q_H = 856.5 / 1800 =$ **0.476**

$v_1 = RT_1/P_1 = (0.287 \times 283.2)/90 = 0.9029$ m^3/kg

$v_2 = (1/7)\, v_1 = 0.1290$ m^3/kg

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = 856.5 / (0.9029 - 0.129) =$$ **1107 kPa**

Brayton Cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.141E

In a Brayton cycle the inlet is at 540 R, 14 psia and the combustion adds 350 Btu/lbm. The maximum temperature is 2500 R due to material considerations. Find the maximum permissible compression ratio and for that the cycle efficiency using cold air properties.

Solution:

Combustion: $h_3 = h_2 + q_H$; $\quad {}_2w_3 = 0$ and $T_{max} = T_3 = 2500$ R

$$T_2 = T_3 - q_H/C_P = 2500 - 350/0.24 = 1041.67 \text{ R}$$

Reversible adiabatic compression leads to constant s, from Eq.6.23:

$$P_2 / P_1 = (T_2/T_1)^{\frac{k}{k-1}} = (1041.67/540)^{3.5} = \mathbf{9.9696}$$

We can find the efficiency from the compression ratio, Eq.10.1

$$\eta = 1 - T_1/T_2 = 1 - 540/1041.67 = \mathbf{0.482}$$

We can also compute all process work terms.

Reversible adiabatic expansion leads to constant s, from Eq.6.23

$$T_4 = T_3 (P_4/P_3)^{\frac{k-1}{k}} = T_3\, T_1/T_2 = 2500 \text{ R} \frac{540}{1041.67} = 1296 \text{ R}$$

For net work we get

$$w_T = C_P (T_3 - T_4) = 0.24 (2500 - 1296) = 288.96 \text{ Btu/lbm}$$

$$w_C = C_P (T_2 - T_1) = 0.24 (1041.67 - 540) = 120.4 \text{ Btu/lbm}$$

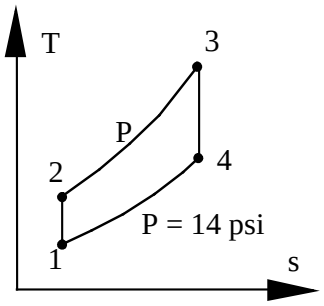
$$w_{net} = w_T - w_C = 288.96 - 120.4 = 168.56 \text{ Btu/lbm}$$

$$\eta = w_{net} / q_H = 168.56 / 350 = 0.482$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.142E

A Brayton cycle has compression ratio of 15:1 with a high temperature of 2900 R and the inlet at 520 R, 14 psia. Use cold air properties and find the specific heat transfer input and the specific net work output.



Brayton cycle so this means:

Minimum T: $T_1 = 520$ R

Maximum T: $T_3 = 2900$ R

Pressure ratio: $P_2/P_1 = 15$

Compression in compressor: $s_2 = s_1$

$\Rightarrow$ Implemented in Eq.6.23

$$T_2 = T_1 (P_2/P_1)^{\frac{k-1}{k}} = 520\ (15)^{0.286} = 1128.1 \text{ R}$$

Energy input is from the combustor

$$q_H = C_{P0}(T_3 - T_2) = 0.24\ (2900 - 1128.1) = \mathbf{425.3\ Btu/lbm}$$

Do the overall cycle efficiency and the net work

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 15^{-0.4/1.4} = 0.5387$$

$$w_{NET} = \eta\ q_H = 0.5387 \times 425.3 = \mathbf{229.1\ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.143E

A large stationary Brayton cycle gas-turbine power plant delivers a power output of 100 000 hp to an electric generator. The minimum temperature in the cycle is 540 R, and the exhaust temperature is 1350 R. The minimum pressure in the cycle is 1 atm, and the compressor pressure ratio is 14 to 1. Calculate the power output of the turbine, the fraction of the turbine output required to drive the compressor and the thermal efficiency of the cycle?

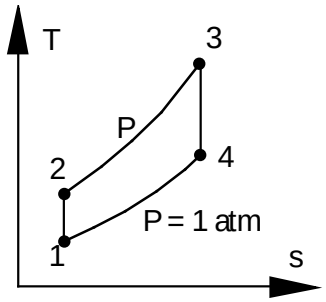
Brayton:

$\dot{w}_{NET}$ = 100 000 hp

P_1 = 1 atm, T_1 = 540 R

P_2/P_1 = 14, T_3 = 2900 R

Solve using constant C_{P0}:



Compression in compressor: $s_2 = s_1 \Rightarrow$ Implemented in Eq.6.23

$$\rightarrow T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 540(14)^{0.2857} = 1148.6 \text{ R}$$

$$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 0.24\ (1148.6 - 540) = 146.1 \text{ Btu/lbm}$$

Expansion in turbine: $s_4 = s_3 \Rightarrow$ Implemented in Eq.6.23

$$T_3 = T_4\left(\frac{P_3}{P_4}\right)^{\frac{k-1}{k}} = 1350\ (14)^{0.2857} = 2869.3 \text{ R}$$

$$w_T = h_3 - h_4 = C_{P0}(T_3 - T_4) = 0.24(2869.3 - 1350) = 364.6 \text{ Btu/lbm}$$

$$w_{NET} = w_T - w_C = 364.6 - 146.1 = 218.5 \text{ Btu/lbm}$$

$$\dot{m} = \dot{W}_{NET}/w_{NET} = 100\ 000 \times 2544/218.5 = 1\ 164\ 302 \text{ lbm/h}$$

$$\dot{W}_T = \dot{m}w_T = \mathbf{166\ 865\ hp}, \qquad w_C/w_T = \mathbf{0.40}$$

Energy input is from the combustor

$$q_H = C_{P0}(T_3 - T_2) = 0.24(2869.3 - 1148.6) = 413 \text{ Btu/lbm}$$

$$\eta_{TH} = w_{NET}/q_H = 218.5/413 = \mathbf{0.529}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.144E

A Brayton cycle produces 14 000 Btu/s with an inlet state of 60 F, 14.7 psia, and a compression ratio of 16:1. The heat added in the combustion is 480 Btu/lbm. What are the highest temperature and the mass flow rate of air, assuming cold air properties?

Solution:

Efficiency is from Eq.10.1

$$\eta = \frac{\dot{W}_{net}}{\dot{Q}_H} = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 16^{-0.4/1.4} = 0.547$$

from the required power we can find the needed heat transfer

$$\dot{Q}_H = \dot{W}_{net} / \eta = \frac{14\ 000}{0.547} = 25\ 594 \text{ Btu/s}$$

$$\dot{m} = \dot{Q}_H / q_H = \frac{25\ 594 \text{ Btu/s}}{480 \text{ Btu/lbm}} = \mathbf{53.32\ lbm/s}$$

Temperature after compression is (Eq.6.23)

$$T_2 = T_1 r_p^{(k-1)/k} = 519.7 \times 16^{0.4/1.4} = 1148 \text{ R}$$

The highest temperature is after combustion

$$T_3 = T_2 + q_H/C_p = 1148 + \frac{480}{0.24} = \mathbf{3148\ R}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.145E

Do the previous problem with properties from table F.5 instead of cold air properties.

Solution:

With the variable specific heat we must go through the processes one by one to get net work and the highest temperature T_3.

From F.5: $h_1 = 124.38$ btu/lbm, $s^o_{T1} = 1.63074$ Btu/lbm R

The compression is reversible and adiabatic so constant s. From Eq.6.19

$$s_2 = s_1 \Rightarrow s^o_{T2} = s^o_{T1} + R \ln\left(\frac{P_2}{P_1}\right) = 1.63074 + \frac{53.34}{778} \ln 16$$

$$= 1.82083 \text{ Btu/lbm R}$$

back interpolate in F.5 $\Rightarrow$ $T_2 = 1133.5$ R, $h_2 = 274.58$ Btu/lbm

Energy equation with compressor work in

$$w_C = -{}_1w_2 = h_2 - h_1 = 274.58 - 124.383 = 150.2 \text{ Btu/lbm}$$

Energy Eq. combustor: $h_3 = h_2 + q_H = 274.58 + 480 = 754.58$ Btu/lbm

State 3: (P, h): $\mathbf{T_3 = 2876.7\ R}$, $s^o_{T3} = 2.07443$ Btu/lbm R

The expansion is reversible and adiabatic so constant s. From Eq.6.19

$$s_4 = s_3 \Rightarrow s^o_{T4} = s^o_{T3} + R\ln(P_4/P_3) = 2.07443 + \frac{53.34}{778} \ln(1/16) = 1.88434$$

$\Rightarrow$ $T_4 = 1450.6$ R, $h_4 = 356.27$ Btu/lbm

Energy equation with turbine work out

$$w_T = h_3 - h_4 = 754.58 - 356.27 = 398.31 \text{ Btu/lbm}$$

Now the net work is

$$w_{net} = w_T - w_C = 398.31 - 150.2 = 248.11 \text{ Btu/lbm}$$

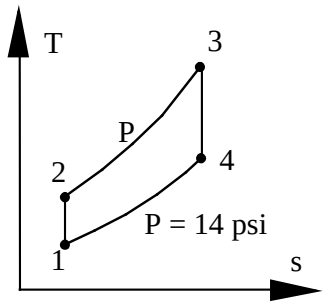
The total required power requires a mass flow rate as

$$\dot{m} = \frac{\dot{W}_{net}}{w_{net}} = \frac{14\,000}{248.11} \frac{\text{Btu/s}}{\text{Btu/lbm}} = \mathbf{56.4\ lbm/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.146E

Solve Problem 10.142E using the air tables F.5 instead of cold air properties.



Brayton cycle so this means:

Minimum T: $T_1 = 520$ R

Maximum T: $T_3 = 2900$ R

Pressure ratio: $P_2/P_1 = 15$

Compression in compressor: $s_2 = s_1$

$\Rightarrow$ Implemented in Eq.6.19

$$s_2 = s_1 \Rightarrow s^o_{T2} = s^o_{T1} + R\ln(P_2/P_1) = 1.6307 + \frac{53.34}{778}\ln 15 = 1.8164$$

$$\Rightarrow T_2 = 1113.8 \text{ R}, \quad h_2 = 269.6 \text{ Btu/lbm}$$

$$w_C = h_2 - h_1 = 269.6 - 124.4 = 145.2 \text{ Btu/lbm}$$

Energy input is from the combustor

$$q_H = h_3 - h_2 = 761.4 - 269.6 = \mathbf{491.8\ Btu/lbm}$$

The expansion is reversible and adiabatic so constant s. From Eq.6.19

$$s_4 = s_3 \Rightarrow s^o_{T4} = s^o_{T3} + R\ln(P_4/P_3) = 2.0768 + \frac{53.34}{778}\ln(1/15) = 1.8911$$

$$\Rightarrow T_4 = 1488.5 \text{ R}, \quad h_4 = 366.2 \text{ Btu/lbm}$$

Energy equation with turbine work out

$$w_T = h_3 - h_4 = 761.3 - 366.2 = 395.1 \text{ Btu/lbm}$$

Now the net work is

$$w_{net} = w_T - w_C = 395.1 - 145.2 = \mathbf{249.9\ Btu/lbm}$$

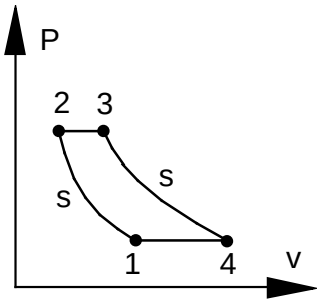
[Comment: Cycle efficiency $\eta = \dfrac{\dot{W}_{net}}{\dot{Q}_H} = \dfrac{w_{net}}{q_H} = \dfrac{249.9}{491.8} = 0.508$]

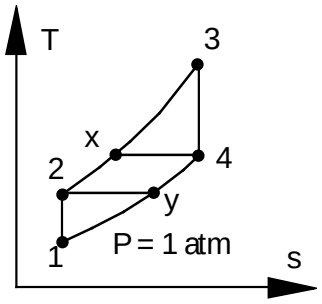
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.147E

An ideal regenerator is incorporated into the ideal air-standard Brayton cycle of Problem 10.143E. Calculate the cycle thermal efficiency with this modification.

Solution:





Compression ratio

$$\frac{P_2}{P_1} = 14$$

Exhaust temperature

$T_4 = 1350$ R

Solving for the cycle work terms and heat transfer from problem 10.143E:

The compression is reversible and adiabatic so constant s. From Eq.6.23

$$\rightarrow T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 540\ (14)^{\,0.2857} = 1148.6 \text{ R}$$

$$w_C = h_2 - h_1 = C_{P0}(T_2 - T_1) = 0.24\ (1148.6 - 540) = 146.1 \text{ Btu/lbm}$$

Expansion in turbine: $s_4 = s_3 \Rightarrow$ Implemented in Eq.6.23

$$T_3 = T_4\left(\frac{P_3}{P_4}\right)^{\frac{k-1}{k}} = 1350\ (14)^{0.2857} = 2869.3 \text{ R}$$

$$w_T = h_3 - h_4 = C_{P0}(T_3 - T_4) = 0.24(2869.3 - 1350) = 364.6 \text{ Btu/lbm}$$

$$w_{NET} = w_T - w_C = 364.6 - 146.1 = 218.5 \text{ Btu/lbm}$$

Ideal regenerator: $T_X = T_4 = 1350$ R

$$q_H = h_3 - h_X = 0.24(2869.3 - 1350) = 364.6 \text{ Btu/lbm} = w_T$$

$$\eta_{TH} = w_{NET}/q_H = 218.5/364.6 = \mathbf{0.60}$$

The short answer from the efficiency of an ideal regenerator ($T_4 = T_x$) from p.471

$$\eta_{TH} = 1 - \frac{T_1}{T_3}\left(\frac{P_2}{P_1}\right)^{\frac{k-1}{k}} = 1 - \frac{T_2}{T_3} = 1 - \frac{1148.6}{2869.3} = \mathbf{0.60}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.148E

An air-standard Ericsson cycle has an ideal regenerator as shown in Fig. P10.44. Heat is supplied at 1800 F and heat is rejected at 150 F. Pressure at the beginning of the isothermal compression process is 10 lbf/in.^{2}. The heat added is 300 Btu/lbm. Find the compressor work, the turbine work, and the cycle efficiency.

Identify the states

Heat supplied at high temperature $T_4 = T_3 = 1800$ F = 2349.7 R

Heat rejected at low temperature $T_1 = T_2 = 150$ F = 609.7 R

Beginning of the compression: $P_1 = 10$ lbf/in^2

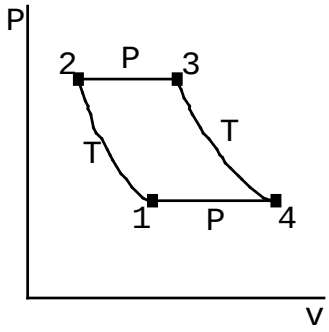
Ideal regenerator: ${}_2q_3 = -{}_4q_1 \Rightarrow q_H = {}_3q_4 \Rightarrow$

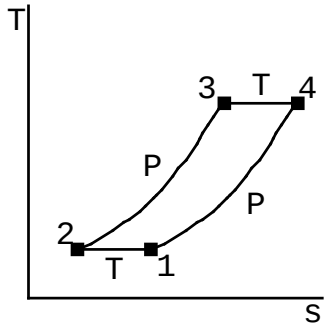
$$w_T = q_H = \mathbf{300\ Btu/lbm}$$

$\eta_{TH} = \eta_{CARNOT\ TH.} = 1 - T_L/T_H = 1 - 609.7/2349.7 = \mathbf{0.7405}$

$w_{net} = \eta_{TH}\, q_H = 0.7405 \times 300$ Btu/lbm = 222 Btu/lbm

$q_L = -w_C = 300 - 222 = \mathbf{78\ Btu/lbm}$





Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.149E

The turbine in a jet engine receives air at 2200 R, 220 lbf/in.^{2}. It exhausts to a nozzle at 35 lbf/in.^{2}, which in turn exhausts to the atmosphere at 14.7 lbf/in.^{2}. Find the nozzle inlet temperature and the nozzle exit velocity. Assume negligible kinetic energy out of the turbine and reversible processes.

Solution:

C.V. Turbine: $h_i = 560.588$ Btu/lbm, $s^o_{Ti} = 1.99765$ Btu/lbm R, $s_{es} = s_i$

Then from Eq.6.19

$$\Rightarrow s^o_{Tes} = s^o_{Ti} + R \ln(P_e/P_i) = 1.99765 + \frac{53.34}{778} \ln (35/220) = 1.8716 \frac{\text{Btu}}{\text{lbm R}}$$

Table F.5 $T_{es} = 1382$ R, $h_{es} = 338.27$ Btu/lbm,

Energy eq.: $w_{T,s} = h_i - h_{es} = 560.588 - 338.27 = 222.3$ Btu/lbm

C.V. Nozzle: $h_i = 338.27$ Btu/lbm, $s^o_{Ti} = 1.8716$ Btu/lbm R, $s_{es} = s_i$

Then from Eq.6.19

$$\Rightarrow \quad s^o_{Tes} = s^o_{Ti} + R \ln(P_e/P_i) = 1.8716 + \frac{53.34}{778} \ln \left(\frac{14.7}{35}\right) = 1.81212 \frac{\text{Btu}}{\text{lbm R}}$$

Table F.5 $\Rightarrow$ $T_{e,s} = 1095.0$ R, $h_{e,s} = 264.9$ Btu/lbm

Energy Eq.: $(1/2)\mathbf{V}^2_{e,s} = h_i - h_{e,s} = 338.27 - 264.9 = 73.37$ Btu/lbm

$$\mathbf{V}_{e,AC} = \sqrt{2 \times 25037 \times 73.37} = \mathbf{1917\ ft/s}$$

Recall 1 Btu/lbm = 25 037 ft^2/s^2

10.150E

An air standard refrigeration cycle has air into the compressor at 14 psia, 500 R with a compression ratio of 3:1. The temperature after heat rejection is 540 R. Find the COP and the highest cycle temperature.

From the isentropic compression/expansion processes, Eq.6.23

$$T_2 / T_1 = (P_2/P_1)^{\frac{k-1}{k}} = 3^{0.2857} = 1.36874 = T_3/T_4$$

$$T_2 = 1.36874 \ T_1 = \mathbf{684.4\ R}$$

The COP, Eq.10.5, is

$$\beta = \frac{1}{\frac{T_2}{T_1} - 1} = [\ 1.36874 - 1]^{-1} = \mathbf{2.712}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.151E

A 4 stroke gasoline engine runs at 1800 RPM with a total displacement of 150 in.^{3} and a compression ratio of 10:1. The intake is at 520 R, 10 psia with a mean effective pressure of 90 psia. Find the cycle efficiency and power output.

Efficiency from the compression ratio

$$\eta = 1 - CR^{1-k} = 1 - 10^{-0.4} = \mathbf{0.60}$$

The power output comes from speed and displacement in Eq. 10.11

$$\dot{W} = P_{meff} V_{displ} \frac{RPM}{60} \frac{1}{2} = 90 \frac{lbf}{in^2} \times 150 \text{ in.}^3 \times \frac{1800}{60} (1/s) \times \frac{1}{2}$$

$$= \mathbf{16\ 875\ lbf\text{-}ft/s = 30.7\ hp = 21.7\ Btu/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.152E

Air flows into a gasoline engine at 14 lbf/in.^{2}, 540 R. The air is then compressed with a volumetric compression ratio of 10:1. In the combustion process 560 Btu/lbm of energy is released as the fuel burns. Find the temperature and pressure after combustion.

Solution:

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and 6.25

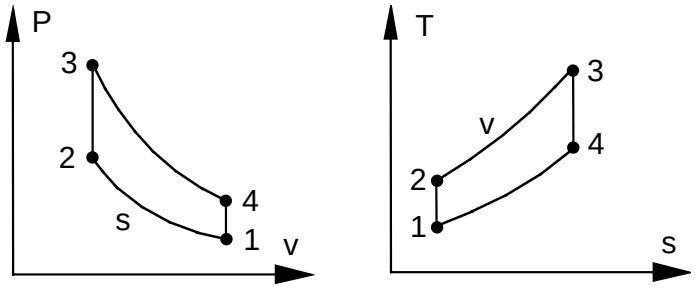
$T_2 = T_1 (v_1/v_2)^{k-1} = 540\ R \times 10^{0.4} = 1356.4\ R$

$P_2 = P_1 \times (v_1/v_2)^k = 14\ lbf/in^2 \times 10^{1.4} = 351.7\ lbf/in^2$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$T_3 = T_2 + q_H/C_v = 1356.4 + 560/0.171 =$ **4631 R**

$P_3 = P_2 \times (T_3/T_2) = 351.7\ lbf/in^2 \times (4631 / 1356.4) =$ **1201 lbf/in^2**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.153E

Find the missing pressures and temperatures in the previous cycle.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and 6.25

$T_2 = T_1 (v_1/v_2)^{k-1} = 540\ \text{R} \times 10^{0.4} =$ **1356.4 R**

$P_2 = P_1 \times (v_1/v_2)^{k} = 14\ \text{lbf/in}^2 \times 10^{1.4} =$ **351.7 lbf/in^2**

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$T_3 = T_2 + q_H/C_v = 1356.4 + 560/0.171 =$ **4631 R**

$P_3 = P_2 \times (T_3/T_2) = 351.7\ \text{lbf/in}^2 \times (4631 / 1356.4) =$ **1201 lbf/in^2**

$T_4 = T_3 / (v_1/v_2)^{k-1} = 4631\ \text{R} \times 10^{-0.4} =$ **1843.6 R**

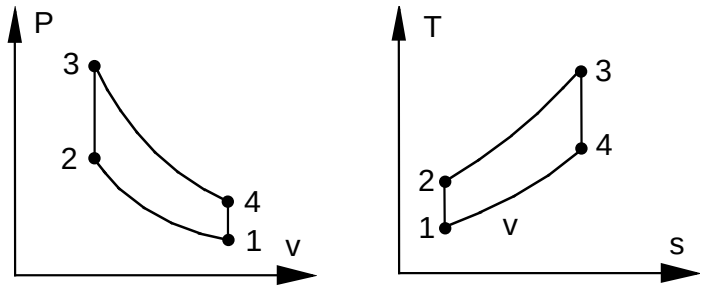
$P_4 = P_3 / (v_1/v_2)^{k} = 1201\ \text{psi} \times 10^{-1.4} =$ **47.8 lbf/in^2**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.154E

To approximate an actual spark-ignition engine consider an air-standard Otto cycle that has a heat addition of 800 Btu/lbm of air, a compression ratio of 7, and a pressure and temperature at the beginning of the compression process of 13 lbf/in.^{2}, 50 F. Assuming constant specific heat, with the value from Table F.4, determine the maximum pressure and temperature of the cycle, the thermal efficiency of the cycle and the mean effective pressure.

Solution:



State 1: $v_1 = RT_1/P_1 = \dfrac{53.34\times510}{13\times144} = 14.532$ ft^3/lbm, $v_2 = v_1/7 = 2.076$ ft^3/lbm

The compression process, reversible adiabatic so then isentropic. The constant s is implemented with Eq.6.25 and Eq.6.24

$$P_2 = P_1(v_1/v_2)^k = 13(7)^{1.4} = 198.2 \text{ lbf/in}^2$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 510(7)^{0.4} = 1110.7 \text{ R}$$

The combustion process with constant volume, $q_H = 800$ Btu/lbm

$$T_3 = T_2 + q_H/C_{V0} = 1110.7 + 800/0.171 = \mathbf{5789\ R}$$

$$P_3 = P_2T_3/T_2 = 198.2 \times 5789/1110.7 = \mathbf{1033\ lbf/in^2}$$

Cycle efficiency from the ideal cycle as in Eq.10.12

$$\eta_{TH} = 1 - (T_1/T_2) = 1 - 510/1110.7 = \mathbf{0.541}$$

To get the mean effective pressure we need the net work

$$w_{NET} = \eta_{TH} \times q_H = 0.541 \times 800 = 432.8 \text{ Btu/lbm}$$

$$P_{meff} = \frac{w_{NET}}{v_1\text{-}v_2} = \frac{432.8\times778}{(14.532\text{-}2.076)\times144} = \mathbf{188\ lbf/in^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.155E

A 4 stroke 85 in^3. gasoline engine runs at 2500 RPM has an efficiency of 60%. The state before compression is 6 psia, 500 R and after combustion it is at 4400 R. Find the highest T and P in the cycle, the specific heat transfer added, the cycle mep and the total power produced.

This is a basic 4-stroke Otto cycle.
Compression ratio from the efficiency

$$\eta = 1 - CR^{1-k} \quad => \quad CR = (1-\eta)^{-1/0.4} = 9.882$$

Compression: $T_2 = T_1(CR)^{k-1} = 500 \times (9.882)^{0.4} = 1250$ R

$$P_2 = P_1\, CR^k = 6 \times 9.882^{1.4} = 148.2 \text{ psia}$$

Combustion $v_3 = v_2$. Highest T and P are after combustion.

$$T_3 = \mathbf{4400\ R}, \quad P_3 = P_2\, T_3 / T_2 = \frac{148.2 \times 4400}{1250} = \mathbf{521.7\ psia}$$

$$q_H = u_3 - u_2 = C_v(T_3 - T_2) = 0.171\ (4400 - 1250) = \mathbf{538.65\ Btu/lbm}$$

$$w_{net} = \eta_{TH} \times q_H = 0.6 \times 538.65 = 323.19 \text{ Btu/lbm}$$

Displacement and P_{meff}

$$v_1 = RT_1/P_1 = 53.34 \text{ ft-lbf/lbm-R} \times 500 \text{ R}/(144 \times 6 \text{ psia}) = 30.868 \text{ ft}^3/\text{lbm}$$

$$v_2 = (1/9.882)\, v_1 = 3.124 \text{ ft}^3/\text{lbm}$$

$$P_{meff} = \frac{w_{NET}}{v_1 - v_2} = \frac{323.19 \times 778}{(30.868 - 3.124)\ 144} = \mathbf{62.937\ psia}$$

Now we can find the power from Eq.10.11

$$\dot{W} = P_{meff}\, V_{displ} \frac{RPM}{60} \frac{1}{2} = 62.937 \times \frac{85}{12} \times \frac{2500}{60} \times \frac{1}{2} = \mathbf{9287.6\ lbf\text{-}ft/s}$$

$$= \mathbf{16.9\ hp}$$

Recall 1 hp = 550 lbf-ft/s.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.156E

A for stroke gasoline engine has a compression ratio of 10:1 with 4 cylinders of total displacement 75 in^3. the inlet state is 500 R, 10 psia and the engine is running at 2100 RPM with the fuel adding 600 Btu/lbm in the combustion process. What is the net work in the cycle and how much power is produced?

Solution:

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2$

$$\eta_{TH} = 1 - r_v^{1-k} = 1 - 10^{-0.4} = \mathbf{0.602}$$

$$w_{net} = \eta_{TH} \times q_H = 0.602 \times 600 = 361.2 \text{ Btu/lbm}$$

We also need specific volume to evaluate Eqs.10.9 to 10.11

$$v_1 = RT_1 / P_1 = 53.34 \times 500 / (10 \times 144) = 18.52 \text{ ft}^3/\text{lbm}$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = \frac{w_{net}}{v_1 (1 - \frac{1}{r_v})} = \frac{361.2}{18.52 \times 0.9} \frac{778}{144} = 117.1 \text{ psia}$$

Now we can find the power from Eq.10.11

$$\dot{W} = P_{meff} V_{displ} \frac{RPM}{60} \frac{1}{2} = 117.1 \times \frac{75}{12} \times \frac{2100}{60} \times \frac{1}{2} = \mathbf{12\ 808\ lbf\text{-}ft/s}$$

$$= \mathbf{23\ hp}$$

Recall 1 hp = 550 lbf-ft/s.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.157E

An Otto cycle has the lowest T as 520 R and the lowest P as 22 psia, the highest T is 4500 R and combustion adds 500 Btu/lbm as heat transfer. Find the compression ratio and the mean effective pressure.

Solution:

Identify states: $T_1 = 520$ R, $P_1 = 22$ psia, $T_3 = 4500$ R, $q_H = 500$ Btu/lbm

Combustion: $q_H = u_3 - u_2 = C_{vo}(T_3 - T_2) = 500$ Btu/lbm

$$T_2 = T_3 - q_H / C_{vo} = 4500 - 500/0.171 = 1576 \text{ R}$$

Compression: $CR = r_v = v_1/v_2 = (T_2/T_1)^{1/(k-1)} = \left(\frac{1576}{520}\right)^{2.5} =$ **15.99**

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2 = 15.99$

$$\eta_{TH} = 1 - r_v^{1-k} = 1 - T_1/T_2 = 1 - 520/1576 = 0.670$$

$$w_{net} = \eta_{TH} \times q_H = 0.670 \times 500 = 335 \text{ Btu/lbm}$$

We also need specific volume to evaluate Eqs.10.9 to 10.11

$$v_1 = RT_1 / P_1 = (53.34/144) \times 520 / 22 = 8.755 \text{ ft}^3/\text{lbm}$$

$$v_2 = v_1/CR = 0.5475 \text{ ft}^3/\text{lbm}$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = \frac{335}{8.755 - 0.5475} \frac{\text{Btu/lbm}}{\text{ft}^3/\text{lbm}} \times \frac{778 \text{ lbf-ft/Btu}}{144 \text{ (in/ft)}^2}$$

$$= \mathbf{220.5 \text{ psia}}$$

Comment: This is too high a compression ratio for a standard Otto cycle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.158E

A gasoline engine has a volumetric compression ratio of 10 and before compression has air at 520 R, 12.2 psia in the cylinder. The combustion peak pressure is 900 psia. Assume cold air properties. What is the highest temperature in the cycle? Find the temperature at the beginning of the exhaust (heat rejection) and the overall cycle efficiency.

Solution:

Compression. Isentropic so we use Eqs.6.24-6.25

$$P_2 = P_1(v_1/v_2)^k = 12.2\ (10)^{1.4} = 306.45 \text{ psia}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 520\ (10)^{0.4} = 1306.2 \text{ R}$$

Combustion. Constant volume

$$T_3 = T_2\ (P_3/P_2) = 1306.2 \times 900/306.45 = \mathbf{3836\ R}$$

Exhaust. Isentropic expansion so from Eq.6.23

$$T_4 = T_3 / (v_1/v_2)^{k-1} = T_3 / 10^{0.4} = 3836 / 2.5119 = \mathbf{1527\ R}$$

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2$

$$\eta = 1 - r_v^{1-k} = 1 - 10^{-0.4} = \mathbf{0.602}$$

Comment: No actual gasoline engine has an efficiency that high, maybe 35%.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.159E

The cycle in Problem 10.157E is used in a 150 in.^{3} engine running at 1800 RPM. How much power does it produce?

Identify states: $T_1 = 520$ R, $P_1 = 12$ psia, $T_3 = 4500$ R, $q_H = 500$ Btu/lbm

Combustion: $q_H = u_3 - u_2 = C_{vo}(T_3 - T_2) = 500$ Btu/lbm

$$T_2 = T_3 - q_H / C_{vo} = 4500 - 500/0.171 = 1576 \text{ R}$$

Compression: $CR = r_v = v_1/v_2 = (T_2/T_1)^{1/(k-1)} = \left(\frac{1576}{520}\right)^{2.5} =$ **15.99**

Overall cycle efficiency is from Eq.10.12, $r_v = v_1/v_2 = 15.99$

$$\eta_{TH} = 1 - r_v^{1-k} = 1 - T_1/T_2 = 1 - 520/1576 = 0.670$$

$$w_{net} = \eta_{TH} \times q_H = 0.670 \times 500 = 335 \text{ Btu/lbm}$$

We also need specific volume to evaluate Eqs.10.9 to 10.11

$$v_1 = RT_1 / P_1 = (53.34/144) \times 520 / 22 = 8.755 \text{ ft}^3/\text{lbm}$$

$$v_2 = v_1/CR = 0.5475 \text{ ft}^3/\text{lbm}$$

$$P_{meff} = \frac{w_{net}}{v_1 - v_2} = \frac{335}{8.755 - 0.5475} \frac{\text{Btu/lbm}}{\text{ft}^3/\text{lbm}} \times \frac{778 \text{ lbf-ft/Btu}}{144 \text{ (in/ft)}^2}$$

$$= 220.5 \text{ psia}$$

Now we can find the power from Eq.10.11

$$\dot{W} = P_{meff} V_{displ} \frac{RPM}{60} \frac{1}{2} = 220.5 \frac{\text{lbf}}{\text{in}^2} \times 150 \text{ in.}^3 \times \frac{1800}{60} \text{ (1/s)} \times \frac{1}{2}$$

$$= \textbf{41 344 lbf-ft/s = 75 hp = 53 Btu/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.160E

It is found experimentally that the power stroke expansion in an internal combustion engine can be approximated with a polytropic process with a value of the polytropic exponent *n* somewhat larger than the specific heat ratio *k*. Repeat Problem 10.154E but assume the expansion process is reversible and polytropic (instead of the isentropic expansion in the Otto cycle) with *n* equal to 1.50.

First find states 2 and 3. Based on the inlet state we get

$$v_4 = v_1 = RT_1/P_1 = 53.34\times510/13\times144 = 14.532 \text{ ft}^3/\text{lbm}$$

$$v_3 = v_2 = v_1/7 = 2.076 \text{ ft}^3/\text{lbm}$$

After compression we have constant s leads to Eq.6.24 and Eq.6.25

$$P_2 = P_1(v_1/v_2)^k = 13(7)^{1.4} = 198.2 \text{ lbf/in}^2$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 510(7)^{0.4} = 1110.7 \text{ R}$$

Constant volume combustion

$$T_3 = T_2 + q_H/C_{V0} = 1110.7 + 800/0.171 = 5789 \text{ R}$$

$$P_3 = P_2T_3/T_2 = 198.2 \times 5789/1110.7 = 1033 \text{ lbf/in}^2$$

Process 3 to 4: $Pv^{1.5}$ = constant.

$$P_4 = P_3(v_3/v_4)^{1.5} = 1033(1/7)^{1.5} = 55.78 \text{ lbf/in}^2$$

$$T_4 = T_3(v_3/v_4)^{0.5} = 5789(1/7)^{0.5} = 2188 \text{ R}$$

For the mean effective pressure we need the net work and therefore the induvidual process work terms

$$_1w_2 = \int P\,dv = R(T_2 - T_1)/(1 - 1.4)$$

$$= -53.34(1110.7 - 510)/(0.4\times778) = -102.96 \text{ Btu/lbm}$$

$$_3w_4 = \int P\,dv = R(T_4 - T_3)/(1 - 1.5)$$

$$= -53.34(2188 - 5789)/(0.5\times778) = 493.8 \text{ Btu/lbm}$$

$$w_{NET} = 493.8 - 102.96 = 390.84 \text{ Btu/lbm}$$

$$\eta_{CYCLE} = w_{NET}/q_H = 390.84/700 = \mathbf{0.488}$$

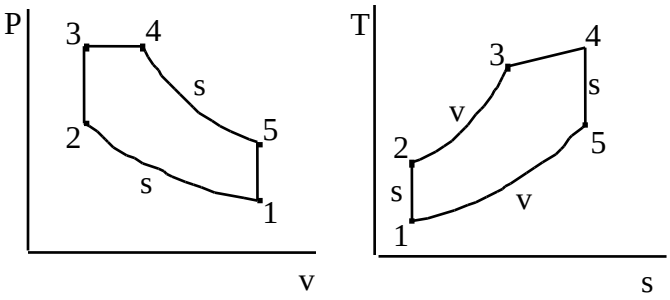
$$P_{meff} = w_{NET}/(v_1-v_2) = 390.84\times778/(14.532 - 2.076) = \mathbf{169.5 \text{ lbf/in}^2}$$

Notice a smaller w_{NET}, η_{CYCLE}, P_{meff} compared to ideal cycle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.161E

In the Otto cycle all the heat transfer q_H occurs at constant volume. It is more realistic to assume that part of q_H occurs after the piston has started its downwards motion in the expansion stroke. Therefore consider a cycle identical to the Otto cycle, except that the first two-thirds of the total q_H occurs at constant volume and the last one-third occurs at constant pressure. Assume the total q_H is 700 Btu/lbm, that the state at the beginning of the compression process is 13 lbf/in.^{2}, 68 F, and that the compression ratio is 9. Calculate the maximum pressure and temperature and the thermal efficiency of this cycle. Compare the results with those of a conventional Otto cycle having the same given variables.



$P_1 = 13$ psia, $T_1 = 527.67$ R

$r_V = v_1/v_2 = 7$

$$q_{23} = \frac{2}{3}\times 700 = 466.7 \frac{\text{Btu}}{\text{lbm}}$$

$$q_{34} = \frac{1}{3}\times 700 = 233.3 \frac{\text{Btu}}{\text{lbm}}$$

Constant s compression, Eqs.6.24-25

$$P_2 = P_1(v_1/v_2)^k = 13(9)^{1.4} = 281.8 \text{ lbf/in}^2$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 527.67(9)^{0.4} = 1270.7 \text{ R}$$

Constant v combustion

$$T_3 = T_2 + q_{23}/C_{V0} = 1270.7 + 466.7/0.171 = 4000 \text{ R}$$

$$P_3 = P_2(T_3/T_2) = 281.8 \times 4000/1270.7 = \mathbf{887.1\ lbf/in^2} = P_4$$

Constant P combustion

$$T_4 = T_3 + q_{34}/C_{P0} = 4000 + 233.3/0.24 = \mathbf{4972\ R}$$

Remaining expansion: $$\frac{v_5}{v_4} = \frac{v_1}{v_4} = (P_4/P_1) \times (T_1/T_4) = \frac{88.1}{13} \times \frac{527.67}{4972} = 7.242$$

$$T_5 = T_4(v_4/v_5)^{k-1} = 4972(1/7.242)^{0.4} = 2252 \text{ R}$$

$$q_L = C_{V0}(T_5 - T_1) = 0.171(2252 - 527.67) = 294.9 \text{ Btu/lbm}$$

$$\eta_{TH} = 1 - q_L/q_H = 1 - 294.9/700 = \mathbf{0.579}$$

Standard Otto cycle: $$\eta_{TH} = 1 - (9)^{-0.4} = \mathbf{0.585}$$

10.162E

A diesel engine has a bore of 4 in., a stroke of 4.3 in. and a compression ratio of 19:1 running at 2000 RPM (revolutions per minute). Each cycle takes two revolutions and has a mean effective pressure of 200 lbf/in.^{2}. With a total of 6 cylinders find the engine power in Btu/s and horsepower, hp.

Solution:

Work from mean effective pressure, Eq.10.9.

$$P_{meff} = w_{net} / (v_{max} - v_{min}) \quad \rightarrow \quad w_{net} = P_{meff} (v_{max} - v_{min})$$

The displacement is

$$\Delta V = \pi Bore^2 \times 0.25 \times S = \pi \times 4^2 \times 0.25 \times 4.3 = 54.035 \text{ in}^3$$

Work per cylinder per power stroke, Eq.10.10

$$W = P_{meff}(V_{max} - V_{min}) = 200 \times 54.035 / (12 \times 778) = 1.1575 \text{ Btu/cycle}$$

Only every second revolution has a power stroke so we can find the power, see also Eq.10.11

$$\dot{W} = W \times N_{cyl} \times RPM \times 0.5 \left(\frac{\text{cycles}}{\text{min}}\right) \left(\frac{\text{min}}{60 \text{ s}}\right) \left(\frac{\text{Btu}}{\text{cycle}}\right)$$

$$= 1.1575 \times 6 \times 2000 \times 0.5 \times (1/60) = 115.75 \text{ Btu/s}$$

$$= 115.75 \times 3600/2544.43 \text{ hp} = \mathbf{164 \ hp}$$

The conversion factor from Btu/s to hp is from Table A.1 under power.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.163E

A super charger is used for a diesel engine so intake is 30 psia, 580 R. The cycle has compression ratio of 18:1 and the mean effective pressure is 120 psia. If the engine is 600 in.^{3} running at 200 RPM find the power output.

Solution:

The power is from Eq.10.11

$$\dot{W} = m\, w_{net} \times N_{cyl} \times RPM \times 1/60$$

$$= m\, P_{meff} (v_1 - v_2) \times N_{cyl} \times RPM/60 = P_{meff}\, V_{displ}\, RPM/60$$

$$= 120 \frac{lbf}{in^2} \times 600 \text{ in.}^3 \times (200 / 60)\ (1/s)$$

$$= \mathbf{20\ 000\ lbf\text{-}ft/s = 25.7\ Btu/s = 36.6\ hp}$$

Comment: multiply with ½ if this is a four stroke engine

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.164E

At the beginning of compression in a diesel cycle T = 540 R, P = 30 lbf/in.^{2} and the state after combustion (heat addition) is 2600 R and 1000 lbf/in.^{2}. Find the compression ratio, the thermal efficiency and the mean effective pressure.

Solution:

Compression process (isentropic) from Eq.6.28 or p295

$$P_2 = P_3 = 1000 \text{ lbf/in}^2 \quad \Rightarrow \quad v_1/v_2 = (P_2/P_1)^{1/k} = (1000/30)^{0.7143} = \mathbf{12.24}$$

$$T_2 = T_1(P_2/P_1)^{(k-1)/k} = 540(1000/30)^{\,0.2857} = 1470.6 \text{ R}$$

Expansion process (isentropic) first get the volume ratios

$$v_3/v_2 = T_3/T_2 = 2600/1470.6 = 1.768$$

$$v_4/v_3 = v_1/v_3 = (v_1/v_2)(v_2/v_3) = 12.24/1.768 = 6.923$$

The exhaust temperature follows from state 3 and constant s, Eq.6.24

$$T_4 = T_3(v_3/v_4)^{k-1} = 2600*6.923^{-0.4} = 1199 \text{ R}$$

$$q_L = C_V(T_4 - T_1) = 0.171(1199\text{-}540) = 112.7 \text{ Btu/lbm}$$

$$q_H = h_3 - h_2 = C_P(T_3 - T_2) = 0.24(2600 - 1470.6) = 271.1 \text{ Btu/lbm}$$

Overall performance

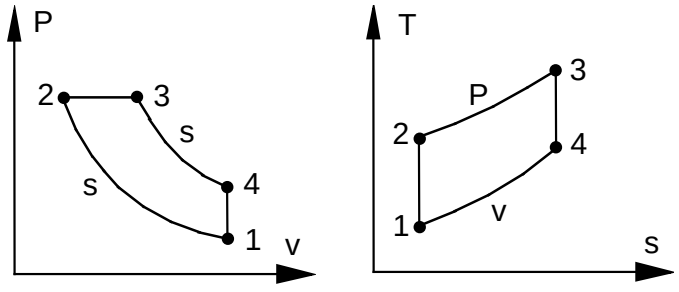
$$\eta = 1 - q_L/q_H = 1 - 112.7 / 271.1 = \mathbf{0.5843}$$

$$w_{net} = q_{net} = 271.1 - 112.7 = 158.4 \text{ Btu/lbm}$$

$$v_{max} = v_1 = RT_1/P_1 = 53.34 \times 540/(30 \times 144) = 6.6675 \text{ ft}^3\text{/lbm}$$

$$v_{min} = v_{max}(v_1/v_2) = 6.6675 / 12.24 = 0.545 \text{ ft}^3\text{/lbm}$$

$$P_{meff} = \frac{w_{net}}{v_{max} - v_{min}} = \frac{158.4}{6.6675 - 0.545} \times \frac{778}{144} = \mathbf{139.8 \text{ lbf/in}^2}$$



Remark: This is a too low compression ratio for a practical diesel cycle.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.165E

The **cut off ratio** is the ratio of v_3/v_2, see Fig. 10.18, which is the expansion while combustion occurs at constant pressure. Determine this ratio for the cycle in Problem 10.164E.

Compression process (isentropic) from Eqs.6.23-25

$$T_2 = T_1(P_2/P_1)^{(k-1)/k} = 540(1000/30)^{0.2857} = 1470.6 \text{ R}$$

Cut-off ratio: $v_3 / v_2 = T_3 / T_2 = 2600/1470.6 =$ **1.768**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.166E

A diesel cycle has state 1 as 14 lbf/in.^{2}, 63 F and a compression ratio of 20. For a maximum temperature of 4000 R find the cycle efficiency.

Diesel cycle: $P_1 = 14$ psia, $T_1 = 522.67$ R, CR = $v_1/v_2 = 20$

From the inlet state and the compression we get

$$T_2 = T_1(v_1/v_2)^{k-1} = 522.67 \text{ R } (20)^{0.4} = 1732.4 \text{ R}$$

$$v_1 = \frac{53.34 \times 522.67}{14 \times 144} = 13.829 \text{ ft}^3/\text{lbm}, \qquad v_2 = \frac{13.829}{20} = 0.6915 \text{ ft}^3/\text{lbm}$$

Constant pressure combustion relates v_3 and T_3

$$v_3 = v_2 \times T_3/T_2 = 0.6915 \times 4000/1732.4 = 1.5966 \text{ ft}^3/\text{lbm}$$

Expansion process (isentropic and $v_4 = v_1$) from Eq.6.24

$$T_4 = T_3(v_3 / v_4)^{0.4} = 4000 \text{ R } (1.5966 / 13.829)^{0.4} = 1686.6 \text{ R}$$

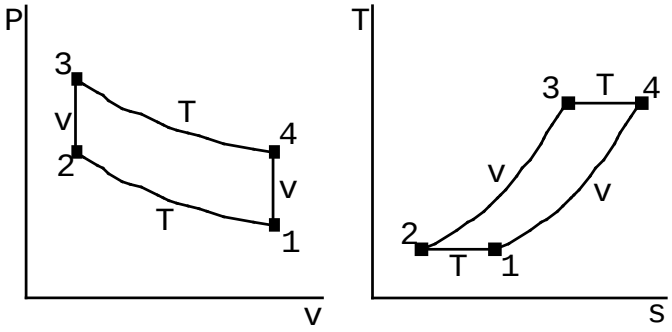
Cycle net work and efficiency

$$\eta_{TH} = 1 - \frac{T_4 - T_1}{k(T_3 - T_2)} = 1 - \frac{1686.6 - 522.67}{1.4\ (4000 - 1732.4)} = \mathbf{0.633}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.167E

Consider an ideal Stirling-cycle engine in which the pressure and temperature at the beginning of the isothermal compression process are 14.7 lbf/in.^{2}, 80 F, the compression ratio is 6, and the maximum temperature in the cycle is 2000 F. Calculate the maximum pressure in the cycle and the thermal efficiency of the cycle with and without regenerators.



Ideal Stirling cycle

$T_1 = T_2 = 80$ F

$P_1 = 14.7$ lbf/in^2

$\frac{v_1}{v_2} = 6$

$T_3 = T_4 = 2000$ F

Isothermal compression (heat goes out)

$$T_1 = T_2 \rightarrow \quad P_2 = P_1 \times v_1/v_2 = 14.7 \times 6 = 88.2$$

$$w_{12} = q_{12} = -RT_1 \ln \frac{v_1}{v_2} = -\frac{53.34}{778} \times 540 \ln 6 = -66.3 \text{ Btu/lbm}$$

Constant volume heat addition

$$V_2 = V_3 \rightarrow P_3 = P_2 \times T_3/T_2 = 88.2 \times \frac{2460}{540} = \mathbf{401.8\ lbf/in^2}$$

$$q_{23} = C_{V0}(T_3 - T_2) = 0.171\ (2460-540) = 328.3 \text{ Btu/lbm}$$

Isothermal expansion (heat comes in)

$$w_{34} = q_{34} = RT_3 \ln (v_4/v_3)$$

$$= (53.34/778) \times 2460 \ln 6 = 302.2 \text{ Btu/lbm}$$

$$w_{NET} = 302.2 - 66.3 = 235.9 \text{ Btu/lbm}$$

Efficiency without regenerator, (q_{23} and q_{34} are coming in from source)

$$\eta_{\text{NO REGEN}} = \frac{235.9}{302.2+328.3} = \mathbf{0.374,}$$

Efficiency with regenerator, (Now only q_{34} is coming in from source)

$$\eta_{\text{WITH REGEN}} = \frac{235.9}{302.2} = \mathbf{0.781}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.168E

Air in a piston/cylinder goes through a Carnot cycle in which T_L = 560 R and the total cycle efficiency is $\eta = 2/3$. Find T_H, the specific work and volume ratio in the adiabatic expansion for constant C_p, C_v.

Carnot cycle efficiency from Eq.5.5

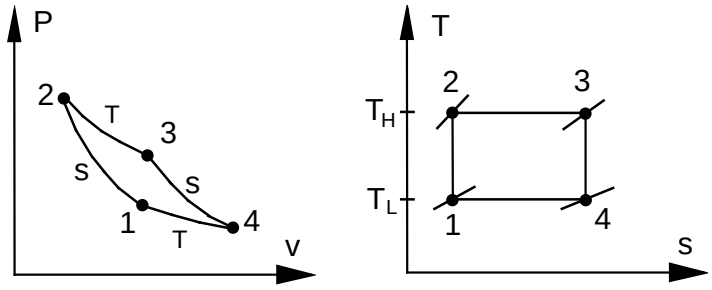
$$\eta = 1 - T_L/T_H = 2/3 \Rightarrow \quad T_H = 3 \times T_L = 3 \times 560 = \mathbf{1680\ R}$$

Adiabatic expansion 3 to 4: Pv^k = constant, work from Eq.6.29 (n = k)

$${}_3w_4 = (P_4v_4 - P_3v_3)/(1 - k) = [R/(1-k)](T_4 - T_3) = u_3 - u_4$$

$$= C_v(T_3 - T_4) = 0.171 \text{ Btu/lbm-R } (1680 - 540) \text{ R} = \mathbf{194.94\ Btu/lbm}$$

$$v_4/v_3 = (T_3/T_4)^{1/(k-1)} = 3^{2.5} = \mathbf{15.6}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.169E

Do the previous problem 10.168E using Table F.5.

Air in a piston/cylinder goes through a Carnot cycle in which T_L = 560 R and the total cycle efficiency is $\eta = 2/3$. Find T_H, the specific work and volume ratio in the adiabatic expansion for constant C_p, C_v.

Carnot cycle:

$$\eta = 1 - T_L/T_H = 2/3 \Rightarrow \quad T_H = 3 \times T_L = 3 \times 560 = \mathbf{1680\ R}$$

$$_3w_4 = u_3 - u_4 = 302.124 - 95.589 = \mathbf{206.535\ Btu/lbm}$$

Adiabatic expansion 3 to 4: $\quad s_4 = s_3 \quad \Rightarrow \quad$ Eq.6.19

$$s^o_{T4} = s^o_{T3} + R \ln \frac{P_4}{P_3} \quad \Rightarrow \quad \text{Table F.5 for standard entropy}$$

$$\frac{P_4}{P_3} = \exp\left[(s^o_{T4} - s^o_{T3})/R\right] = \exp\left[\frac{1.64852 - 1.92338}{53.34/778}\right] = 0.018151$$

Ideal gas law then gives

$$\frac{v_4}{v_3} = \frac{T_4}{T_3} \times \frac{P_3}{P_4} = \frac{560}{1680} \times \frac{1}{0.018151} = \mathbf{18.36}$$

Atkinson and Miller cycles

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.170E

An Atkinson cycle has state 1 as 20 psia, 540 R, compression ratio of 9 and expansion ratio of 14. Find the needed heat release in the combustion.

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq. 6.24 and Eq. 6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 540 \times 9^{0.4} = 1300.4 \text{ R}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 20 \times 9^{1.4} = 433.5 \text{ psi}$$

The expansion backwards from $P_4 = P_1$ gives

$$P_3 = P_4 \times (v_4/v_3)^{k} = P_4 \times CR^{k} = 20 \times 14^{1.4} = 804.65 \text{ psi}$$

Combustion 2 to 3 at constant volume: $v_3 = v_2 \Rightarrow P_3 = P_2 \times (T_3/T_2)$

Energy Eq.: $u_3 = u_2 + q_H \quad \Rightarrow \quad q_H = C_v (T_3 - T_2)$

Solve for T_3 from process equation

$$T_3 = T_2 \times (P_3 / P_2) = 1300.4 \text{ R} \times (804.65 / 433.5) = 2413.8 \text{ R}$$

Solve for q_H from the energy equation

$$q_H = C_v (T_3 - T_2) = 0.171 (2413.8 - 1300.4) = \mathbf{190.4 \text{ Btu/lbm}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.171E

Assume we change the Otto cycle in Problem 10.152E to an Atkinson cycle by keeping the same conditions and only increase the expansion to give a different state 4. Find the expansion ratio and the cycle efficiency.

Solution:

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 540 \times 10^{0.4} = 1356.4 \text{ R}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 14 \times 10^{1.4} = 351.7 \text{ psi}$$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$$T_3 = T_2 + q_H/C_v = 1356.4 + 560/0.171 = \mathbf{4631\ R}$$

$$P_3 = P_2 \times (T_3/T_2) = 351.7 \text{ lbf/in}^2 \times (4631 / 1356.4) = \mathbf{1201\ lbf/in^2}$$

The expansion should now bring pressure down so $P_4 = P_1$

$$P_4 = P_1 = P_3 \times (v_3/v_4)^{k} = P_3 \times CR^{-k} \Rightarrow CR = (P_3 /P_4)^{1/k}$$

$$CR = (1201 / 14)^{0.71429} = \mathbf{24.04}$$

So now the efficiency becomes

$$\eta = 1 - k \frac{CR - CR_1}{CR^k - CR_1^k} = 1 - 1.4 \frac{24.04 - 10}{24.04^{\,k} - 10^{\,k}} = \mathbf{0.676}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.172E

An Atkinson cycle has state 1 as 20 psia, 540 R, compression ratio of 9 and expansion ratio of 14. Find the mean effective pressure.

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 540 \times 9^{0.4} = 1300.4 \text{ R}$$

$$P_2 = P_1 \times (v_1/v_2)^k = 20 \times 9^{1.4} = 433.5 \text{ psia}$$

The expansion backwards from $P_4 = P_1$ gives

$$P_3 = P_4 \times (v_4/v_3)^k = P_4 \times CR^k = 20 \times 14^{1.4} = 804.65 \text{ psia}$$

Combustion 2 to 3 at constant volume: $v_3 = v_2 \Rightarrow P_3 = P_2 \times (T_3/T_2)$

Energy Eq.: $u_3 = u_2 + q_H \quad \Rightarrow \quad q_H = C_v (T_3 - T_2)$

Solve for T_3 from process equation

$$T_3 = T_2 \times (P_3 / P_2) = 1300.4 \times (804.65 / 433.5) = 2413.8 \text{ R}$$

Solve for q_H from the energy equation

$$q_H = C_v (T_3 - T_2) = 0.171 (2413.8 - 1300.4) = 190.4 \text{ Btu/lbm}$$

The efficiency and net work become

$$\eta_{TH} = 1 - k \frac{CR - CR_1}{CR^k - CR_1^k} = 1 - 1.4 \frac{14 - 9}{14^k - 9^k} = 0.623$$

$$w_{net} = \eta_{TH} \times q_H = 0.623 \times 190.4 = 118.6 \text{ Btu/lbm}$$

Displacement (we take this as $v_4 - v_2$) and P_{meff}

$$v_1 = RT_1/P_1 = 53.34 \times 540/(20 \times 144) = 10.00 \text{ ft}^3/\text{lbm}$$

$$v_2 = (1/9)\, v_1 = 1.111 \text{ ft}^3/\text{lbm}; \quad v_4 = 14\, v_2 = 15.5575 \text{ ft}^3/\text{lbm}$$

$$P_{meff} = \frac{w_{NET}}{v_4 - v_2} = \frac{118.6}{15.5575 - 1.111} \frac{778}{144} = \mathbf{44.35 \text{ psia}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.173E

A Miller cycle has state 1 as 20 psia, 540 R, compression ratio of 9 and expansion ratio of 14. If P_4 is 30 psia find the heat release in the combustion.

Solution:

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 540 \times 9^{0.4} = 1300.4 \text{ R}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 20 \times 9^{1.4} = 433.5 \text{ psia}$$

The expansion backwards from P_4 gives

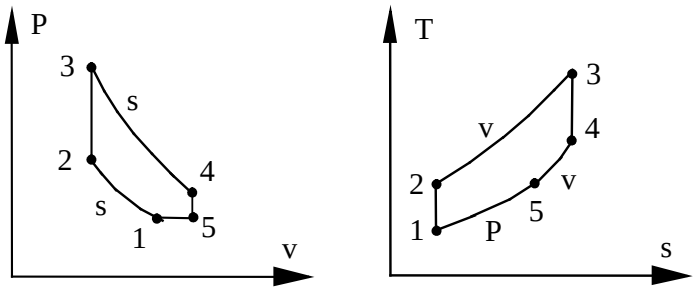
$$P_3 = P_4 \times (v_4/v_3)^{k} = P_4 \times CR^{k} = 30 \times 14^{1.4} = 1207 \text{ psia}$$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$$T_3 = T_2 + q_H/C_v \quad \text{and} \quad P_3 = P_2 \times (T_3/T_2)$$

$$T_3 = T_2 \times (P_3 / P_2) = 1300.4 \times (1207 / 433.5) = 3620.7 \text{ R}$$

$$q_H = C_v (T_3 - T_2) = 0.171 (3620.7 - 1300.4) = \mathbf{396.8 \text{ Btu/lbm}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.174E

A Miller cycle has state 1 as 20 psia, 540 R, compression ratio of 9 and a heat release of 430 Btu/lbm. Find the needed expansion ratio so P_4 is 30 psia.

Solve the problem with constant heat capacity.

Compression 1 to 2: $s_2 = s_1 \Rightarrow$ From Eq.6.24 and Eq.6.25

$$T_2 = T_1 (v_1/v_2)^{k-1} = 540 \times 9^{0.4} = 1300.4 \text{ R}$$

$$P_2 = P_1 \times (v_1/v_2)^{k} = 20 \times 9^{1.4} = 433.5 \text{ psia}$$

Combustion 2 to 3 at constant volume: $u_3 = u_2 + q_H$

$$T_3 = T_2 + q_H/C_v = 1300.4 + 430 / 0.171 = 3815 \text{ R}$$

$$P_3 = P_2 \times (T_3/T_2) = 433.5 \, (3815 / 1300.4) = 1271.8 \text{ psia}$$

The expansion should now bring pressure down to P_4

$$P_4 = P_3 \times (v_3/v_4)^{k} = P_3 \times CR^{-k} \Rightarrow CR = (P_3 / P_4)^{1/k}$$

$$CR = (1271.8 / 30)^{0.71429} = \mathbf{14.53}$$

Exergy, Combined Cycles and Review

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.175E

Consider the Brayton cycle in problem 10.144E. Find all the flows and fluxes of exergy and find the overall cycle second-law efficiency. Assume the heat transfers are internally reversible processes and we then neglect any external irreversibility.

Solution:

Efficiency is from Eq.10.1

$$\eta = \dot{W}_{NET}/\dot{Q}_H = \frac{w_{net}}{q_H} = 1 - r_p^{-(k-1)/k} = 1 - 16^{-0.4/1.4} = \mathbf{0.547}$$

from the required power we can find the needed heat transfer

$$\dot{Q}_H = \dot{W}_{net} / \eta = 14\,000 / 0.547 = 25\,594 \text{ Btu/s}$$

$$\dot{m} = \dot{Q}_H / q_H = 25\,594 \text{ (Btu/s)} / 400 \text{ Btu/lbm} = \mathbf{63.99 \text{ lbm/s}}$$

Temperature after compression is

$$T_2 = T_1 \, r_p^{(k-1)/k} = 519.67 \times 16^{0.4/1.4} = 1148 \text{ R}$$

The highest temperature is after combustion

$$T_3 = T_2 + q_H/C_p = 1148 + \frac{400}{0.24} = \mathbf{2815 \text{ R}}$$

For the exit flow I need the exhaust temperature

$$T_4 = T_3 \; r_p^{-(k-1)/k} = 2815 \times 16^{-0.2857} = 1274.8 \text{ R}$$

The high T exergy input from combustion is

$$\dot{\Phi}_H = \dot{m}(\psi_3 - \psi_2) = \dot{m}[h_3 - h_2 - T(s_3 - s_2)]$$

$$= 63.99 \, [400 - 536.67 \times 0.24 \ln (\frac{2815}{1148})] = \mathbf{17\,895 \text{ Btu/s}}$$

Since the low T exergy flow out is lost the second law efficiency is

$$\eta_{II} = \dot{W}_{NET}/\dot{\Phi}_H = 14\,000 / 17\,895 = \mathbf{0.782}$$

$$\dot{\Phi}_{flow\ out} = \dot{m}(\psi_4 - \psi_o) = \dot{m}[h_4 - h_o - T(s_4 - s_o)]$$

$$= 63.99 \, [\, 0.24(1274.8 - 536.7) - 536.7 \times 0.24 \ln (\frac{1274.8}{536.7}) \,] = \mathbf{4205 \text{ Btu/s}}$$

$$\dot{\Phi}_{flow\ in} = \dot{m}(\psi_1 - \psi_o) = \dot{m}[h_1 - h_o - T(s_1 - s_o)]$$

$$= 63.99 \, [\, 0.24(60 - 77) - 536.7 \times 0.24 \ln (\frac{519.7}{536.7}) \,] = \mathbf{4.2 \text{ Btu/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.176E

The Brayton cycle in problem 10.141E has a heat addition of 350 Btu/lbm. What is the exergy increase in this process?

Solution:

Combustion: $h_3 = h_2 + q_H$; $\quad {}_2w_3 = 0$ and $T_{max} = T_3 = 2500$ R

$T_2 = T_3 - q_H/C_P = 2500 - 350/0.24 = 1041.67$ R

Now the exergy increase from 2 to 3 becomes ($P_3 = P_2$)

$$\psi_3 - \psi_2 = h_3 - h_2 - T_0(s_3 - s_2) = q_H - T_0 C_P \ln(T_3/T_2)$$

$$= 350 - 536.7 \times 0.24 \ln \left(\frac{2500}{1041.67} \right)$$

$$= \mathbf{237.2\ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.177E

Solve Problem 10.149E assuming an isentropic turbine efficiency of 85% and a nozzle efficiency of 95%.

Solution:

C.V. Turbine: $h_i = 560.588$ Btu/lbm, $s^o_{Ti} = 1.99765$ Btu/lbm R, $s_{es} = s_i$

Then from Eq.6.19

$$\Rightarrow s^o_{Tes} = s^o_{Ti} + R \ln(P_e/P_i) = 1.99765 + \frac{53.34}{778} \ln (35/220) = 1.8716 \frac{\text{Btu}}{\text{lbm R}}$$

Table F.5 $T_{es} = 1382$ R, $h_{es} = 338.27$ Btu/lbm,

Energy eq.: $w_{T,s} = h_i - h_{es} = 560.588 - 338.27 = 222.3$ Btu/lbm

Eq.7.27: $w_{T,AC} = w_{T,s} \times \eta_T = 188.96 = h_i - h_{e,AC} \Rightarrow h_{e,AC} = 371.6$

Table F.5 $\Rightarrow$ $\mathbf{T_{e,AC} = 1509\ R}$, $s^o_{Te} = 1.8947$ Btu/lbm R

C.V. Nozzle: $h_i = 371.6$ Btu/lbm, $s^o_{Ti} = 1.8947$ Btu/lbm R, $s_{es} = s_i$

Then from Eq.6.19

$$\Rightarrow s^o_{Tes} = s^o_{Ti} + R \ln(P_e/P_i) = 1.8947 + \frac{53.34}{778} \ln (\frac{14.7}{35}) = 1.8352 \frac{\text{Btu}}{\text{lbm R}}$$

Table F.5 $\Rightarrow$ $T_{e,s} = 1199.6$ R, $h_{e,s} = 291.3$ Btu/lbm

Energy Eq.: $(1/2)\mathbf{V}^2_{e,s} = h_i - h_{e,s} = 371.6 - 291.3 = 80.3$ Btu/lbm

Eq.7.30: $(1/2)\mathbf{V}^2_{e,AC} = (1/2)\mathbf{V}^2_{e,s} \times \eta_{NOZ} = 76.29$ Btu/lbm

$$\mathbf{V}_{e,AC} = \sqrt{2 \times 25037 \times 76.29} = \mathbf{1954\ ft/s}$$

Recall 1 Btu/lbm = 25 037 ft^2/s^2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.178E

Solve Problem 10.141E with variable specific heats using Table F.5.

In a Brayton cycle the inlet is at 540 R, 14 psia and the combustion adds 350 Btu/lbm. The maximum temperature is 2500 R due to material considerations. Find the maximum permissible compression ratio and for that the cycle efficiency using cold air properties.

Solution:

Combustion: $h_3 = h_2 + q_H$; $\quad {}_2w_3 = 0$ and $T_{max} = T_3 = 2500$ R

$$h_2 = h_3 - q_H = 645.721 - 350 = 295.72 \text{ Btu/lbm}$$

From Table F.5 find T_2 from h_2

$$T_2 = 1216.8 \text{ R}; \quad s^o_{T2} = 1.83883 ; \quad T_1 = 540 \text{ R}; \quad s^o_{T1} = 1.63979 \text{ Btu/lbm-R}$$

Reversible adiabatic compression leads to constant s, from Eq.6.19:

$$P_2 / P_1 = \exp[\ (s^o_{T2} - s^o_{T1})/R\ ] = \exp(2.90313) = \mathbf{18.231}$$

Reversible adiabatic expansion leads to constant s, from Eq.6.19

$$s^o_{T4} = s^o_{T3} + R \ln(P_4/P_3) = 2.03391 + \frac{53.34}{778} \ln \frac{1}{18.231} = 1.83487 \text{ Btu/lbm-R}$$

From Table F.5.1 by linear interpolation $\quad T_4 = 1197.9$ R, $\quad h_4 = 290.905$ Btu/lbm

$$w_T = h_3 - h_4 = 645.721 - 290.905 = 354.82 \text{ Btu/lbm}$$

$$w_C = h_2 - h_1 = 295.72 - 129.18 = 166.54 \text{ Btu/lbm}$$

$$w_{net} = w_T - w_C = 354.82 - 166.54 = \mathbf{188.28} \text{ Btu/lbm}$$

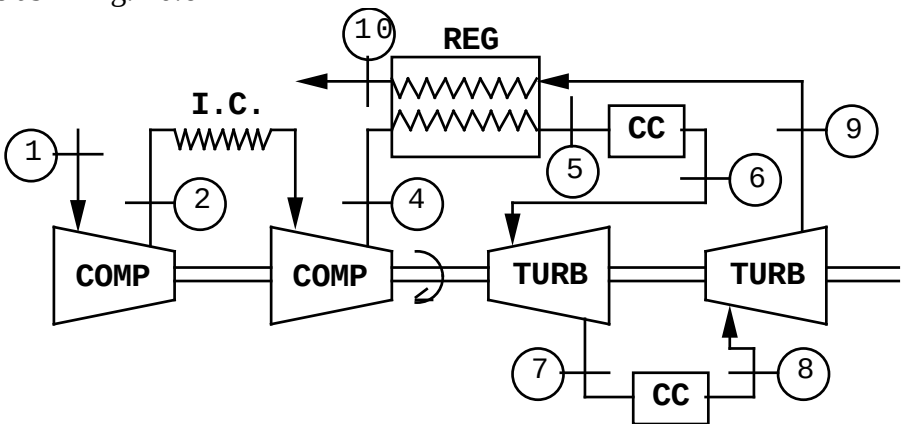
$$\eta = w_{net} / q_H = 188.28 / 350 = \mathbf{0.538}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.179E

Consider an ideal gas-turbine cycle with two stages of compression and two stages of expansion. The pressure ratio across each compressor stage and each turbine stage is 8 to 1. The pressure at the entrance to the first compressor is 14 lbf/in.^{2}, the temperature entering each compressor is 70 F, and the temperature entering each turbine is 2000 F. An ideal regenerator is also incorporated into the cycle. Determine the compressor work, the turbine work, and the thermal efficiency of the cycle.

This is as in Fig. 10.6



$P_2/P_1 = P_4/P_3 = P_6/P_7 = P_8/P_9 = 8.0$

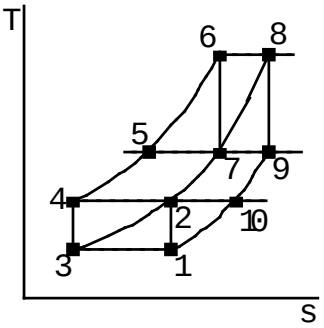
$P_1 = 14$ lbf/in^2

$T_1 = T_3 = 70$ F, $T_6 = T_8 = 2000$ F

Assume const. specific heat

$s_2 = s_1$ and $s_4 = s_3$

$$T_4 = T_2 = T_1(P_2/P_1)^{\frac{k-1}{k}} = 529.67(8)^{0.2857} = 959.4 \text{ R}$$



Total compressor work

$$-w_C = 2 \times (-w_{12}) = 2C_{P0}(T_2 - T_1) = 2 \times 0.24(959.4 - 529.67) = \mathbf{206.3\ Btu/lbm}$$

Also $s_6 = s_7$ and $s_8 = s_9$

$$\Rightarrow\ T_7 = T_9 = T_6\left(\frac{P_7}{P_6}\right)^{\frac{k-1}{k}} = 2459.67\left(\frac{1}{8}\right)^{0.2857} = 1357.9 \text{ R}$$

Total turbine work

$$w_T = 2 \times w_{67} = 2C_{P0}(T_6 - T_7) = 2 \times 0.24(2459.67 - 1357.9) = 528.85 \text{ Btu/lbm}$$

$$w_{NET} = 528.85 - 206.3 = 322.55 \text{ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Ideal regenerator: $T_5 = T_9$, $T_{10} = T_4$

$$\Rightarrow q_H = (h_6 - h_5) + (h_8 - h_7) = 2C_{P0}(T_6 - T_5)$$

$$= 2 \times 0.24(2459.67 - 1357.9) = w_T = 528.85 \text{ Btu/lbm}$$

$$\eta_{TH} = w_{NET}/q_H = 322.55/528.85 = \mathbf{0.61}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.180E

Consider an ideal air-standard diesel cycle where the state before the compression process is 14 lbf/in.^{2}, 63 F and the compression ratio is 20. Find the maximum temperature (by iteration) in the cycle to have a thermal efficiency of 60%.

Diesel cycle: $P_1 = 14$, $T_1 = 522.67$ R, $v_1/v_2 = 20$, $\eta_{TH} = 0.60$

From the inlet state and the compression we get

$$T_2 = T_1(v_1/v_2)^{k-1} = 522.67(20)^{0.4} = 1732.4 \text{ R}$$

$$v_1 = \frac{53.34 \times 522.67}{14 \times 144} = 13.829 \text{ ft}^3/\text{lbm}, \qquad v_2 = \frac{13.829}{20} = 0.6915 \text{ ft}^3/\text{lbm}$$

Constant pressure combustion relates v_3 and T_3

$$v_3 = v_2 \times T_3/T_2 = 0.6915 \times T_3/1732.4 = 0.000399\, T_3$$

The expansion then gives T_4 interms of T_3

$$\frac{T_3}{T_4} = \left(\frac{v_4}{v_3}\right)^{k-1} = \left(\frac{13.829}{0.000399\, T_3}\right)^{0.4} \rightarrow \qquad T_4 = 0.0153\, T_3^{1.4}$$

Now these T's relate to the given efficiency

$$\eta_{TH} = 0.60 = 1 - \frac{T_4 - T_1}{k(T_3 - T_2)} = 1 - \frac{0.0153\, T_3^{1.4} - 522.67}{1.4(T_3 - 1732.4)}$$

$$\Rightarrow \quad 0.0153\, T_3^{1.4} - 0.56\, T_3 + 447.5 = 0$$

Trial and error on this non-linear equation

5100 R: LHS = -35.54, 5500 R: LHS = 5.04, 5450 R: LHS = -0.5

Linear interpolation, $T_3 =$ **5455 R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

10.181E

Repeat Problem 10.179E, but assume that each compressor stage and each turbine stage has an isentropic efficiency of 85%. Also assume that the regenerator has an efficiency of 70%.

$T_{4S} = T_{2S} = 959.4$ R, $-w_{CS} = 206.3$

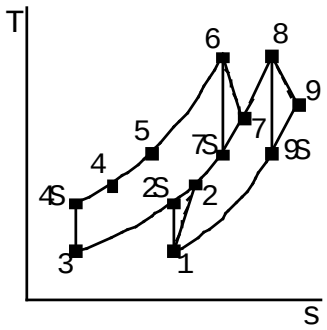
$T_{7S} = T_{9S} = 1357.9$ R, $w_{TS} = 528.85$

$\Rightarrow \quad w_C = w_{SC}/\eta_{SC} = 242.7$ Btu/lbm

$w_{12} = w_{34} = 242.7/2 = 121.35$ Btu/lbm

$T_2 = T_4 = T_1 + w_{12}/C_{P0}$

$= 529.67 + 121.35/0.24 = 1035.3$ R



$w_T = \eta_T w_{TS} = 0.85 \times 528.85 = 449.5$ Btu/lbm

Energy Eq. for actual turbines

$T_7 = T_9 = T_6 - w_{67}/C_{P0} = 2459.67 - 449.5/2{\times}0.24 = 1523$ R

Regenerator efficiency

$$\eta_{REG} = \frac{h_5 - h_4}{h_9 - h_4} = \frac{T_5 - T_4}{T_9 - T_4} = \frac{T_5 - 1035.3}{1523 - 1035.3} = 0.7 \quad \Rightarrow \; T_5 = 1376.7 \text{ R}$$

The two combustors, heat addition

$q_H = C_{P0}(T_6 - T_5) + C_{P0}(T_8 - T_7)$

$= 0.24(2459.67 - 1376.7) + 0.24(2459.67 - 1523)$

$= 484.7$ Btu/lbm

$w_{NET} = w_T + w_C = 449.5 - 242.7 = 206.8$ Btu/lbm

$\eta_{TH} = w_{NET}/q_H = 206.8/484.7 =$ **0.427**

In-Text Concept Questions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.a

Are the mass and mole fractions for a mixture ever the same?

Generally not. If the components all had the same molecular mass the mass and mole fractions would be the same.

11.b

For a mixture how many component concentrations are needed?

A total of N-1 concentrations are needed, N equals total number of components, whether mass or mole fractions. They must sum up to one so the last one is by default.

11.c

Are any of the properties (P, T, v) for oxygen and nitrogen in air the same?

In any mixture under equilibrium T is the same for all components.
Each species has its own pressure equal to its partial pressure P_i.
The partial volume for a component is: $v_i = V/m_i$ and V is the same for all components so v_i is not.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.d

If I want to heat a flow of a 4 component mixture from 300 to 310 K at constant P, how many properties and which ones do I need to know to find the heat transfer?

You need to know the flow rate, the four mass fractions, and the component specific heat values (or the h values at both temperatures).

11.e

To evaluate the change in entropy between two states at different T and P values for a given mixture, do I need to find the partial pressures?

Not necessarily provided it is an ideal gas. If the mixture composition does not change then the mixture can be treated as a pure substance where each of the partial pressures is a constant fraction of the total pressure, Eq.11.10 and the changes in u, h and s can be evaluated with the mixture properties as in Eqs. 11.20-24.
If constant specific heat is an inappropriate model to use then u, h and a standard entropy must be evaluated from expressions as in Eqs.11.11-12 and 11.16, this is precisely what is done to make the air tables A.7 from the nitrogen, oxygen and argon properties.

If the substance is not an ideal gas mixture then the properties will depend on the partial pressures.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.f

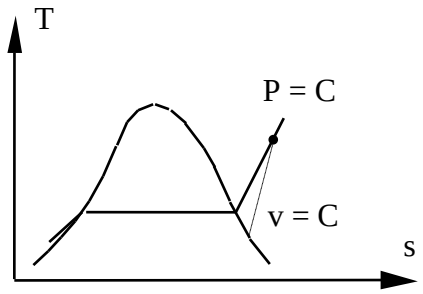
What happens to relative and absolute humidity when moist air is heated?

Relative humidity decreases, while absolute humidity remains constant.
See Figs. 11.8 and 11.9.

11.g

If I cool moist air, do I reach the dew first in a constant-P or constant-V process?

The constant-volume line is steeper than the constant-pressure line,
see Fig. 11.3. Saturation in the constant-P process is at a higher T.



11.h

What happens to relative and absolute humidity when moist air is cooled?

Relative humidity increase, while absolute humidity remains constant until we reach the dew point. See Figs. 11.8 and 11.9. If we cool below the dew point the relative humidity stays at 100% and the absolute humidity (humidity ratio) drops as water condenses to liquid (or freezes to solid) and drops out of the gas mixture.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.i

Explain in words what the absolute and relative humidity expresses?

Absolute humidity is the ratio of the mass of vapor to the mass of dry air. It says how much water is there per unit mass of dry air.
Relative humidity is the ratio of the mole fraction of vapor to that in a saturated mixture at the same T and P. It expresses how close to the saturated state the water is.

11.j

An adiabatic saturation process changes Φ, ω and T. In which direction?

Relative humidity and absolute humidity increase, and temperature decreases. Why does the temperature decrease? The energy to evaporate some liquid water to go into the gas mixture comes from the immediate surroundings to the liquid water surface where water evaporates, look at the dashed curve in Fig. 11.9. The moist air and the liquid water both cool down.

Concept-study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.1

Equal masses of argon and helium are mixed. Is the molecular mass of the mixture the linear average of the two individual ones?

No. The individual molecular masses must be combined using the mole fractions as in:

$$M_{mix} = \sum y_j M_j$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.2

A constant flow of pure argon and pure helium are mixed to produce a flow of mixture mole fractions 0.25 and 0.75 respectively. Explain how to meter the inlet flows to ensure the proper ratio assuming inlet pressures are equal to the total exit pressure and all temperatures are the same.

The inlet flow rate in terms of mass or moles is the same as the exit rate for each component in the mixture. Since the inlet P for each component is the same as the total exit P (which is the sum of the partial pressures if ideal gas) then the volume flow rates in and out are different for each species.

$$P \dot{V}_i = \dot{m}_i R_i T = \dot{n}_i \bar{R} T$$

$$P \dot{V}_{tot} = \dot{n}_{tot} \bar{R} T$$

We can therefore meter the volume flow rate $\dot{V}_i$ to be proportional to $\dot{n}_i$ for each line of the inlet flows. From these two equations we can get the ratio as

$$\dot{V}_i / \dot{V}_{tot} = \dot{n}_i / \dot{n}_{tot} = y_i$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.3

For a gas mixture in a tank are the partial pressures important?

Yes. The sum of the partial pressures equals the total pressure and if they are ideal gases the partial pressures are equal to the mole fraction times the total pressure so

$$P_i = y_i P \qquad \text{and} \qquad \sum P_i = \sum y_i P = P$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.4

An ideal mixture at T, P is made from ideal gases at T, P by charging them into a steel tank. Assume heat is transferred so T stays the same as the supply. How do the properties (P, v and u) for each component change up, down or constant?

Solution:

Ideal gas: u = u(T) so **constant**
P **drops** from P to partial P_i
v **increases** from v at P to v at P_i same T

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.5

An ideal mixture at T, P is made from ideal gases at T, P by flow into a mixing chamber without any external heat transfer and an exit at P. How do the properties (P, v and h) for each component change up, down or constant?

Solution:

Ideal gas: $h_{mix} = \sum (c_i h_i)_{out} = \sum (c_i h_i)_{in}$ same function of T

so **constant** T and then also **constant** h_i

P **drops** from P to partial P_i

v **increases** from v at P to v at P_i same T

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.6

If a certain mixture is used in a number of different processes do I need to consider partial pressures?

No. If the mixture composition stays the same, the pressure for each component, which is a partial pressure, is the same fraction of the total pressure, thus any variation follows the total pressure. Recall air is a mixture and we can deal with most processes involving air without knowledge about its composition. However, to make the air properties we do need to deal with the composition but only once.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.7

Why is it that I can use a set of tables for air, which is a mixture, without dealing with its composition?

As long as the composition is fixed any property is a fixed weighted average of the components properties and thus only varies with T and total P.

A process that will cool air to saturation and condensation can not be handled by the air tables. In such a process the composition of the liquid and vapor mixtures are different.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.8

Develop a formula to show how the mass fraction of water vapor is connected to the humidity ratio.

By definition the mass concentration is

$$c = \frac{m_v}{m_a + m_v} = \frac{m_v/m_a}{1 + m_v/m_a} = \frac{\omega}{1 + \omega}$$

and since ω is small then $1 + \omega \approx 1$ and c is close to ω (but not equal to).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.9

For air at 110^{o}C and 100 kPa is there any limit on the amount of water it can hold?

No. Since P_g = 143.3 kPa at 110^{o}C and P_v < 100 kPa ω can be infinity.

$$\omega = 0.622 \frac{P_v}{P_a} = 0.622 \frac{P_v}{P - P_v}$$

As P_v approaches P, w goes towards infinity.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.10

Can moist air below the freezing point, say -5^{o}C, have a dew point?

Yes. At the dew point, water would begin to appear as a solid. It snows. Since it is frost forming on surfaces rather than dew, you can call it frost point.

The contrails after the jets are tiny ice particles formed due to the very low (-40 C) temperature at high altitudes.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.11

Why does a car with an air-conditioner running often have water dripping out?

The cold evaporator that cools down an air flow brings it below the dew point temperature and thus condenses water out.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.12

Moist air at 35°C, $\omega = 0.0175$ and $\Phi = 50\%$ should be brought to a state of 20°C, $\omega = 0.01$ and $\Phi = 70\%$. Do I need to add or subtract water?

The humidity ratio (absolute humidity) expresses how much water vapor is present in the mixture

$$\omega = m_v / m_a$$

so to decrease ω we must **subtract water** from the mixture.
The relative humidity expresses how close to the saturated state the vapor is as

$$\Phi = P_v / P_g$$

and not about how much water there is.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Mixture composition and properties

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.13

If oxygen is 21% by mole of air, what is the oxygen state (P, T, v) in a room at 300 K, 100 kPa of total volume 60 m^3?

The temperature is 300 K,
The partial pressure is $P = yP_{tot} = 0.21 \times 100 = 21$ kPa.
At this T, P:

$$v_{O2} = RT/P_{O2} = 0.2598 \text{ kJ/kg-K} \times 300 \text{ K} / 21 \text{ kPa} = 3.711 \text{ m}^3/\text{kg}$$

Remark: If we found the oxygen mass then $m_{O2}v_{O2} = V = 60 \text{ m}^3$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.14

A 3 L liquid mixture is 1/3 of each of water, ammonia and ethanol by volume. Find the mass fractions and total mass of the mixture.

Each component has a partial volume of 1 L = 0.001 m^3

$m_{water} = V/v_f = 0.001\ m^3/ (0.001\ m^3/kg) = 1\ kg$
$m_{amm} = V/v_f = 0.001\ m^3 \times 604\ kg/m^3 = 0.604\ kg$
$m_{ethanol} = V/v_f = 0.001\ m^3 \times 783\ kg/m^3 = 0.783\ kg$

The v_f for water is from Table B.1.1 and $v_f = 1/\rho$ is from A.4

Total mass is: $m = 1 + 0.604 + 0.783 = 2.387\ kg$

$c_{water} = m_{water}/m = 1 / 2.387 = 0.419$
$c_{amm} = m_{amm}/m = 0.604 / 2.387 = 0.253$
$c_{ethanol} = m_{ethanol}/m = 0.783 /2.387 = 0.328$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.15

A flow of oxygen and one of nitrogen, both 300 K, are mixed to produce 1 kg/s air at 300 K, 100 kPa. What are the mass and volume flow rates of each line?

For the mixture, M = 0.21×32 + 0.79×28.013 = 28.85

For O_2 , c = 0.21 × 32 / 28.85 = 0.2329

For N_2 , c = 0.79 × 28.013 / 28.85 = 0.7671

Since the total flow out is 1 kg/s, these are the component flows in kg/s.
Volume flow of O_2 in is

$$\dot{V} = c\dot{m}\, v = c\dot{m}\, \frac{RT}{P} = 0.2329 \text{ kg/s}\, \frac{0.2598 \text{ kJ/kg-K} \times 300 \text{ K}}{100 \text{ kPa}} = \mathbf{0.1815\ m^3/s}$$

Volume flow of N_2 in is

$$\dot{V} = c\dot{m}\, v = c\dot{m}\, \frac{RT}{P} = 0.7671 \text{ kg/s}\, \frac{0.2968 \text{ kJ/kg-K} \times 300 \text{ K}}{100 \text{ kPa}} = \mathbf{0.6830\ m^3/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.16

A gas mixture at 20°C, 125 kPa is 50% N_2, 30% H_2O and 20% O_2 on a mole basis. Find the mass fractions, the mixture gas constant and the volume for 5 kg of mixture.

Solution:

The conversion follows the definitions and identities:

From Eq.11.3: $c_i = y_i M_i / \sum y_j M_j$

From Eq.11.5:

$$M_{mix} = \sum y_j M_j = 0.5 \times 28.013 + 0.3 \times 18.015 + 0.2 \times 31.999$$
$$= 14.0065 + 5.4045 + 6.3998 = 25.811$$

$c_{N2} = 14.0065 / 25.811 = 0.5427$, $c_{H2O} = 5.4045 / 25.811 = 0.2094$

$c_{O2} = 6.3998 / 25.811 = 0.2479$, sums to 1 OK

From Eq.11.14:

$R_{mix} = \bar{R}/M_{mix} = 8.3145$ kJ/kmol-K / 25.811 kg/kmol = **0.3221 kJ/kg K**

$V = mR_{mix} T/P = 5$ kg $\times 0.3221$ kJ/kg-K $\times 393.15$ K/125 kPa = **5.065 m^3**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.17

A mixture of 60% N_2, 30% Ar and 10% O_2 on a mass basis is in a cylinder at 250 kPa, 310 K and volume 0.5 m^3. Find the mole and the mass fractions and the mass of argon.

Solution:

Total mixture $PV = m R_{mix} T$

Mixture composition: c's for $(N_2, Ar, O_2) = (0.6, 0.3, 0.1)$

From Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.6 \times 0.2968 + 0.3 \times 0.2081 + 0.1 \times 0.2598$$
$$= 0.26629 \text{ kJ/kg K}$$

$$m = PV/R_{mix}T = \frac{250 \text{ kPa} \times 0.5 \text{ m}^3}{0.26649 \text{ kJ/kg-K} \times 310 \text{ K}} = 1.513 \text{ kg}$$

$m_{ar} = 0.3 \text{ m} = \mathbf{0.454 \text{ kg}}$

From Eq.11.4: $y_i = (c_i / M_i) / \sum c_j/M_j$

	c_i	M_i	c_i/M_i	$\mathbf{y_i}$	
N_2	0.6	28.013	0.02141	**0.668**	
Ar	0.3	39.948	0.00751	**0.234**	
O_2	0.1	31.999	0.003125	**0.098**	round up
			0.032055		

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.18

A slightly oxygenated air mixture is 69% N_2, 1% Ar and 30% O_2 on a mole basis. Assume a total pressure of 101 kPa and find the mass fraction of oxygen and its partial pressure.

Solution:

From Eq. 11.3: $c_i = y_i M_i / \sum y_j M_j$

Eq.11.5:

$M_{mix} = \sum y_j M_j = 0.69 \times 28.013 + 0.01 \times 39.948 + 0.3 \times 31.999 = 29.328$

$c_{N2} = (0.69 \times 28.013) / 29.328 = 0.659$

$c_{Ar} = (0.01 \times 39.948) / 29.328 = 0.014$

$c_{O2} = (0.3 \times 31.999) / 29.328 =$ **0.327**, sums to 1 OK

From Eq.11.10:

$$P_{O2} = y_{O2} P = 0.3 \times 101 = \mathbf{30.3\ kPa}$$

$R_{mix} = \bar{R}/M_{MIX} = 8.3145$ kJ/kmol-K / 29.328 kg/kmol = 0.2835 kJ/kg K

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.19

A new refrigerant R-407 is a mixture of 23% R-32, 25% R-125 and 52% R-134a on a mass basis. Find the mole fractions, the mixture gas constant and the mixture heat capacities for this new refrigerant.

Solution:

From the conversion in Eq.11.4 we get:

	c_i	M_i	c_i/M_i	y_i
R-32	0.23	52.024	0.004421	0.381
R-125	0.25	120.022	0.002083	0.180
R-134a	0.52	102.03	0.0050965	0.439
			0.0116005	

Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.23 \times 0.1598 + 0.25 \times 0.06927 + 0.52 \times 0.08149$$

$$= \mathbf{0.09645\ kJ/kg\ K}$$

Eq.11.23:

$$C_{P\,mix} = \sum c_i\, C_{P\,i} = 0.23 \times 0.822 + 0.25 \times 0.791 + 0.52 \times 0.852$$

$$= \mathbf{0.8298\ kJ/kg\ K}$$

Eq.11.21:

$$C_{v\,mix} = \sum c_i C_{v\,i} = 0.23 \times 0.662 + 0.25 \times 0.721 + 0.52 \times 0.771$$

$$= \mathbf{0.7334\ kJ/kg\ K}\ \ (= C_{P\,mix} - R_{mix})$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.20

In a car engine gasoline (assume octane C_8H_{18}) is evaporated and then mixed with air in a ratio of 1:15 by mass. In the cylinder the mixture is at 750 kPa, 650 K when the spark fires. For that time find the partial pressure of the octane and the specific volume of the mixture.

Assuming ideal gas the partial pressure is $P_i = y_i P$ and $c_{C8H18} = 1/16 = 0.0625$

From Eq. 11.4: $y_i = [c_i / M_i] / \sum c_j/M_j$

$$y_{C8H18} = \frac{0.0625/114.232}{0.0625/114.232 + 0.9375/28.97} = 0.008186$$

$$P_{C8H18} = 0.008186 \times 750 = \mathbf{6.14\ kPa}$$

The gas constant from Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.0625 \times 0.07279 + 0.9375 \times 0.287 = 0.27361\ \text{kJ/kg K}$$

$$v_{mix} = R_{mix} T/P = 0.27361 \times 650/750 = \mathbf{0.2371\ m^3/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.21

A 100 m^3 storage tank with fuel gases is at 20°C, 100 kPa containing a mixture of acetylene C_2H_2, propane C_3H_8 and butane C_4H_{10}. A test shows the partial pressure of the C_2H_2 is 15 kPa and that of C_3H_8 is 65 kPa. How much mass is there of each component?

Solution:

Assume ideal gases, then the ratio of partial to total pressure is the mole fraction, $y = P/P_{tot}$

$y_{C2H2} = 15/100 = 0.15$, $y_{C3H8} = 65/100 = 0.65$, $y_{C4H10} = 20/100 = 0.20$

$$n_{tot} = \frac{PV}{\bar{R}T} = \frac{100 \text{ kPa} \times 100 \text{ m}^3}{8.31451 \text{ kJ/kmol-K} \times 293.15 \text{ K}} = 4.1027 \text{ kmol}$$

$m_{C2H2} = (nM)_{C2H2} = y_{C2H2}\, n_{tot}\, M_{C2H2}$

$= 0.15 \times 4.1027 \text{ kmol} \times 26.038 \text{ kg/kmol} =$ **16.024 kg**

$m_{C3H8} = (nM)_{C3H8} = y_{C3H8}\, n_{tot}\, M_{C3H8}$

$= 0.65 \times 4.1027 \text{ kmol} \times 44.097 \text{ kg/kmol} =$ **117.597 kg**

$m_{C4H10} = (nM)_{C4H10} = y_{C4H10}\, n_{tot}\, M_{C4H10}$

$= 0.20 \times 4.1027 \text{ kmol} \times 58.124 \text{ kg/kmol} =$ **47.693 kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.22

A 2 kg mixture of 25% N_2, 50% O_2 and 25% CO_2 by mass is at 150 kPa and 300 K. Find the mixture gas constant and the total volume.

Solution:

From Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.25 \times 0.2968 + 0.5 \times 0.2598 + 0.25 \times 0.1889$$

$$= \mathbf{0.2513\ kJ/kg\ K}$$

Ideal gas law: $PV = mR_{mix}T$

$$V = mR_{mix}T/P = 2\ kg \times 0.2513\ kJ/kg\text{-}K \times 300\ K\ /150\ kPa = \mathbf{1.005\ m^3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.23

A diesel engine sprays fuel (assume n-Dodecane $C_{12}H_{26}$, M = 170.34 kg/kmol) into the combustion chamber so it becomes filled with an amount of 1 mol fuel per 88 mol air. Find the fuel fraction on a mass basis and the fuel mass for a chamber that is 0.5 L at 800 K and total pressure of 4000 kPa.

From Eq. 11.3: $c_i = y_i M_i / \sum y_j M_j$

$$c_{fuel} = \frac{(1/89) \times 170.34}{(1/89) \times 170.34 + (88/89)\, 28.97} = \mathbf{0.06263}$$

Use ideal gas for the fuel vapor

$$m_{fuel} = \frac{P_{fuel} V}{R_{fuel} T} = \frac{(1/89) \times 4000 \text{ kPa} \times 0.0005 \text{ m}^3}{(8.3145/170.34) \text{ kJ/kg-K} \times 800 \text{ K}} = \mathbf{0.575 \text{ g}}$$

We could also have done the total mass and then used the mass fraction

Eq.11.5: $M_{mix} = \sum y_j M_j = (1/89) \times 170.34 + (88/89) \times 28.97 = 30.558$

$R_{mix} = \bar{R}/M_{mix}$ b= 8.3145 / 30.558 = 0.27209

$m = PV / R_{mix} T = 4000 \times 0.0005 / (0.27209 \times 800) = 0.009188$ kg

$m_{fuel} = c_{fuel}\, m = 0.06263 \times 0.009188$ kg = 0.000575 kg = 0.575 g

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.24

A new refrigerant R-410A is a mixture of R-32 and R-125 in a 1:1 mass ratio. What are the overall molecular mass, the gas constant and the ratio of specific heats for such a mixture?

Eq.11.5:

$$M = \sum y_j M_j = 1 / \sum (c_j / M_j) = \frac{1}{\frac{0.5}{52.024} + \frac{0.5}{120.022}} = \mathbf{72.586}$$

Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.5 \times 0.1598 + 0.5 \times 0.06927 = \mathbf{0.1145\ kJ/kg\ K}$$

$$= \bar{R}/M_{MIX} = \frac{8.3145\ \text{kJ/kmol-K}}{72.586\ \text{kg/kmol}} = \text{same}\ \ (\text{from Eq.11.14})$$

Eq.11.23:

$$C_{P\ mix} = \sum c_i\ C_{P\ i} = 0.5 \times 0.822 + 0.5 \times 0.791 = 0.8065\ \text{kJ/kg K}$$

Eq.11.21:

$$C_{V\ mix} = \sum c_i C_{V\ i} = 0.5 \times 0.662 + 0.5 \times 0.722 = 0.692\ \text{kJ/kg K}$$

$$(= C_{P\ mix} - R_{mix})$$

$$k_{mix} = C_{P\ mix} / C_{V\ mix} = 0.8065 / 0.692 = \mathbf{1.1655}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.25

Do Problem 11.24 for R-507a which is 1:1 mass ratio of R-125 and R-143a. The refrigerant R-143a has molecular mass of 84.041 kg/kmol and C_p = 0.929 kJ/kg-K.

Refrigerant R-143a is not in Table A.5 so:

$$R = \bar{R}/M = 8.3145 \text{ kJ/kmol-K} / 84.041 \text{ kg/kmol} = 0.098934 \text{ kJ/kg-K}$$
$$C_V = C_p - R = 0.929 - 0.098934 = 0.8301 \text{ kJ/kg-K}$$

Eq.11.5:

$$M = \sum y_j M_j = = 1 / \sum (c_j / M_j) = \frac{1}{\frac{0.5}{120.022} + \frac{0.5}{84.041}} = \mathbf{98.859}$$

Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.5 \times 0.06927 + 0.5 \times 0.098934 = \mathbf{0.0841 \text{ kJ/kg K}}$$
$$= \bar{R}/M_{MIX} = \frac{8.3145 \text{ kJ/kmol-K}}{98.859 \text{ kg/kmol}} = \text{same} \quad \text{(this is from Eq.11.14)}$$

Eq.11.23:

$$C_{P\ mix} = \sum c_i\ C_{P\ i} = 0.5 \times 0.791 + 0.5 \times 0.929 = 0.86 \text{ kJ/kg K}$$

Eq.11.21:

$$C_{V\ mix} = \sum c_i C_{V\ i} = 0.5 \times 0.722 + 0.5 \times 0.8301 = 0.776 \text{ kJ/kg K}$$
$$(= C_{P\ mix} - R_{mix})$$

$$k_{mix} = C_{P\ mix} / C_{V\ mix} = 0.86 / 0.776 = \mathbf{1.108}$$

11.26

A rigid container has 1 kg CO_2 at 300 K and 1 kg argon at 400 K both at 150 kPa. Now they are allowed to mix without any heat transfer. What is final T, P?

No Q, No W so the energy equation gives constant U

Energy Eq.:

$$U_2 - U_1 = 0 = m_{CO2}(u_2 - u_1)_{CO2} + m_{Ar}(u_2 - u_1)_{Ar}$$

$$= m_{CO2}C_{v\,CO2}(T_2 - T_1)_{CO2} + m_{Ar}C_{v\,Ar}(T_2 - T_1)_{Ar}$$

$$= (1\times0.653 + 1\times0.312)\ \text{kJ/K} \times T_2 - (1\times0.653\times300 + 1\times0.312\times400)\ \text{kJ}$$

$$T_2 = \mathbf{332.3\ K},$$

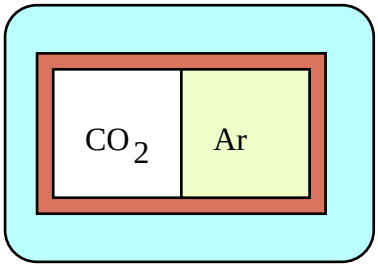
$$V = V_1 = V_{CO2} + V_{Ar} = m_{CO2}R_{CO2}T_{CO2}/P + m_{Ar}R_{Ar}T_{Ar}/P$$

$$= (1\times0.1889\times300 + 1\times0.2081\times400)\ \text{kJ} /150\ \text{kPa} = 0.932\ 73\ \text{m}^3$$

Pressure from ideal gas law and Eq.11.15 for R

$$mR = 1\ \text{kg} \times 0.1889\ \text{kJ/kg-K} + 1\ \text{kg} \times 0.2081\ \text{kJ/kg-K} = 0.397\ \text{kJ/K}$$

$$P_2 = mRT/V = 0.397\ \text{kJ/K} \times 332.3\ \text{K}/\ 0.932\ 73\ \text{m}^3 = \mathbf{141.4\ kPa}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.27

At a certain point in a coal gasification process, a sample of the gas is taken and stored in a 1-L cylinder. An analysis of the mixture yields the following results:

Component	H_2	CO	CO_2	N_2
Percent by mass	2	45	28	25

Determine the mole fractions and total mass in the cylinder at 100 kPa, 20°C. How much heat transfer must be transferred to heat the sample at constant volume from the initial state to 100°C?

Solution:

Determine mole fractions from Eq.11.4: $y_i = (c_i / M_i) / \sum c_j/M_j$

$$\sum c_j / M_j = 0.02 / 2.016 + 0.45 / 28.01 + 0.28 / 44.01 + 0.25 / 28.013$$
$$= 0.009921 + 0.016065 + 0.006362 + 0.00892 = 0.041268 \text{ kmol/kg}$$

$$M_{mix} = 1 / \sum c_j/M_j = 1/0.041268 = 24.232 \text{ kg/kmol}$$

From Eq.11.4

$y_{H2} = 0.009921 \times 24.232 = 0.2404$ $\quad y_{CO} = 0.016065 \times 24.232 = 0.3893$

$y_{CO2} = 0.006362 \times 24.232 = 0.1542$ $\quad y_{N2} = 0.00892 \times 24.232 = 0.2161$

$$R_{mix} = \bar{R}/M_{mix} = 8.3145 \text{ kJ/kmol-K} / 24.232 \text{ kg/kmol} = 0.34312 \text{ kJ/kg-K}$$

$$m = \frac{PV}{RT} = \frac{100 \text{ kPa} \times 10^{-3}\text{m}^3}{0.34312 \text{ kJ/kg-K} \times 293.15 \text{ K}} = \mathbf{9.942\times10^{-4}\ kg}$$

$$C_{V0\ MIX} = \sum c_i\, C_{V0\ i} = 0.02 \times 10.085 + 0.45 \times 0.744$$
$$+ 0.28 \times 0.653 + 0.25 \times 0.745 = 0.9056 \text{ kJ/kg K}$$

$$_1Q_2 = U_2 - U_1 = mC_{V0}(T_2-T_1)$$
$$= 9.942 \times 10^{-4} \text{ kg} \times 0.9056 \text{ kJ/kg-K} \times (100-20) \text{ K} = \mathbf{0.0720\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.28

The mixture in Problem 11.22 is heated to 500 K with constant volume. Find the final pressure and the total heat transfer needed using Table A.5.

Solution:

C.V. Mixture of constant volume.

Process: V = constant => $_1W_2 = \int P\, dV = 0$

Energy Eq.: $_1Q_2 = m(u_2 - u_1) \cong m\, C_{Vmix}\, (T_2 - T_1)$

Ideal gas: $PV = mRT$ => $P_2 = P_1(T_2 / T_1)(V_1/V_2)$

$P_2 = P_1T_2/T_1 = 150\ \text{kPa} \times 500/300 =$ **250 kPa**

From Eq.11.21:

$C_{Vmix} = \sum c_i C_{V\,i} = 0.25 \times 0.745 + 0.5 \times 0.662 + 0.25 \times 0.653$

$= 0.6805\ \text{kJ/kg K}$

$_1Q_2 = 2\ \text{kg} \times 0.6805\ \text{kJ/kg-K}\ (500 - 300)\ \text{K} =$ **272.2 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.29

The mixture in Problem 11.22 is heated up to 500 K in a constant pressure process. Find the final volume and the total heat transfer using Table A.5.

Solution:

C.V. Mixture

Process: P = constant => $_1W_2 = \int P\, dV = P(V_2 - V_1)$

Energy Eq.: $_1Q_2 = m(u_2 - u_1) + {}_1W_2 = m(u_2 - u_1) + Pm(v_2 - v_1)$

$= m(h_2 - h_1) \cong m\, C_{P\,mix}(T_2 - T_1)$

From Eq.11.15:

$R_{mix} = \sum c_i R_i = 0.25 \times 0.2968 + 0.5 \times 0.2598 + 0.25 \times 0.1889$

$= 0.2513$ kJ/kg K

From Eq.11.23:

$C_{P\,mix} = \sum c_i\, C_{P\,i} = 0.25 \times 1.042 + 0.5 \times 0.922 + 0.25 \times 0.842$

$= 0.932$ kJ/kg K

$V_2 = m\, R_{mix}\, T_2/P_2$

$= 2$ kg $\times$ 0.2513 kJ/kg-K $\times$ 500 K/150 kPa = **1.675 m^3**

$_1Q_2 = 2$ kg $\times$ 0.932 kJ/kg-K (500 – 300) K = **372.8 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.30

A flow of 1 kg/s argon at 300 K and another flow of 1 kg/s CO_2 at 1600 K both at 150 kPa are mixed without any heat transfer. What is the exit T, P?

No work implies no pressure change for a simple flow.

P_e = **150 kPa**

The energy equation becomes

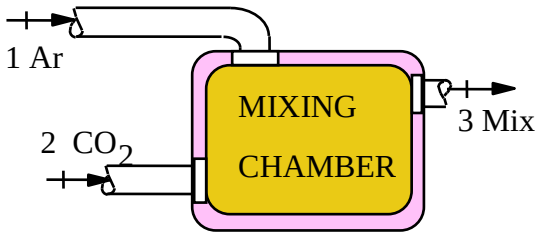
$$\dot{m}h_i = \dot{m}h_e = (\dot{m}h_i)_{Ar} + (\dot{m}h_i)_{CO2} = (\dot{m}h_e)_{Ar} + (\dot{m}h_e)_{CO2}$$

$$\Rightarrow \quad \dot{m}_{CO2}C_{p\,CO2}(T_e - T_i)_{CO2} + \dot{m}_{Ar}C_{p\,Ar}(T_e - T_i)_{Ar} = 0$$

$$\Rightarrow \quad \dot{m}_{Ar}C_{p\,Ar}T_i + \dot{m}_{CO2}C_{p\,CO2}T_i = [\dot{m}_{Ar}C_{p\,Ar} + \dot{m}_{CO2}C_{p\,CO2}]\,T_e$$

$$(1\times0.520\times300 + 1\times0.842\times1600)\ \text{kW} = (1\times0.520 + 1\times0.842)\ \text{kW/K} \times T_e$$

T_e = **1103.7 K**,



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.31

A flow of 1 kg/s argon at 300 K and another flow of 1 kg/s CO_2 at 1600 K both at 150 kPa are mixed without any heat transfer. Find the exit T, P using variable specific heats.

No work implies no pressure change for a simple flow.

P_e = **150 kPa**

The energy equation becomes

$$\dot{m}h_i = \dot{m}h_e = (\dot{m}h_i)_{Ar} + (\dot{m}h_i)_{CO2} = (\dot{m}h_e)_{Ar} + (\dot{m}h_e)_{CO2}$$

$$\Rightarrow \quad \dot{m}_{CO2}\,(h_e - h_i)_{CO2} + \dot{m}_{Ar} C_{p\,Ar}(T_e - T_i)_{Ar} = 0$$

$$\Rightarrow \quad 1\ \text{kg/s} \times (h_e - 1748.12\ \text{kJ/kg}) + (1 \times 0.52)\ \text{kW/K} \times (T_e - 300\ \text{K}) = 0$$

$$h_{e\,CO2} + 0.52\ T_e = 1748.12 + 0.52 \times 300 = 1904.12\ \text{kJ/kg}$$

Trial and error on T_e using Table A.8 for $h_{e\,CO2}$

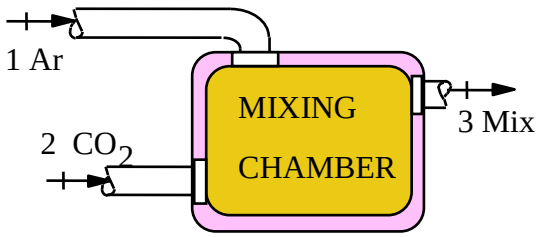
T_e = 1100 K: LHS = 1096.36 + 0.52 × 1100 = 1668.36 too small

T_e = 1300 K: LHS = 1352.28 + 0.52 × 1300 = 2028.28 too large

T_e = 1200 K: LHS = 1223.34 + 0.52 × 1200 = 1847.34 too small

Final interpolation

$$T_e = 1200 + 100\,\frac{1904.12 - 1847.34}{2028.28 - 1847.34} = \textbf{1231.4 K},$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.32

A pipe flows 0.1 kg/s of a mixture with mass fractions of 40% CO_2 and 60% N_2 at 400 kPa, 300 K. Heating tape is wrapped around a section of pipe with insulation added and 2 kW electrical power is heating the pipe flow. Find the mixture exit temperature.

Solution:

C.V. Pipe heating section. Assume no heat loss to the outside, ideal gases.

Energy Eq.: $\dot{Q} = \dot{m}(h_e - h_i) = \dot{m}C_{P\ mix}(T_e - T_i)$

From Eq.11.23

$$C_{P\ mix} = \sum c_i\, C_{P\ i} = 0.4 \times 0.842 + 0.6 \times 1.042 = 0.962 \text{ kJ/kg K}$$

Substitute into energy equation and solve for exit temperature

$$T_e = T_i + \dot{Q} / \dot{m}C_{P\ mix} = 300 + 2 \text{ kW}/ (0.1 \times 0.962) \text{ kW/K} = \mathbf{320.8\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.33

A steady flow of 0.1 kg/s carbon dioxide at 1000 K in one line is mixed with 0.2 kg/s of nitrogen at 400 K from another line, both at 100 kPa. The mixing chamber is insulated and has constant pressure of 100 kPa. Use constant heat capacity to find the mixing chamber exit temperature.

Take CV around the mixing chamber

Continuity Eq.4.9: $\dot{m}_1 + \dot{m}_2 = \dot{m}_3$;

Concentrations: $c_{CO_2} = \dot{m}_1/\dot{m}_3 = 1/3$; $c_{N_2} = \dot{m}_2/\dot{m}_3 = 2/3$

$$C_{P\,mix} = \sum c_i\, C_{P\,i} = (1/3) \times 0.842 + (2/3) \times 1.042 = 0.97533 \text{ kJ/kg}$$

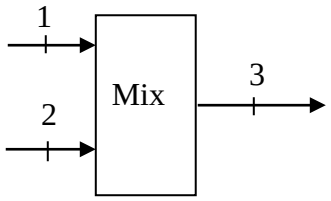
$$R_{mix} = \sum c_i R_i = (1/3) \times 0.1889 + (2/3) \times 0.2968 = 0.2608 \text{ kJ/kg}$$

Energy Eq.: $\dot{m}_1 h_1 + \dot{m}_2 h_2 = \dot{m}_3 h_3 = \dot{m}_1 h_{3\,CO_2} + \dot{m}_2 h_{3\,N_2}$

Divide this equation with $\dot{m}_3$ and take differences in h as $C_P\,\Delta T$

$$\frac{1}{3} C_{P\,CO_2} T_1 + \frac{2}{3} C_{P\,N_2} T_2 = [\frac{1}{3} C_{P\,CO_2} + \frac{2}{3} C_{P\,N_2}]\, T_3 = C_{P\,mix} T_3$$

$$T_3 = [\frac{1}{3} \times 0.842 \times 1000 + \frac{2}{3} \times 1.042 \times 400\ ] / 0.97533 = \mathbf{572.7\ K}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.34

An insulated gas turbine receives a mixture of 10% CO_2, 10% H_2O and 80% N_2 on a mass basis at 1000 K, 500 kPa. The volume flow rate is 2 m^3/s and its exhaust is at 700 K, 100 kPa. Find the power output in kW using constant specific heat from A.5 at 300 K.

Solution:

C.V. Turbine, Steady, 1 inlet, 1 exit flow with an ideal gas mixture, q = 0.

Energy Eq.: $\dot{W}_T = \dot{m}(h_i - h_e) = \dot{m}C_{P\,mix}(T_i - T_e)$

Properties: From Eqs.11.15 and 11.23

$$R_{mix} = \sum c_i R_i = 0.1 \times 0.1889 + 0.1 \times 0.4615 + 0.8 \times 0.2968$$
$$= 0.30248 \text{ kJ/kg K}$$

$$C_{P\,mix} = \sum c_i\, C_{P\,i} = 0.1 \times 0.842 + 0.1 \times 1.872 + 0.8 \times 1.042$$
$$= 1.105 \text{ kJ/kg K}$$

$$PV = mR_{mix}T \quad => \quad \dot{m} = P\dot{V} / R_{mix}T$$

$$\dot{m} = 500 \text{ kPa} \times 2 \text{ m}^3/\text{s} /(0.30248 \times 1000) \text{ kJ/kg} = 3.306 \text{ kg/s}$$

$$\dot{W}_T = 3.306 \text{ kg/s} \times 1.105 \text{ kJ/kg-K } (1000 - 700) \text{ K} = \mathbf{1096\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.35

Solve Problem 11.34 using the values of enthalpy from Table A.8.
An insulated gas turbine receives a mixture of 10% CO_2, 10% H_2O and 80% N_2 on a mass basis at 1000 K, 500 kPa. The volume flow rate is 2 m^3/s and its exhaust is at 700 K, 100 kPa. Find the power output in kW using constant specific heat from A.5 at 300 K.

Solution:

C.V. Turbine, Steady, 1 inlet, 1 exit flow with an ideal gas mixture, q = 0.

Energy Eq.: $\dot{W}_T = \dot{m}(h_i - h_e) = \dot{m} \sum c_j (h_i - h_e)_j$

Properties: From Eqs.11.15 and 11.23

$$R_{mix} = \sum c_i R_i = 0.1 \times 0.1889 + 0.1 \times 0.4615 + 0.8 \times 0.2968$$
$$= 0.30248 \text{ kJ/kg K}$$

$$PV = mR_{mix}T \quad => \quad \dot{m} = P\dot{V} / R_{mix}T$$

$$\dot{m} = 500 \text{ kPa} \times 2 \text{ m}^3/\text{s} / (0.30248 \times 1000) \text{ kJ/kg} = 3.306 \text{ kg/s}$$

Now get the h values from Table A.8 (all in kJ/kg)

$$\dot{W}_T = 3.306 \text{ kg/s} [\ 0.1 (971.67 - 616.22) + 0.1 (1994.13 - 1338.56)$$
$$+ 0.8 (1075.91 - 735.86)\ ] \text{ kJ/kg}$$
$$= \mathbf{1234\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.36

Solve Problem 11.33 assuming the flows are in kmol/s.
A steady flow of 0.1 kg/s carbon dioxide at 1000 K in one line is mixed with 0.2 kg/s of nitrogen at 400 K from another line, both at 100 kPa. The mixing chamber is insulated and has constant pressure of 100 kPa. Use constant heat capacity to find the mixing chamber exit temperature.

Take CV around the mixing chamber

Continuity Eq. mole basis: $\dot{n}_1 + \dot{n}_2 = \dot{n}_3$;

Concentrations: $y_{CO_2} = \dot{n}_1/\dot{n}_3 = 1/3$; $y_{N_2} = \dot{n}_2/\dot{n}_3 = 2/3$

$$\bar{C}_{P\,mix} = \sum y_i \bar{C}_{P\,i} = \frac{1}{3} \times 0.842 \times 44.01 + \frac{2}{3} \times 1.042 \times 28.013 = 31.81 \frac{kJ}{kmol}$$

$$M_{mix} = \sum y_i M_i = (1/3) \times 44.01 + (2/3) \times 28.013 = 33.345 \text{ kg/kmol}$$

Energy Eq. Mole basis: $\dot{n}_1 h_1 + \dot{n}_2 \bar{h}_2 = \dot{n}_3 \bar{h}_3 = \dot{n}_1 \bar{h}_{3\,CO_2} + \dot{n}_2 \bar{h}_{3\,N_2}$

Divide this equation with $\dot{n}_3$ and take differences in $\bar{h}$ as $\bar{C}_P \Delta T$

$$\frac{1}{3} \bar{C}_{P\,CO_2} T_1 + \frac{2}{3} \bar{C}_{P\,N_2} T_2 = [\frac{1}{3} \bar{C}_{P\,CO_2} + \frac{2}{3} \bar{C}_{P\,N_2}]\, T_3 = \bar{C}_{P\,mix}\, T_3$$

$$T_3 = [\frac{1}{3} \times 37.056 \times 1000 + \frac{2}{3} \times 29.189 \times 400\ ] / 31.81 = \mathbf{633\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.37

Solve Problem 11.34 with the percentages on a mole basis and use Table A.9. An insulated gas turbine receives a mixture of 10% CO_2, 10% H_2O and 80% N_2 on a mole basis at 1000 K, 500 kPa. The volume flow rate is 2 m^3/s and its exhaust is at 700 K, 100 kPa. Find the power output in kW using constant specific heat from A.5 at 300 K.

C.V. Turbine, Steady flow, 1 inlet, 1 exit flow with an ideal gas mixture, and no heat transfer so q = 0.

Energy Eq.: $\dot{W}_T = \dot{m}\,(h_i - h_e) = \dot{n}\,(\bar{h}_i - \bar{h}_e) = \dot{n}\,[\,\sum y_j\,(\bar{h}_i - \bar{h}_e)_j\,]$

Ideal gas law: $PV = n\bar{R}T$ =>

$$\dot{n} = \frac{P\dot{V}}{\bar{R}T} = \frac{500\ \text{kPa} \times 2\ \text{m}^3/\text{s}}{8.3145\ \text{kJ/kmol-K} \times 1000\ \text{K}} = 0.1203\ \text{kmol/s}$$

Read the enthalpies from Table A.9 (they are all in kJ/kmol)

$$\dot{W}_T = 0.1203[0.1(33397 - 17754) + 0.1(26000 - 14190) + 0.8(21463 - 11937)]$$

$$= \mathbf{1247\ kW}$$

11.38

A mixture of 0.5 kg nitrogen and 0.5 kg oxygen is at 100 kPa, 300 K in a piston cylinder keeping constant pressure. Now 800 kJ is added by heating. Find the final temperature and the increase in entropy of the mixture using Table A.5 values.

Solution:

C.V. Mixture in the piston cylinder.

Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Process: P = constant => ${}_1W_2 = \int P\, dV = P\,(V_2 - V_1)$

${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = m(u_2 - u_1) + mP(v_2 - v_1) = m(h_2 - h_1)$

$h_2 - h_1 = {}_1Q_2/m \cong C_{P\,mix}\,(T_2 - T_1)$

From Eq.11.23 and Table A.5:

$C_{P\,mix} = (1/2) \times 0.922 + (1/2) \times 1.042 = 0.982$ kJ/kg K

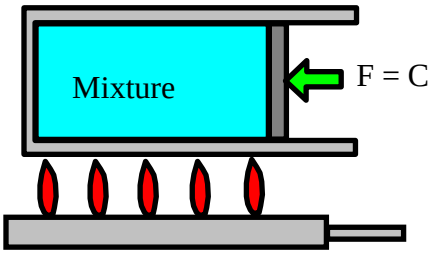
$T_2 = T_1 + {}_1Q_2/mC_{P\,mix}$

$= 300$ K + 800 kJ/(1 × 0.982) kJ/K = **1114.7 K**

From Eq.11.24:

$m(s_2 - s_1) = m[C_{P\,mix} \ln(T_2 / T_1) - R \ln(P_2 / P_1)]$

$= 1$ kg × 0.982 kJ/kg-K × ln (1114.7/300) = **1.29 kJ/K**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.39

A rigid insulated vessel contains 12 kg of oxygen at 200 kPa, 280 K separated by a membrane from 26 kg carbon dioxide at 400 kPa, 360 K. The membrane is removed and the mixture comes to a uniform state. Find the final temperature and pressure of the mixture.

Solution:

C.V. Total vessel. Control mass with two different initial states.

Mass: $m = m_{O2} + m_{CO2} = 12 + 26 = 38$ kg

Process: V = constant (rigid) => W = 0, insulated => Q = 0

Energy: $U_2 - U_1 = 0 - 0 = m_{O2} C_{V\,O2}(T_2 - T_{1\,O2}) + m_{CO2}C_{V\,CO2}(T_2 - T_{1\,CO2})$

Initial state from ideal gas Table A.5

$C_{V\,O2} = 0.662$ kJ/kg, $C_{V\,CO2} = 0.653$ kJ/kg K

O_2 : $V_{O2} = mRT_1/P = 12 \times 0.2598 \times 280/200 = 4.3646\ m^3$,

CO_2 : $V_{CO2} = mRT_1/P = 26 \times 0.1889 \times 360/400 = 4.4203\ m^3$

Final state mixture

$$R_{mix} = \sum c_i R_i = [12 \times 0.2598 + 26 \times 0.1889\ ]/38 = 0.2113 \text{ kJ/kg K}$$

The energy equation becomes

$$m_{O2} C_{V\,O2} T_2 + m_{CO2}C_{V\,CO2} T_2 = m_{O2} C_{V\,O2} T_{1\,O2} + m_{CO2}C_{V\,CO2} T_{1\,CO2}$$

$$(7.944 + 16.978)\ \text{kJ/K} \times T_2 = 2224.32 + 6112.08 = 8336.4\ \text{kJ}$$

$$\Rightarrow T_2 = \mathbf{334.5\ K}$$

From mixture gas constant and total volume

$$V_2 = V_{O2} + V_{CO2} = 4.3646\ m^3 + 4.4203\ m^3 = 8.7849\ m^3$$

$$P_2 = mR_{mix}T_2/V_2 = 38 \text{ kg} \times 0.2113 \text{ kJ/kg-K} \times 334.5 \text{ K}/ 8.7849\ m^3$$

$$= \mathbf{305.7\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.40

A mixture of 0.5 kg nitrogen and 0.5 kg oxygen is at 100 kPa, 300 K in a piston cylinder keeping constant pressure. Now 1200 kJ is added by heating. Find the final temperature and the increase in entropy of the mixture using Table A.8 values.

Solution:

C.V. Mixture in the piston cylinder.

Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Process: P = constant => ${}_1W_2 = \int P\, dV = P\,(V_2 - V_1)$

${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = m(u_2 - u_1) + mP(v_2 - v_1)$

$= m(h_2 - h_1)$

$h_2 - h_1 = {}_1Q_2/m = 1200$ kJ /1 kg = 1200 kJ/kg

Since T_2 is high we use Table A.8 values guessing a T_2

$$(h_2 - h_1)_{1400K} = \frac{1}{2}(1556.87 - 311.67) + \frac{1}{2}(1426.44 - 273.15)$$

$$= 1199.245 \text{ kJ/kg} \qquad \text{low}$$

$$(h_2 - h_1)_{1500K} = \frac{1}{2}(1680.70 - 311.67) + \frac{1}{2}(1540.23 - 273.15)$$

$$= 1318.06 \text{ kJ/kg} \qquad \text{too high}$$

$T_2 = 1400 + 100[(1200 - 1199.245)/(1318.06 - 1199.245)] =$ **1400.6 K**

From Eqs.11.16 and 11.18:

$$s_2 - s_1 = \frac{1}{2}(s^\circ_{T2} - s^\circ_{T1})_{N2} + \frac{1}{2}(s^\circ_{T2} - s^\circ_{T1})_{O2}$$

$$= \frac{1}{2}(8.5495 - 6.8463) + \frac{1}{2}(7.9869 - 6.4168)$$

$$= \mathbf{1.6367\ kJ/kg\ K}$$

Notice that the pressure term drop out, composition does not change and total pressure is constant.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.41

New refrigerant R-410A is a mixture of R-32 and R-125 in a 1:1 mass ratio. A process brings 0.5 kg R-410A from 270 K to 320 K at a constant pressure 250 kPa in a piston cylinder. Find the work and heat transfer.

Solution:

C.V. R-410A

Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2 = {}_1Q_2 - P\,(V_2 - V_1)$

Process: P = constant ${}_1W_2 = P\,(V_2 - V_1) = mR(T_2 - T_1)$

$${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = m(h_2 - h_1)$$

From Eq.11.15:

$$R_{mix} = \sum c_i R_i = \frac{1}{2} \times 0.1598 + \frac{1}{2} \times 0.06927 = 0.1145 \text{ kJ/kg K}$$

FromEq.11.23:

$$C_{P\,mix} = \frac{1}{2} \times 0.822 + \frac{1}{2} \times 0.791 = 0.8065 \text{ kJ/kg K}$$

From the process equation

${}_1W_2 = 0.5 \text{ kg} \times 0.1145 \text{ kJ/kg-K } (320 - 270) \text{ K} =$ **2.863 kJ**

From the energy equation

${}_1Q_2 = m\,C_{P\,mix}\,(T_2 - T_1) = 0.5 \text{ kg} \times 0.8065 \text{ kJ/kg-K } (320 - 270) \text{ K}$

= **20.16 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.42

A piston/cylinder device contains 0.1 kg of a mixture of 40 % methane and 60 % propane gases by mass at 300 K and 100 kPa. The gas is now slowly compressed in an isothermal (T = constant) process to a final pressure of 250 kPa. Show the process in a P-V diagram and find both the work and heat transfer in the process.

Solution:

C.V. Mixture of methane and propane, this is a control mass.

Assume methane & propane are ideal gases at these conditions.

Energy Eq.3.5: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Property from Eq.11.15

$$R_{mix} = 0.4\, R_{CH4} + 0.6\, R_{C3H8}$$

$$= 0.4 \times 0.5183 + 0.6 \times 0.1886 = 0.3205 \text{ kJ/kg K}$$

Process: T = constant & ideal gas =>

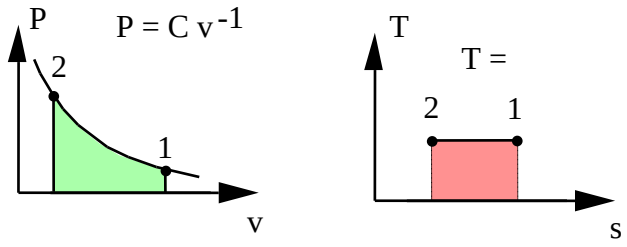
$${}_1W_2 = \int P\, dV = mR_{mix}T \int (1/V)dV = mR_{mix}T \ln (V_2/V_1)$$

$$= mR_{mix}T \ln (P_1/P_2)$$

$$= 0.1 \text{ kg} \times 0.3205 \text{ kJ/kg-K} \times 300 \text{ K} \ln (100/250) = \mathbf{-8.81\ kJ}$$

Now heat transfer from the energy equation where we notice that u is a constant (ideal gas and constant T) so

$${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = {}_1W_2 = \mathbf{-8.81\ kJ}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.43

The substance R-410A, see Problem 11.41 is at 100 kPa, 290 K. It is now brought to 250 kPa, 400 K in a reversible polytropic process. Find the change in specific volume, specific enthalpy and specific entropy for the process.

Solution:

Eq.11.15: $R_{mix} = \Sigma\, c_i R_i = \frac{1}{2} \times 0.1598 + \frac{1}{2} \times 0.06927 = 0.1145$ kJ/kg K

Eq.11.23: $C_{Pmix} = \Sigma\, c_i C_{Pi} = \frac{1}{2} \times 0.822 + \frac{1}{2} \times 0.791 = 0.8065$ kJ/kg K

$v_1 = RT_1/P_1 = 0.1145 \times 290/100 = 0.33205$ m^3/kg

$v_2 = RT_2/P_2 = 0.1145 \times 400/250 = 0.1832$ m^3/kg

$v_2 - v_1 = 0.1832 - 0.33205 =$ **-0.14885 m^3/kg**

$h_2 - h_1 = C_{Pmix}\,(T_2 - T_1) = 0.8065$ kJ/kg-K (400 – 290) K = **88.72 kJ/kg**

From Eq.11.24

$s_2 - s_1 = C_{Pmix} \ln(T_2 / T_1) - R_{mix} \ln(P_2 / P_1)$

$= 0.8065 \ln (400/290) - 0.1145 \ln (250/100) =$ **0.154 kJ/kg K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.44

Natural gas as a mixture of 75% methane and 25% ethane by mass is flowing to a compressor at 17°C, 100 kPa. The reversible adiabatic compressor brings the flow to 350 kPa. Find the exit temperature and the needed work per kg flow.

Solution:

C.V. Compressor. Steady, adiabatic q = 0, reversible $s_{gen} = 0$

Energy Eq.4.13: $-w = h_{ex} - h_{in}$; Entropy Eq.7.8: $s_i + s_{gen} = s_e$

Process: reversible => $s_{gen} = 0$ => $s_e = s_i$

Assume ideal gas mixture and constant heat capacity, so we need k and C_P

From Eq.11.15 and 11.23:

$$R_{mix} = \sum c_i R_i = 0.75 \times 0.5183 + 0.25 \times 0.2765 = 0.45785 \text{ kJ/kg K}$$

$$C_{P\,mix} = \sum c_i C_{Pi} = 0.75 \times 2.254 + 0.25 \times 1.766 = 2.132 \text{ kJ/kg K}$$

$$C_V = C_{P\,mix} - R_{mix} = 2.132 - 0.45785 = 1.6742 \text{ kJ/kg K}$$

Ratio of specific heats: $k = C_p / C_v = 1.2734$

The isentropic process gives Eq.6.23, from Eq.11.24 with $s_e = s_i$

$$T_e = T_i (P_e / P_i)^{(k-1)/k} = 290\ (350/100)^{0.2147} = \mathbf{379.5\ K}$$

Work from the energy equation:

$$w_{c\,in} = C_P (T_e - T_i) = 2.132 \text{ kJ/kg-K } (379.5 - 290) \text{ K} = \mathbf{190.8\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.45

A compressor brings R-410A (see problem 11.41) from –10 ^{o}C, 125 kPa up to 500 kPa in an adiabatic reversible compression. Assume ideal gas behavior and find the exit temperature and the specific work.

Solution:

C.V. Compressor

Process: $q = 0$; adiabatic and reversible.

Energy Eq.4.13: $w = h_i - h_e$;

Entropy Eq.7.8: $s_e = s_i + s_{gen} + \int dq/T = s_i + 0 + 0 = s_i$

From Eq.11.15:

$$R_{mix} = \sum c_i R_i = \frac{1}{2} \times 0.1598 + \frac{1}{2} \times 0.06927 = 0.1145 \text{ kJ/kg K}$$

FromEq.11.23:

$$C_{P\,mix} = \frac{1}{2} \times 0.822 + \frac{1}{2} \times 0.791 = 0.8065 \text{ kJ/kg K}$$

$$R_{mix}/ C_{P\,mix} = 0.1145/0.8065 = 0.14197$$

For constant s, ideal gas and use constant specific heat as in Eq.6.23

$$T_e/T_i = (P_e/P_i)^{R/Cp}$$

$$T_e = 263.15 \text{ K} \times (500/125)^{0.14197} = \mathbf{320.39\ K}$$

$$w \cong C_{P\,mix}(T_i - T_e) = 0.8065 \text{ kJ/kg-K } (263.15 – 320.39) \text{ K}$$

$$= \mathbf{-46.164\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.46

Two insulated tanks A and B are connected by a valve. Tank A has a volume of 1 m^3 and initially contains argon at 300 kPa, 10°C. Tank B has a volume of 2 m^3 and initially contains ethane at 200 kPa, 50°C. The valve is opened and remains open until the resulting gas mixture comes to a uniform state. Determine the final pressure and temperature.

Solution:

C.V. Tanks A + B. Control mass no W, no Q.

Energy Eq.3.5 and 3.36:

$$U_2 - U_1 = 0 = m_{Ar} C_{V0} (T_2 - T_{A1}) + m_{C_2H_6} C_{VO} (T_2 - T_{B1})$$

$$m_{Ar} = P_{A1} V_A / RT_{A1} = (300 \times 1) / (0.2081 \times 283.15) = 5.0913 \text{ kg}$$

$$m_{C_2H_6} = P_{B1} V_B / RT_{B1} = (200 \times 2) / (0.2765 \times 323.15) = 4.4767 \text{ kg}$$

Continuity Eq.: $m_2 = m_{Ar} + m_{C_2H_6} = 9.568$ kg

Energy Eq.: $5.0913 \times 0.312 \, (T_2 - 283.2)$

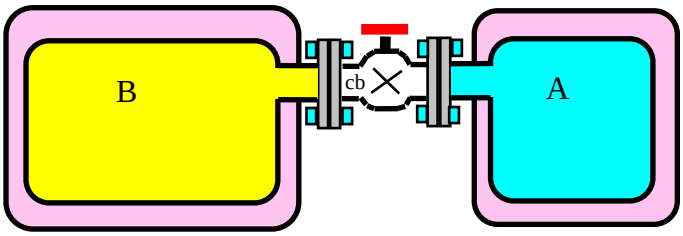
$$+ 4.4767 \times 1.490 \, (T_2 - 323.2) = 0$$

Solving, T_2 = **315.5 K**

$$R_{mix} = \Sigma \, c_i R_i = \frac{5.0913}{9.568} \times 0.2081 + \frac{4.4767}{9.568} \times 0.2765 = 0.2401 \text{ kJ/kg K}$$

$$P_2 = m_2 RT_2 / (V_A + V_B) = 9.568 \text{ kg} \times 0.2401 \text{ kJ/kg-K} \times 315.5 \text{ K} / 3 \text{ m}^3$$

= **242 kPa**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.47

A steady flow of 0.1 kmol/s carbon dioxide at 1000 K in one line is mixed with 0.2 kmol/s of nitrogen at 400 K from another line, both at 100 kPa. The exit mixture at 100 kPa is compressed by a reversible adiabatic compressor to 500 kPa. Use constant specific heat to find the mixing chamber exit temperature and the needed compressor power.

Take CV around the mixing chamber

Continuity Eq. mole basis: $\dot{n}_1 + \dot{n}_2 = \dot{n}_3$;

Concentrations: $y_{CO_2} = \dot{n}_1/\dot{n}_3 = 1/3$; $y_{N_2} = \dot{n}_2/\dot{n}_3 = 2/3$

$$\bar{C}_{P\,mix} = \sum y_i \bar{C}_{P\,i} = \frac{1}{3}\times 0.842 \times 44.01 + \frac{2}{3}\times 1.042 \times 28.013 = 31.81 \frac{kJ}{kmol}$$

$$R_{mix}/C_{P\,mix} = \bar{R}/\bar{C}_{P\,mix} = 8.3145 / 31.81 = 0.2614$$

Energy Eq. Mole basis: $\dot{n}_1 h_1 + \dot{n}_2 \bar{h}_2 = \dot{n}_3 \bar{h}_3 = \dot{n}_1 \bar{h}_{3\,CO_2} + \dot{n}_2 \bar{h}_{3\,N_2}$

Divide this equation with $\dot{n}_3$ and take differences in $\bar{h}$ as $\bar{C}_P\,\Delta T$

$$\frac{1}{3}\bar{C}_{P\,CO_2} T_1 + \frac{2}{3}\bar{C}_{P\,N_2} T_2 = [\frac{1}{3}\bar{C}_{P\,CO_2} + \frac{2}{3}\bar{C}_{P\,N_2}]\, T_3 = \bar{C}_{P\,mix}\, T_3$$

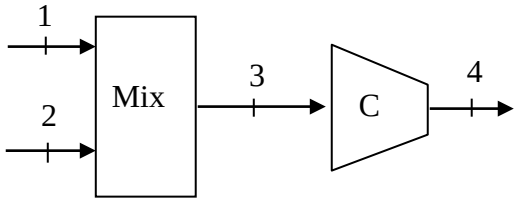
$$T_3 = [\frac{1}{3} \times 37.056 \times 1000 + \frac{2}{3} \times 29.189 \times 400\ ] / 31.81 = \mathbf{633\ K}$$

Now we can do the adiabatic compression

$$T_4 = T_3\,(P_4 / P_3)^{R/Cp} = 633 \times 5^{0.2614} = 964.1\ K$$

$$\bar{w}_C = \bar{C}_{P\,mix}\,(T_4 - T_3) = 31.81\ kJ/kmol\text{-}K\ (964.1 - 633)\ K$$
$$= 10\,532\ kJ/kmol$$

$$\dot{W} = \dot{m}\,\bar{w}_C = 0.3\ kmol/s \times 10\,532\ kJ/kmol = \mathbf{3160\ kW}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.48

A mixture of 2 kg oxygen and 2 kg of argon is in an insulated piston cylinder arrangement at 100 kPa, 300 K. The piston now compresses the mixture to half its initial volume. Find the final pressure, temperature and the piston work.

Solution:

C.V. Mixture. Control mass, boundary work and no Q, assume reversible.

Energy Eq.3.5: $u_2 - u_1 = {}_1q_2 - {}_1w_2 = - {}_1w_2$;

Entropy Eq.6.37: $s_2 - s_1 = 0 + 0 = 0$

Process: constant s => Pv^k = constant, $v_2 = v_1/2$,

Assume ideal gases ($T_1 >> T_C$) and use k_{mix} and $C_{v\,mix}$ for properties.

Eq.11.15: $R_{mix} = \Sigma\, c_i R_i = 0.5 \times 0.25983 + 0.5 \times 0.20813 = 0.234$ kJ/kg K

Eq.11.23 $C_{Pmix} = \Sigma\, c_i C_{Pi} = 0.5 \times 0.9216 + 0.5 \times 0.5203 = 0.721$ kJ/kg K

$C_{vmix} = C_{Pmix} - R_{mix} = 0.487$ kJ/kg K

Ratio of specific heats: $k_{mix} = C_{Pmix}/C_{vmix} = 1.4805$

The relations for the polytropic process

Eq.6.25: $P_2 = P_1(v_1/v_2)^k = P_1(2)^k = 100(2)^{1.4805} =$ **279 kPa**

Eq.6.24: $T_2 = T_1(v_1/v_2)^{k-1} = T_1(2)^{k-1} = 300(2)^{0.4805} =$ **418.6 K**

Work from the energy equation

${}_1W_2 = m_{tot}\,(u_1 - u_2) = m_{tot}\,C_v(T_1 - T_2)$

$= 4$ kg $\times 0.487$ kJ/kg-K (300 - 418.6) K = **-231 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.49

The gas mixture from Problem 11.27 is compressed in a reversible adiabatic process from the initial state in the sample cylinder to a volume of 0.2 L. Determine the final temperature of the mixture and the work done during the process.

Solution:

From Eq.11.15

$$R_{mix} = \sum c_i R_i = 0.02 \times 4.1243 + 0.45 \times 0.2968 + 0.28 \times 0.1889 + 0.25 \times 0.2968 = 0.34314 \text{ kJ/kg K}$$

$$m = PV/R_{mix}T = 100\times10^{-3}/(0.34314\times 293.15) = \mathbf{9.941\times10^{-4}\ kg}$$

$$C_{V0\ MIX} = \sum c_i\, C_{V0\ i} = 0.02 \times 10.085 + 0.45 \times 0.744 + 0.28 \times 0.653 + 0.25 \times 0.745 = 0.9056 \text{ kJ/kg K}$$

$$C_{P0\ MIX} = C_{V0\ MIX} + R_{mix} = 0.9056 + 0.34314 = 1.2487 \text{ kJ/kg K}$$

$$\rightarrow k = C_{P0}/C_{V0} = 1.2487/0.9056 = 1.379$$

The process (adiabatic and reversible) is isentropic expressed in Eq.6.32

$$\rightarrow T_2 = T_1\left(\frac{V_1}{V_2}\right)^{k-1} = 293.15\left(\frac{1}{0.2}\right)^{0.379} = \mathbf{539.5\ K}$$

$${}_1W_2 = -\Delta U_{12} = -mC_{V0}(T_2-T_1)$$

$$= -\ 9.941\times10^{-4}\ \text{kg} \times 0.9056\ \text{kJ/kg-K} \times (539.5 - 293.15)\ \text{K} = \mathbf{-\ 0.22\ kJ}$$

11.50

A piston cylinder has 0.1 kg mixture of 25% argon, 25% nitrogen and 50% carbon dioxide by mass at total pressure 100 kPa and 290 K. Now the piston compresses the gases to a volume 7 times smaller in a polytropic process with n = 1.3. Find the final pressure and temperature, the work, and the heat transfer for the process.

Solution:

Expansion ratio: $v_2/ v_1 = 1/7$

Mixture properties:

$$R_{mix} = \Sigma\, c_i R_i = 0.25 \times 0.2081 + 0.25 \times 0.2968 + 0.5 \times 0.1889$$
$$= 0.220675 \text{ kJ/kg K}$$

$$C_{v\,mix} = \sum c_i\, C_{vi} = 0.25 \times 0.312 + 0.25 \times 0.745 + 0.5 \times 0.653$$
$$= 0.59075 \text{ kJ/kg K}$$

Process eq.: Rev. adiabatic and ideal gas gives $Pv^n = C$, with n = 1.3

$$P_2 = P_1 (v_1/v_2)^n = 100 \times 7^{1.3} = \mathbf{1254.9\ kPa}$$

$$T_2 = T_1 (v_1/v_2)^{n-1} = 290 \times 7^{0.3} = \mathbf{519.9\ K}$$

Polytropic process work term from Eq.3.21 and ideal gas law

$$_1W_2 = \frac{mR}{1 - n}(T_2 - T_1) = \frac{0.1 \times 0.220675}{-0.3} \text{ kJ/K } (519.9 - 290) \text{ K} = \mathbf{-16.91\ kJ}$$

Energy Eq.: $_1Q_2 = U_2 - U_1 + {}_1W_2 = m\, C_{v\,mix} (T_2 - T_1) + {}_1W_2$

$$= 0.1 \text{ kg} \times 0.59075 \text{ kJ/kg-K } (519.9 - 290) \text{ K} - 16.91 \text{ kJ}$$
$$= \mathbf{-3.33\ kJ}$$

Entropy generation

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.51

A flow of gas A and a flow of gas B are mixed in a 1:2 mole ratio with the same T. What is the entropy generation per kmole flow out?

For this case the total flow is 3 mol units so,

$$y_A = n_A/n_{tot} = 1/3; \qquad y_B = n_B/n_{tot} = 2/3$$

Eq. 11.19: $\Delta S = - \bar{R}[\, (1/3) \ln 1/3 + (2/3) \ln 2/3 \,] = + 0.6365\, \bar{R}$

$= \mathbf{5.292\ kJ/kmol\ K}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.52

A rigid container has 1 kg argon at 300 K and 1 kg argon at 400 K both at 150 kPa. Now they are allowed to mix without any external heat transfer. What is final T, P? Is any s generated?

Energy Eq.: $U_2 - U_1 = 0 = 2mu_2 - mu_{1a} - mu_{1b} = mC_v(2T_2 - T_{1a} - T_{1b})$

$$T_2 = (T_{1a} + T_{1b})/2 = \mathbf{350\ K},$$

Process Eq.: V = constant =>

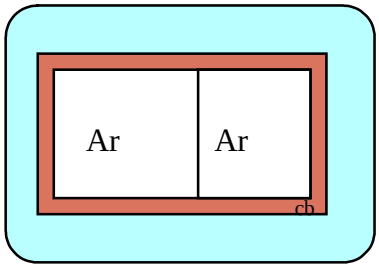
$$P_2V = 2mRT_2 = mR(T_{1a} + T_{1b}) = P_1V_{1a} + P_1V_{1b} = P_1V$$

$$P_2 = P_1 = \mathbf{150\ kPa},$$

ΔS due to temperature changes only, not P, internally we have a Q over a ΔT

$$\Delta S = m(s_2 - s_{1a}) + m(s_2 - s_{1b}) = mC_p[\ln(T_2/T_{1a}) + \ln(T_2/T_{1b})]$$

$$= 1\ \text{kg} \times 0.520\ \text{kJ/kg-K}\left[\ln\frac{350}{300} + \ln\frac{350}{400}\right] = \mathbf{0.0107\ kJ/K}$$



Why did we not account for partial pressures? Since we mix argon with argon there is no entropy generation due to mixing and no partial pressure.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.53

What is the entropy generation in problem 11.26?

No Q, No W so the energy equation gives constant U

Energy Eq.: $U_2 - U_1 = 0 = m_{CO2}(u_2 - u_1)_{CO2} + m_{Ar}(u_2 - u_1)_{Ar}$

$= m_{CO2}C_{v\,CO2}(T_2 - T_1)_{CO2} + m_{Ar}C_{v\,Ar}(T_2 - T_1)_{Ar}$

$= (1\times0.653 + 1\times0.312) \times T_2 - 1\times0.653\times300 - 1\times0.312\times400$

$T_2 =$ **332.3 K**,

$V = V_1 = V_{CO2} + V_{Ar} = m_{CO2}R_{CO2}T_{CO2}/P + m_{Ar}R_{Ar}T_{Ar}/P$

$= 1\times0.1889\times300/150 + 1\times0.2081\times400/150 = 0.932\ 73\ m^3$

Pressure from ideal gas law and Eq.11.15 for R

$P_2 = (1\times0.1889 + 1\times0.2081) \times 332.3/0.932\ 73 =$ **141.4 kPa**

$S_2 - S_1 = 0 + {}_1S_{2\,gen} = m_{CO2}(s_2 - s_1)_{CO2} + m_{Ar}(s_2 - s_1)_{Ar}$

For each component: $s_2 - s_1 = C_P \ln \frac{T_2}{T_1} - R \ln \frac{yP_2}{P_1}$ [P's are total pressure]

$$y_{CO2} = \frac{c_{CO2}/M_{CO2}}{c_{CO2}/M_{CO2} + c_{Ar}/M_{Ar}} = \frac{0.5 / 44.01}{0.5 / 39.948 + 0.5 / 44.01} = 0.4758$$

$y_{Ar} = 1 - y_{CO2} = 0.5242$

$${}_1S_{2\,gen} = 1\ \text{kg} \times [0.520 \ln(\frac{332.3}{400}) - 0.2081 \ln (\frac{0.5242 \times 141.4}{150})]\ \text{kJ/kg-K}$$

$$+ 1\ \text{kg} \times [0.842 \ln(\frac{332.3}{300}) - 0.1889 \ln (\frac{0.4758 \times 141.4}{150})]\ \text{kJ/kg-K}$$

$= 0.05027 + 0.23756 =$ **0.2878 kJ/K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.54

A flow of 2 kg/s mixture of 50% CO_2 and 50% O_2 by mass is heated in a constant pressure heat exchanger from 400 K to 1000 K by a radiation source at 1400 K. Find the rate of heat transfer and the entropy generation in the process shown in Fig. P11.54.

Solution:

C.V. Heat exchanger w = 0

Energy Eq.4.12: $\dot{Q}_{in} = \dot{m}(h_e - h_i)$

Values from Table A.8 due to the high T.

$$\dot{Q}_{in} = 2\,[\tfrac{1}{2} \times (971.67 - 303.76) + \tfrac{1}{2} \times (980.95 - 366.03)] = \mathbf{1282.8\ kW}$$

Entropy Eq.7.8: $\dot{m}_e s_e = \dot{m}_i s_i + \dot{Q}/T_s + \dot{S}_{gen}$

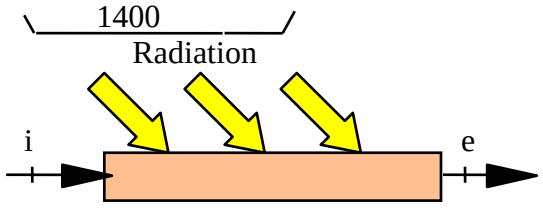
As the pressure is constant the pressure correction in Eq.6.19 drops out to give the generation as

$$\dot{S}_{gen} = \dot{m}(s_e - s_i) - \dot{Q}/T_s$$

$$= 2\ \text{kg/s}\ [\tfrac{1}{2} \times (6.119 - 5.1196) + \tfrac{1}{2} \times (7.6121 - 6.6838)]\ \text{kJ/kg-K}$$

$$- 1282.8\ \text{kW}\ /1400\ \text{K}$$

$$= \mathbf{1.01\ kW/K}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.55

A flow of 1.8 kg/s steam at 400 kPa, 400°C is mixed with 3.2 kg/s oxygen at 400 kPa, 400 K in a steady flow mixing-chamber without any heat transfer. Find the exit temperature and the rate of entropy generation.

C.V. Mixing chamber, steady flow, no work, no heat transfer. To do the entropies we need the mole fractions.

$$\dot{n}_{H2O} = \frac{\dot{m}_{H2O}}{M_{H2O}} = \frac{1.8}{18.015} = 0.1 \text{ kmol/s}; \quad \dot{n}_{O2} = \frac{\dot{m}_{O2}}{M_{O2}} = \frac{3.2}{31.999} = 0.1 \text{ kmol/s}$$

$$y_{H2O} = y_{O2} = 0.5$$

Energy Eq.: $\dot{m}_{H2O}\, h_1 + \dot{m}_{O2}\, h_2 = \dot{m}_{H2O}\, h_{3\,H2O} + \dot{m}_{O2}\, h_{3\,O2}$

Entropy Eq.: $\dot{m}_{H2O}\, s_1 + \dot{m}_{O2}\, s_2 + \dot{S}_{gen} = \dot{m}_{H2O}\, s_{3\,H2O} + \dot{m}_{O2}\, s_{3\,O2}$

Solve for T from the energy equation

$$\dot{m}_{H2O}\,(h_{3\,H2O} - h_1) + \dot{m}_{O2}\,(h_{3\,O2} - h_2) = 0$$

$$\dot{m}_{H2O}\, C_{P\,H2O}(T_3 - T_1) + \dot{m}_{O2}\, C_{P\,O2}(T_3 - T_2) = 0$$

$$1.8 \times 1.872\,(T_3 - 400 - 273.15) + 3.2 \times 0.922(T_3 - 400) = 0$$

$$T_3 = \mathbf{545.6\ K}$$

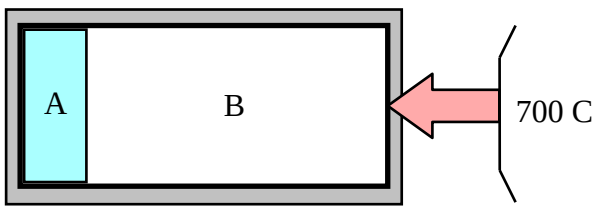
$$\dot{S}_{gen} = \dot{m}_{H2O}\,(s_{3\,H2O} - s_1) + \dot{m}_{O2}\,(s_{3\,O2} - s_2)$$

$$= \dot{m}_{H2O}\left[\, C_{P\,H2O} \ln \frac{T_3}{T_1} - R \ln y_{H2O} \,\right] + \dot{m}_{O2}\left[\, C_{P\,O2} \ln \frac{T_3}{T_2} - R \ln y_{O2} \,\right]$$

$$= 1.8 \text{ kg/s}\left[\, 1.872 \ln \frac{545.6}{673.15} - 0.4615 \ln 0.5 \,\right] \text{kJ/kg-K}$$

$$+ 3.2 \text{ kg/s}\left[\, 0.922 \ln \frac{545.6}{400} - 0.2598 \ln 0.5 \,\right] \text{kJ/kg-K}$$

$$= -0.132 + 1.492 = \mathbf{1.36\ kW/K}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.56

Carbon dioxide gas at 320 K is mixed with nitrogen at 280 K in an insulated mixing chamber. Both flows are at 100 kPa and the mass ratio of carbon dioxide to nitrogen is 2:1. Find the exit temperature and the total entropy generation per kg of the exit mixture.

Solution:

CV mixing chamber. The inlet ratio is so $\dot{m}_{CO_2} = 2\,\dot{m}_{N_2}$ and assume no external heat transfer, no work involved.

Continuity Eq.6.9: $\dot{m}_{N_2} + 2\dot{m}_{N_2} = \dot{m}_{ex} = 3\dot{m}_{N_2}$;

Energy Eq.6.10: $\dot{m}_{N_2}(h_{N_2} + 2\,h_{CO_2}) = 3\dot{m}_{N_2} h_{mix\ ex}$

Take 300 K as reference and write $h = h_{300} + C_{Pmix}(T - 300)$.

$$C_{P\,N_2}(T_{i\,N_2} - 300) + 2C_{P\,CO_2}(T_{i\,CO_2} - 300) = 3C_{P\,mix}(T_{mix\ ex} - 300)$$

$$C_{P\,mix} = \sum c_i C_{P\,i} = \frac{2}{3} \times 0.842 + \frac{1}{3} \times 1.042 = 0.9087 \text{ kJ/kg K}$$

$$3C_{P\,mix}T_{mix\ ex} = C_{P\,N_2}T_{i\,N_2} + 2C_{P\,CO_2}T_{i\,CO_2} = 830.64 \text{ kJ/kg}$$

$T_{mix\ ex}$ = **304.7 K**;

To find the entropies we need the partial pressures, which assuming ideal gas are equal to the mole fractions times the total pressure:

$$y_i = [c_i / M_i] / \sum c_j/M_j$$

$$y_{N_2} = [0.3333 / 28.013] / [\frac{0.3333}{28.013} + \frac{0.6666}{44.01}] = 0.44$$

$$y_{CO_2} = 1 - y_{N_2} = 0.56$$

$$\dot{S}_{gen} = \dot{m}_{ex}s_{ex} - (\dot{m}s)_{iCO_2} - (\dot{m}s)_{iN_2} = \dot{m}_{N_2}(s_e - s_i)_{N_2} + 2\dot{m}_{N_2}(s_e - s_i)_{CO_2}$$

$$\frac{\dot{S}_{gen}}{3\dot{m}_{N_2}} = \frac{1}{3}[C_{PN_2}\ln\frac{T_{ex}}{T_{iN_2}} - R_{N_2}\ln y_{N_2}] + \frac{2}{3}[C_{PCO_2}\ln\frac{T_{ex}}{T_{iCO_2}} - R_{CO_2}\ln y_{CO_2}]$$

$$= \frac{1}{3}[\,1.042\ln(\frac{304.7}{280}) - 0.2968\ln 0.44\,] + \frac{2}{3}[\,0.842\ln(\frac{304.7}{320}) - 0.1889\ln 0.56\,]$$

$$= 0.110585 + 0.068275 = \textbf{0.1789 kJ/kg mix K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.57

Carbon dioxide gas at 320 K is mixed with nitrogen at 280 K in an insulated mixing chamber. Both flows are coming in at 100 kPa and the mole ratio of carbon dioxide to nitrogen is 2:1. Find the exit temperature and the total entropy generation per kmole of the exit mixture.

CV mixing chamber, steady flow. The inlet ratio is $\dot{n}_{CO_2} = 2\,\dot{n}_{N_2}$ and assume no external heat transfer, no work involved.

Continuity: $\dot{n}_{CO_2} + 2\dot{n}_{N_2} = \dot{n}_{ex} = 3\dot{n}_{N_2}$;

Energy Eq.: $\dot{n}_{N_2}(\bar{h}_{N_2} + 2\bar{h}_{CO_2}) = 3\dot{n}_{N_2}\bar{h}_{mix\ ex}$

Take 300 K as reference and write $\bar{h} = \bar{h}_{300} + \bar{C}_{Pmix}(T - 300)$.

$$\bar{C}_{P\,N_2}(T_{i\,N_2} - 300) + 2\bar{C}_{P\,CO_2}(T_{i\,CO_2} - 300) = 3\bar{C}_{P\,mix}(T_{mix\ ex} - 300)$$

Find the specific heats in Table A.5 to get

$$\bar{C}_{P\,mix} = \sum y_i \bar{C}_{P\,i} = (1.042 \times 28.013 + 2 \times 0.842 \times 44.01)/3$$
$$= 34.43\ \text{kJ/kmol K}$$

$$3\bar{C}_{P\,mix}T_{mix\ ex} = \bar{C}_{P\,N_2}T_{i\,N_2} + 2\bar{C}_{P\,CO_2}T_{i\,CO_2} = 31889\ \text{kJ/kmol}$$

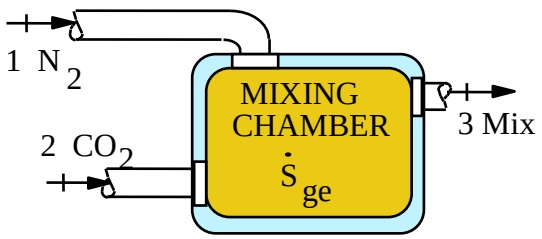
$$T_{mix\ ex} = \mathbf{308.7\ K}$$

Partial pressures are total pressure times molefraction

$$P_{ex\,N_2} = P_{tot}/3; \quad P_{ex\,CO_2} = 2P_{tot}/3$$

$$\dot{S}_{gen} = \dot{n}_{ex}\bar{s}_{ex} - (\dot{n}\bar{s})_{iCO_2} - (\dot{n}\bar{s})_{iN_2} = \dot{n}_{N_2}(\bar{s}_e - \bar{s}_i)_{N_2} + 2\dot{n}_{N_2}(\bar{s}_e - \bar{s}_i)_{CO_2}$$

$$\dot{S}_{gen}/3\dot{n}_{N_2} = [\bar{C}_{PN_2}\ln\frac{T_{ex}}{T_{iN_2}} - \bar{R}\ln y_{N_2} + 2\bar{C}_{PCO_2}\ln\frac{T_{ex}}{T_{iCO_2}} - 2\,\bar{R}\ln y_{CO_2}]/3$$
$$= [2.8485 + 9.1343 - 2.6607 + 6.742]/3 = \mathbf{5.35\ kJ/kmol\ mix\ K}$$

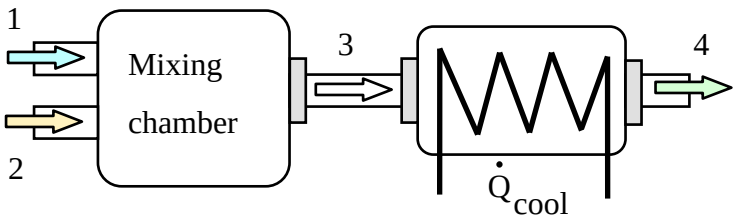


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.58

A flow of 1 kg/s carbon dioxide at 1600 K, 100 kPa is mixed with a flow of 2 kg/s water at 800 K, 100 kPa and after the mixing it goes through a heat exchanger where it is cooled to 500 K by a 400 K ambient. How much heat transfer is taken out in the heat exchanger? What is the entropy generation rate for the whole process?

Solution:



C.V. Total mixing section and heat exchanger. Steady flow and no work. To do the entropy at the partial pressures we need the mole fractions.

$$\dot{n}_{H2O} = \dot{m}_{H2O}/M_{H2O} = 2 / 18.015 = 0.11102 \text{ kmol/s}$$

$$\dot{n}_{CO2} = \dot{m}_{CO2}/M_{CO2} = 1 / 44.01 = 0.022722 \text{ kmol/s}$$

$$y_{H2O} = \frac{0.11102}{0.11102 + 0.022722} = 0.8301, \quad y_{CO2} = 1 - y_{H2O} = 0.1699$$

Energy Eq.: $\dot{m}_{H2O}\, h_1 + \dot{m}_{CO2}\, h_2 = \dot{Q}_{cool} + \dot{m}_{H2O}\, h_{4\,H2O} + \dot{m}_{CO2}\, h_{4\,CO2}$

Entropy Eq.: $\dot{m}_{H2O}\, s_1 + \dot{m}_{CO2}\, s_2 + \dot{S}_{gen} = \dfrac{\dot{Q}_{cool}}{T_{amb}} + \dot{m}_{H2O}\, s_{4\,H2O} + \dot{m}_{CO2}\, s_{4\,CO2}$

As T is fairly high we use Table A.8 for properties on a mass basis.

	1	2	4 H2O	4 CO2
h [kJ/kg]	1550.13	1748.12	935.12	401.52
s^o_T [kJ/kg K]	12.4244	6.7254	11.4644	5.3375

$$\dot{Q}_{cool} = \dot{m}_{H2O}\,(h_1 - h_{4\,H2O}) + \dot{m}_{CO2}\,(h_2 - h_{4\,CO2})$$
$$= 2\,(1550.13 - 935.12) + 1\,(1748.12 - 401.52) = \mathbf{2577\ kW}$$

$$\dot{S}_{gen} = \dot{m}_{H2O}\,(s_{4\,H2O} - s_1) + \dot{m}_{CO2}\,(s_{4\,CO2} - s_2) + \dot{Q}_{cool}/T_{amb}$$
$$= 2 \text{ kg/s } [11.4644 - 12.4244 - 0.4615 \ln(0.8301)] \text{ kJ/kg-K}$$
$$+ 1 \text{ kg/s } [5.3375 - 6.7254 - 0.1889 \ln(0.1699)] \text{ kJ/kg-K} + \frac{2577}{400} \text{ kW/K}$$
$$= -1.74813 - 1.05307 + 6.4415 = \mathbf{3.64\ kW/K}$$

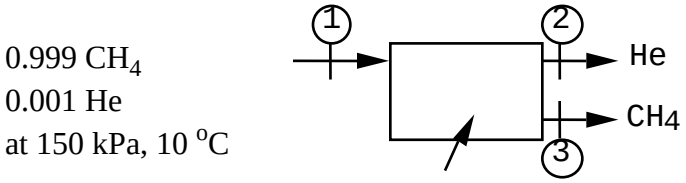
11.59

The only known sources of helium are the atmosphere (mole fraction approximately 5×10^{-6}) and natural gas. A large unit is being constructed to separate 100 m^3/s of natural gas, assumed to be 0.001 He mole fraction and 0.999 CH_4. The gas enters the unit at 150 kPa, 10°C. Pure helium exits at 100 kPa, 20°C, and pure methane exits at 150 kPa, 30°C. Any heat transfer is with the surroundings at 20°C. Is an electrical power input of 3000 kW sufficient to drive this unit?



0.999 CH_4
0.001 He
at 150 kPa, 10 °C
$\dot{V}_1 = 100\ m^3/s$

$P_2 = 100$ kPa
$T_2 = 20$ °C

$P_3 = 140$ kPa
$T_3 = 30$ °C

$-\dot{W}_{CV} = 3000$ kW

$\dot{n}_1 = P_1\dot{V}_1/RT_1 = 150\ kPa \times 100\ m^3/s\ /(8.3145 \times 283.2)\ kJ/kmol = 6.37\ kmol/s$

$\Rightarrow \quad \dot{n}_2 = 0.001; \quad \dot{n}_1 = 0.006\ 37; \quad \dot{n}_3 = 6.3636\ kmol/s$

$\bar{C}_{P\,He} = 4.003\ kg/kmol \times 5.193 kJ/kg\text{-}K = 20.7876\ kJ/kmol\ K,$

$\bar{C}_{P\,CH_4} = 16.043\ kg/kmol \times 2.254\ kJ/kg\text{-}K = 36.1609\ kJ/kmol\ K$

Energy Eq.:

$$\dot{Q}_{CV} = \dot{n}_2\bar{h}_2 + \dot{n}_3\bar{h}_3 - \dot{n}_1\bar{h}_1 + \dot{W}_{CV} = \dot{n}_2\bar{C}_{P0\,He}(T_2\text{-}T_1) + \dot{n}_3\bar{C}_{P0\,CH_4}(T_3\text{-}T_1) + \dot{W}_{CV}$$

$$= 0.00637 \times 20.7876(20 - 10) + 6.3636 \times 36.1609(30 - 10) + (-3000)$$

$$= +1600\ kW$$

Entropy Eq.:

$$\dot{S}_{gen} = \dot{n}_2\bar{s}_2 + \dot{n}_3\bar{s}_3 - \dot{n}_1\bar{s}_1 - \dot{Q}_{CV}/T_0$$

$$= 0.00637\left[20.7876 \ln\frac{293.2}{283.2} - 8.3145 \ln\frac{100}{0.001 \times 150}\right]$$

$$+ 6.3636\left[36.1609 \ln\frac{303.2}{283.2} - 8.3145 \ln\frac{140}{0.999 \times 150}\right] - 1600/293.2$$

$$= \mathbf{+13.5\ kW/K > 0}$$ Since positive, this is possible

11.60

Repeat Problem 11.44 for an isentropic compressor efficiency of 82%.

Solution:

C.V. Compressor. Steady, adiabatic q = 0, reversible $s_{gen} = 0$

Energy Eq.4.13: $-w = h_{ex} - h_{in}$; Entropy Eq.7.8: $s_i + s_{gen} = s_i = s_e$

Process: reversible => $s_{gen} = 0$ => $s_e = s_i$

Assume ideal gas mixture and constant heat capacity, so we need k and C_P

From Eq.11.15 and 11.23:

$R_{mix} = \sum c_i R_i = 0.75 \times 0.5183 + 0.25 \times 0.2765 = 0.45785$ kJ/kg K

$C_{P\,mix} = \sum c_i C_{Pi} = 0.75 \times 2.254 + 0.25 \times 1.766 = 2.132$ kJ/kg K

$C_V = C_{P\,mix} - R_{mix} = 2.132 - 0.45785 = 1.6742$ kJ/kg K

Ratio of specific heats: $k = C_p / C_v = 1.2734$

The isentropic process gives Eq.6.23, from Eq.11.24 with $s_e = s_i$

$T_e = T_i (P_e / P_i)^{(k-1)/k} = 290\ (350/100)^{0.2147} =$ **379.5 K**

Isentropic work from the energy equation:

$w_{c\,in} = C_P (T_e - T_i) = 2.132$ kJ/kg-K (379.5 – 290) K = 190.8 kJ/kg

The actual compressor requires more work

$w_{c\,actual} = w_{c\,in}/\eta = 190.8/0.82 =$ **232.7 kJ/kg** $= C_p (T_{e\,actual} - T_i)$

$T_{e\,actual} = T_i + w_{c\,actual}/C_P$

= 290 K + 232.7 kJ/kg / 2.132 kJ/kg-K = **399.1 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.61

A steady flow 0.3 kg/s of 60% carbon dioxide and 40% water mixture by mass at 1200 K and 200 kPa is used in a constant pressure heat exchanger where 300 kW is extracted from the flow. Find the exit temperature and rate of change in entropy using Table A.5

Solution:

C.V. Heat exchanger, Steady, 1 inlet, 1 exit, no work.

Continuity Eq.: $c_{CO2} = c_{H2O} = 0.5$

Energy Eq.: $\dot{Q} = \dot{m}(h_e - h_i) \approx \dot{m}\, C_P\, (T_e - T_i)$ => $T_e = T_i + \dot{Q}/\dot{m}\, C_P$

Inlet state: Table A.5

$$C_P = 0.6 \times 0.842 + 0.4 \times 1.872 = 1.254 \text{ kJ/kg-K}$$

Exit state: $T_e = T_i + \dot{Q}/\dot{m}\, C_P = 1200 \text{ K} - 300 \text{ kW}/(0.3 \times 1.254 \text{ kW/K})$

$$= \mathbf{402.6\ K}$$

The rate of change of entropy for the flow is (P is assumed constant)

$$\dot{m}(s_e - s_i) = \dot{m}[s^o_{Te} - s^o_{Ti} - R \ln(P_e/P_i)] = \dot{m}[s^o_{Te} - s^o_{Ti}) \approx \dot{m}\, C_P \ln(T_e/T_i)$$

$$= 0.3 \times 1.254 \ln(402.6 / 1200) = \mathbf{-0.411\ kW/K}$$

The entropy generation rate cannot be estimated unless the average T at which the heat transfer leaves the control volume is known.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.62

A steady flow of 0.3 kg/s of 60% carbon dioxide and 40% water by mass at 1200 K and 200 kPa is used in a heat exchanger where 300 kW is extracted from the flow. Find the flow exit temperature and the rate of change of entropy using Table A.8.

Solution:

C.V. Heat exchanger, Steady, 1 inlet, 1 exit, no work.

Continuity Eq.: $c_{CO2} = 0.6, \quad c_{H2O} = 0.4$

Energy Eq.: $\dot{Q} = \dot{m}(h_e - h_i) \quad => \quad h_e = h_i + \dot{Q}/\dot{m}$

Inlet state: Table A.8 $\quad h_i = 0.6 \times 1223.34 + 0.4 \times 2466.25 = 1720.5$ kJ/kg

Exit state: $h_e = h_i + \dot{Q}/\dot{m} = 1720.5 - 300/0.3 = 720.5$ kJ/kg

Trial and error for T with h values from Table A.8

@500 K $\quad h_e = 0.6 \times 401.52 + 0.4 \times 935.12 = 614.96$ kJ/kg

@600 K $\quad h_e = 0.6 \times 506.07 + 0.4 \times 1133.67 = 757.11$ kJ/kg

@550 K $\quad h_e = 0.6 \times 453.03 + 0.4 \times 1033.63 = 685.27$ kJ/kg

Interpolate to have the right h: **T = 575 K**

Entropy Eq.7.8: $\dot{m}s_e = \dot{m}s_i + \dot{Q}/T + \dot{S}_{gen}$

The rate of change of entropy for the flow is (P is assumed constant)

$$\dot{m}(s_e - s_i) = \dot{m}(s^o_{Te} - s^o_{Ti})$$

$$= 0.3[\ 0.6(5.48175 - 6.3483) + 0.4(11.73925 - 13.3492)\ ]$$

$$= \mathbf{-0.349\ kW/K}$$

The entropy generation rate cannot be estimated unless the integral dQ/T can be evaluated. If the dQ leaves at the local mixture T (assumed uniform over the flow cross section) the process is internally reversible and then externally irreversible.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.63

A mixture of 60% helium and 40% nitrogen by mass enters a turbine at 1 MPa, 800 K at a rate of 2 kg/s. The adiabatic turbine has an exit pressure of 100 kPa and an isentropic efficiency of 85%. Find the turbine work.

Solution:

Assume ideal gas mixture and take CV as turbine.

Energy Eq.4.13: $w_{T\,s} = h_i - h_{es}$,

Entropy Eq.7.8: $s_{es} = s_i$, adiabatic and reversible

Process Eq.6.23: $T_{es} = T_i(P_e/P_i)^{(k-1)/k}$

Properties from Eq.11.23, 11.15 and 6.23

$C_{P\,mix} = 0.6\times 5.193 + 0.4\times 1.042 = 3.5326$ kJ/kg-K

$R_{mix} = 0.6\times 2.0771 + 0.4\times 0.2968 = 1.365$ kJ/kg-K

$(k-1)/k = R/C_{P\,mix} = 1.365/3.5326 = 0.3864$

$T_{es} = 800\text{ K}\,(100/1000)^{0.3864} = 328.6$ K

$w_{Ts} = C_P(T_i - T_{es}) = 3.5326$ kJ/kg-K $\times$ (800 - 328.6) K = 1665 kJ/kg

$w_{T\,ac} = \eta w_{Ts} = 0.85 \times 1665$ kJ/kg = 1415.5 kJ/kg

$\dot{W}_{T\,ac} = \dot{m} w_{T\,ac} = 2$ kg/s $\times$ 1415.5 kJ/kg = **2831 kW**

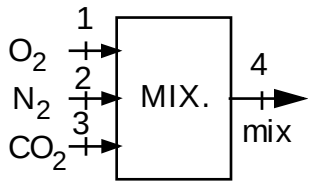
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.64

Three steady flows are mixed in an adiabatic chamber at 150 kPa. Flow one is 2 kg/s of O_2 at 340 K, flow two is 4 kg/s of N_2 at 280 K and flow three is 3 kg/s of CO_2 at 310 K. All flows are at 150 kPa the same as the total exit pressure. Find the exit temperature and the rate of entropy generation in the process.

Solution:

C.V. Mixing chamber, no heat transfer, no work.



Continuity Eq.4.9: $\dot{m}_1 + \dot{m}_2 + \dot{m}_3 = \dot{m}_4$

Energy Eq.4.10: $\dot{m}_1 h_1 + \dot{m}_2 h_2 + \dot{m}_3 h_3 = \dot{m}_4 h_4$

Entropy Eq.7.7: $\dot{m}_1 s_1 + \dot{m}_2 s_2 + \dot{m}_3 s_3 + \dot{S}_{gen} = \dot{m}_4 s_4$

Assume ideal gases and since T is close to 300 K use heat capacity from A.5 in the energy equation as

$$\dot{m}_1 C_{P\,O2}(T_1 - T_4) + \dot{m}_2 C_{P\,N2}(T_2 - T_4) + \dot{m}_3 C_{P\,CO2}(T_3 - T_4) = 0$$

$$(2 \times 0.922 \times 340 + 4 \times 1.042 \times 280 + 3 \times 0.842 \times 310)\ \text{kW}$$

$$= (2 \times 0.922 + 4 \times 1.042 + 3 \times 0.842)\ \text{kW/K} \times T_4$$

$$\Rightarrow \quad 2577.06\ \text{K} = 8.538\ T_4 \qquad \Rightarrow \quad \mathbf{T_4 = 301.83\ K}$$

State 4 is a mixture so the component exit pressure is the partial pressure. For each component $s_e - s_i = C_P \ln(T_e / T_i) - R \ln(P_e / P_i)$ and the pressure ratio is $P_e / P_i = y\, P_4 / P_i = y$ for each.

$$n = \sum \frac{m}{M} = \frac{2}{32} + \frac{4}{28.013} + \frac{3}{44.01} = 0.0625 + 0.1428 + 0.06817 = 0.2735$$

$$y_{O2} = \frac{0.0625}{0.2735} = 0.2285, \quad y_{N2} = \frac{0.1428}{0.2735} = 0.5222, \quad y_{CO2} = \frac{0.06817}{0.2735} = 0.2493$$

The entropy generation becomes

$$\dot{S}_{gen} = \dot{m}_1(s_4 - s_1) + \dot{m}_2(s_4 - s_2) + \dot{m}_3(s_4 - s_3)$$

$$= 2\,[\,0.922 \ln(301.83/340) - 0.2598 \ln(0.2285)]$$

$$+ 4\,[\,1.042 \ln(301.83/280) - 0.2968 \ln(0.5222)]$$

$$+ 3\,[\,0.842 \ln(301.83/310) - 0.1889 \ln(0.2493)]$$

$$= 0.5475 + 1.084 + 0.2399 = \mathbf{1.871\ kW/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.65

A tank has two sides initially separated by a diaphragm. Side A contains 1 kg of water and side B contains 1.2 kg of air, both at 20°C, 100 kPa. The diaphragm is now broken and the whole tank is heated to 600°C by a 700°C reservoir. Find the final total pressure, heat transfer and total entropy generation.

C.V. Total tank out to reservoir.

Energy Eq.3.5: $U_2 - U_1 = m_a(u_2 - u_1)_a + m_v(u_2 - u_1)_v = {}_1Q_2$

Entropy Eq.6.37:

$$S_2 - S_1 = m_a(s_2 - s_1)_a + m_v(s_2 - s_1)_v = {}_1Q_2/T_{res} + S_{gen}$$

Volume: $V_2 = V_A + V_B = m_v v_{v1} + m_a v_{a1} = 0.001 + 1.009 = 1.01\ m^3$

$v_{v2} = V_2/m_v = 1.01\ m^3/kg$, T_2 => $P_{2v} = 400$ kPa

$v_{a2} = V_2/m_a = 0.8417\ m^3/kg$, T_2 => $P_{2a} = mRT_2/V_2 = 297.7$ kPa

$P_{2tot} = P_{2v} + P_{2a} =$ **697.7 kPa**

Water table B.1: $u_1 = 83.95$ kJ/kg, $u_2 = 3300$ kJ/kg,

$s_1 = 0.2966$ kJ/kg K, $s_2 = 8.4558$ kJ/kg K

Air table A.7: $u_1 = 293$ kJ/kg, $u_2 = 652.3$ kJ/kg,

$s_{T1} = 2.492$ kJ/kg K, $s_{T2} = 3.628$ kJ/kg K

From energy equation we have

${}_1Q_2 = 1(3300 - 83.95) + 1.2(652.6 - 209.4) =$ **3747.9 kJ**

From the entropy equation we have

$S_{gen} = 1(8.4557 - 0.2966) + 1.2\ [7.9816 - 6.846 - 0.287 \times \ln(297.7/100)]$

$- 3747.9 / 973.2 =$ **5.3 kJ/K**

11.67

Atmospheric air is at 100 kPa, 25^{o}C and relative humidity 65%. Find the absolute humidity and the dew point of the mixture. If the mixture is heated to 30^{o}C what is the new relative humidity?

Solution:

Eq.11.25: $P_v = \phi P_g = 0.65 \times 3.169 = 2.06$ kPa

Eq.11.28: $w = 0.622\ P_v/(P_{tot} - P_v) = 0.622 \times 2.06/(100 - 2.06) =$ **0.01308**

T_{dew} is the T such that $P_g(T) = P_v = 2.06$ kPa

B.1.1 => $T_{dew} \cong$ **17.9 °C**

Heating => w is constant => P_v is constant

From Table B.1.1: $P_g(30°C) = 4.246$ kPa

$\phi = P_v/P_g = 2.06/4.246 =$ **0.485 or 49 %**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.68

A flow of 1 kg/s saturated moist air (relative humidity 100%) at 100 kPa, 10°C goes through a heat exchanger and comes out at 25°C. What is the exit relative humidity and how much power is needed?

Solution:

State 1 : $\phi_1 = 1$; $P_v = P_g = 1.2276$ kPa

Eq.11.28: $w = 0.622\ P_v/P_a = 0.622 \times 1.2276/(100 - 1.2276) = 0.00773$

State 2 : No water added => $w_2 = w_1$ => $P_{v2} = P_{v1}$

$\phi_2 = P_{v2}/P_{g2} = 1.2276/3.169 =$ **0.387 or 39 %**

Energy Eq.6.10

$$\dot{Q} = \dot{m}_2 h_2 - \dot{m}_1 h_1 = \dot{m}_a (h_2 - h_1)_{air} + w\dot{m}_a (h_2 - h_1)_{vapor}$$

$$\dot{m}_{tot} = \dot{m}_a + \dot{m}_v = \dot{m}_a (1 + w_1)$$

Energy equation with $C_{P\ air}$ from A.5 and h's from B.1.1

$$\dot{Q} = \frac{\dot{m}_{tot}}{1 + w_1} C_{P\ air} (25 - 10) + \frac{\dot{m}_{tot}}{1 + w_1} w (h_{g2} - h_{g1})$$

$$= \frac{1}{1.00773} \times 1.004(25 - 10) + \frac{1 \times 0.00773}{1.00773} (2547.17 - 2519.74)$$

$$= 14.9445 + 0.210407 = \textbf{15.15 kW}$$

11.69

If I have air at 100 kPa and a) –10°C b) 45°C and c) 110°C what is the maximum absolute humidity I can have?

Humidity is related to relative humidity (max 100%) and the pressures as in Eq.11.28 where from Eq.11.25 $P_v = \Phi\, P_g$ and $P_a = P_{tot} - P_v$.

$$\omega = 0.622 \frac{P_v}{P_a} = 0.622 \frac{\Phi\, P_g}{P_{tot} - \Phi P_g}$$

a) $P_g = 0.2601$ kPa, $\omega = 0.622 \times \dfrac{0.2601}{100 - 0.26} =$ **0.001 62**

b) $P_g = 9.593$ kPa, $\omega = 0.622 \times \dfrac{9.593}{100 - 9.593} =$ **0.0660**

c) $P_g = 143.3$ kPa, **no limit** on ω for $P_{tot} = 100$ kPa

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.70

A new high-efficiency home heating system includes an air-to-air heat exchanger which uses energy from outgoing stale air to heat the fresh incoming air. If the outside ambient temperature is –10°C and the relative humidity is 50%, how much water will have to be added to the incoming air, if it flows in at the rate of 1 m^3/s and must eventually be conditioned to 20°C and 45% relative humidity?

Solution:

Outside ambient air: $P_{v1} = \phi_1 P_{g1} = 0.50 \times 0.2602 = 0.1301$ kPa

Assuming $P_1 = P_2 = 100$ kPa, => $P_{A1} = 100 - 0.1301 = 99.87$ kPa

$$\dot{m}_A = \frac{P_{A1}\dot{V}_1}{R_A T_1} = \frac{99.87 \times 1}{0.287 \times 263.2} = 1.3224 \text{ kg/s}$$

From Eq.11.28: $w_1 = 0.622 \times \frac{0.1301}{99.87} = 0.00081$

Conditioned to : $T_2 = 20\ ^oC$, $\phi_2 = 0.45$

Eq.11.25: $P_{v2} = \phi_2 P_{g2} = 0.45 \times 2.339$ kPa $= 1.0526$ kPa =>

Eq.11.28: $w_2 = 0.622 \times \frac{1.0526}{100 - 1.0526} = 0.00662$

Continuity equation for water,

$$\dot{m}_{liq\ in} = \dot{m}_A(w_2 - w_1) = 1.3224\ (0.00662 - 0.00081)$$
$$= 0.007683 \text{ kg/s} = \mathbf{27.66\ kg/h}$$

11.71

Consider 100 m^3 of atmospheric air which is an air–water vapor mixture at 100 kPa, 15°C, and 40% relative humidity. Find the mass of water and the humidity ratio. What is the dew point of the mixture?

Solution:

Air-vapor P = 100 kPa, T = 15 ^oC, ϕ = 40%

Use Table B.1.1 and then Eq.11.25

$P_g = P_{sat15} = 1.705$ kPa => $P_v = \phi P_g = 0.4 \times 1.705 = 0.682$ kPa

$$m_v = \frac{P_v V}{R_v T} = \frac{0.682 \times 100}{0.461 \times 288.15} = \mathbf{0.513\ kg}$$

$P_a = P_{tot} - P_{v1} = 100 - 0.682 = 99.32$ kPa

$$m_a = \frac{P_a V}{R_a T} = \frac{99.32 \times 100}{0.287 \times 288.15} = 120.1 \text{ kg}$$

$$w_1 = \frac{m_v}{m_a} = \frac{0.513}{120.1} = \mathbf{0.0043}$$

T_{dew} is T when $P_v = P_g = 0.682$ kPa;

Table B.1.2 gives T = **1.4 ^oC**

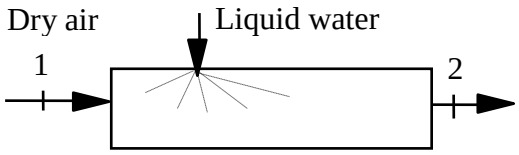
11.72

A flow of 2 kg/s completely dry air at T_1, 100 kPa is cooled down to 10°C by spraying liquid water at 10°C, 100 kPa into it so it becomes saturated moist air at 10°C. The process is steady state with no external heat transfer or work. Find the exit moist air humidity ratio and the flow rate of liquid water. Find also the dry air inlet temperature T_1.

Solution:

2: saturated $P_v = P_g = 1.2276$ kPa and h_{fg} (10°C)= 2477.7 kJ/kg

Eq.11.25: $w_2 = 0.622 \times 1.2276/ (100 - 1.2276) =$ **0.00773**



C.V. Box

Continuity Eq.: $\dot{m}_a + \dot{m}_{liq} = \dot{m}_a(1 + w_2)$ =>

$\dot{m}_{liq} = w_2 \dot{m}_a =$ **0.0155 kg/s**

Energy Eq.: $\dot{m}_a h_{a1} + \dot{m}_{liq} h_f = \dot{m}_a (h_{a2} + w_2 h_{g2})$

$h_{a1} - h_{a2} = C_{pa} (T_1 - T_2) = w_2 h_{g2} - w_2 h_f = w_2 h_{fg}$

$= 0.0073$ kg/kg dry air $\times$ 2477.75 kJ/kg = 9.15 kJ/kg dry air

$T_1 = T_2 + (h_{a1} - h_{a2})/C_{pa} = 10 + 9.15/1.004 =$ **29.1°C**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.73

The products of combustion are flowing through a heat exchanger with 12% CO_2, 13% H_2O and 75% N_2 on a volume basis at the rate 0.1 kg/s and 100 kPa. What is the dew-point temperature? If the mixture is cooled 10°C below the dew-point temperature, how long will it take to collect 10 kg of liquid water?

Solution:

Volume basis is the same as mole fraction

$$y_{H_2O} = 0.13; \quad P_{H_2O} = y_{H_2O}\, P = 0.13 \times 100 \text{ kPa} = 13 \text{ kPa},$$

Table B.1.2 $T_{DEW} = \mathbf{50.95\ ^oC}$

Cool to 40.95 ^oC < T_{DEW} so saturated $\rightarrow P_G = 7.805$ kPa

$$y_{H_2O} = P_G/P = 7.805/100 = n_{H_2O(v)}/(n_{H_2O(v)} + 0.87)$$

$$n_{H_2O(v)} = 0.07365 \text{ per kmol mix in}$$

$$\rightarrow n_{LIQ} = 0.13 - 0.07365 = 0.05635$$

Eq.11.5: $M_{MIX\ IN} = 0.12 \times 44.01 + 0.13 \times 18.015 + 0.75 \times 28.013 = 28.63$ kg/kmol

$$\dot{n}_{MIX\ IN} = \dot{m}_{TOTAL}/M_{MIX\ IN} = \frac{0.1 \text{ kg/s}}{28.63 \text{ kg/kmol}} = 0.003493 \text{ kmol/s}$$

$$\dot{n}_{LIQ\ COND} = 0.003\,493 \times 0.05635 = 0.000\,197 \text{ kmol/s}$$

$$\text{or } \dot{m}_{LIQ\ COND} = 0.000\,197 \text{ kmol/s} \times 18.015 \text{ kg/kmol} = 0.003\,55 \text{ kg/s}$$

For 10 kg, it takes: $\Delta t = m/\dot{m} = \frac{10 \text{ kg}}{0.00355 \text{ kg/s}} \sim$ **47 minutes**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.74

Consider a 1 m^3/s flow of atmospheric air at 100 kPa, 25°C, and 80% relative humidity. Assume this flows into a basement room where it cools to 15°C, 100 kPa. Find the rate of water condensing out and the exit mixture volume flow rate.

Solution:

State 1: $P_g = P_{sat25} = 3.169$ kPa => $P_v = \phi P_g = 0.8 \times 3.169 = 2.535$ kPa

$$\dot{m}_{v1} = \frac{P_v \dot{V}}{R_v T} = \frac{2.535 \times 1}{0.461 \times 298.15} = 0.0184 \text{ kg/s}$$

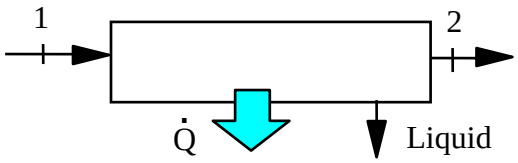
$$w_1 = \frac{\dot{m}_{v1}}{\dot{m}_{A1}} = 0.622 \frac{P_{v1}}{P_{A1}} = 0.622 \frac{2.535}{100 - 2.535} = 0.0162$$

$$\dot{m}_{A1} = \frac{\dot{m}_{v1}}{w_1} = \frac{0.0184}{0.0162} = 1.136 \text{ kg/s} = \dot{m}_{A2} \qquad \text{(continuity for air)}$$

Check for state 2:

$P_{g15°C} = 1.705$ kPa $<$ P_{v1}

so liquid water out.



State 2 is saturated $\phi_2 = 100\%$, $P_{v2} = P_{g2} = 1.705$ kPa

$$w_2 = 0.622 \frac{P_{v2}}{P_{A2}} = 0.622 \frac{1.705}{100 - 1.705} = 0.0108$$

$$\dot{m}_{v2} = w_2 \dot{m}_{A2} = 0.0108 \times 1.136 = 0.0123 \text{ kg/s}$$

$$\dot{m}_{liq} = \dot{m}_{v1} - \dot{m}_{v2} = 0.0184 - 0.0123 = \mathbf{0.0061 \text{ kg/s}}$$

$$\dot{V} = \frac{\dot{m}_{A2} R_a T_2}{P_{a2}} = \frac{\dot{m}_{A2} R_a T_2}{P - P_{v2}} = \frac{1.136 \times 0.287 \times 288.15}{100 - 1.705} = \mathbf{0.956 \text{ m}^3/\text{s}}$$

Note that the given volume flow rate at the inlet is not that at the exit. The mass flow rate of dry air is the quantity that is the same at the inlet and exit.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.75

Ambient moist air enters a steady-flow air-conditioning unit at 102 kPa, 30°C, with a 60% relative humidity. The volume flow rate entering the unit is 100 L/s. The moist air leaves the unit at 95 kPa, 15°C, with a relative humidity of 100%. Liquid also leaves the unit at 15°C. Determine the rate of heat transfer for this process.

Solution:

State 1: $P_{V1} = \phi_1 P_{G1} = 0.60 \times 4.246 = 2.5476$

$w_1 = 0.622 \times 2.5476/(102 - 2.5476) = 0.01593$

$$\dot{m}_A = \frac{P_{A1}\dot{V}_1}{R_A T_1} = \frac{99.45 \times 0.1}{0.287 \times 303.2} = 0.1143 \text{ kg/s}$$

$P_{v2} = P_{g2} = 1.705$ kPa, $w_2 = 0.622 \times 1.705/(95 - 1.705) = 0.01137$

Energy Eq.4.10: $\dot{Q}_{CV} + \dot{m}_A h_{A1} + \dot{m}_{V1} h_{V1} = \dot{m}_A h_{A2} + \dot{m}_{V2} h_{A2} + \dot{m}_3 h_{L3}$

$$\dot{Q}_{CV}/\dot{m}_A = C_{P0A}(T_2 - T_1) + w_2 h_{V2} - w_1 h_{V1} + (w_1 - w_2) h_{L3}$$

$$= 1.004(15-30) + 0.01137 \times 2528.9 - 0.01593 \times 2556.2$$

$$+ 0.00456 \times 63.0 = -26.732 \text{ kJ/kg air}$$

$\dot{Q}_{CV} = 0.1143(-26.73) =$ **-3.055 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.76

A room with air at 40% relative humidity, 20°C having 50 kg of dry air is made moist by boiling water to a final state of 20°C and 80% humidity. How much water was added to the air?

The water content is expressed by the absolute humidity (humidity ratio) from Eq.11.28 and 11.25

$$w_1 = 0.622 \times \frac{0.4 \times 2.339}{101.325 - 0.4 \times 2.339} = 0.005797$$

$$w_2 = 0.622 \times \frac{0.8 \times 2.339}{101.325 - 0.8 \times 2.339} = 0.011703$$

$$m_{water} = m_a (w_2 - w_1) = 50 \text{ kg } (0.011703 - 0.005797) = \mathbf{0.295 \text{ kg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.77

Consider a 500-L rigid tank containing an air–water vapor mixture at 100 kPa, 35°C, with a 70% relative humidity. The system is cooled until the water just begins to condense. Determine the final temperature in the tank and the heat transfer for the process.

Solution:

$P_{v1} = \phi P_{G1} = 0.7 \times 5.628 = 3.9396$ kPa

Since m_v = const & V = const & also $P_v = P_{G2}$:

$P_{G2} = P_{v1} \times T_2/T_1 = 3.9396 \times T_2/308.2 = 0.01278\ T_2$

Assume $T_2 = 30^oC$: $\quad 0.01278 \times 303.2 = 3.875 \neq 4.246 = P_{G\ 30C}$

Assume $T_2 = 25^oC$: $\quad 0.01278 \times 298.2 = 3.811 \neq 3.169 = P_{G\ 25C}$

interpolating $\rightarrow T_2 =$ **28.2 °C**

$$w_2 = w_1 = 0.622 \frac{3.9396}{(100\text{-}3.9369)} = 0.025\ 51$$

$m_a = P_{a1}V/R_aT_1 = (100\text{-}3.94) \times 0.5/(0.287 \times 308.2) = 0.543$ kg

Energy Eq.:

$$_1Q_2 = U_2\text{-}U_1 = m_a(u_{a2}\text{-}u_{a1}) + m_v(u_{v2}\text{-}u_{v1})$$

$$= m_a[\ C_v\ (T_{a2}\text{-}T_{a1}) + w_1\ (u_{v2}\text{-}u_{v1})\ ]$$

$$= 0.543\ [0.717(28.2 - 35) + 0.02551\ (2414.2 - 2423.4)\ ]$$

$$= 0.543 \text{ kg } (-5.11 \text{ kJ/kg}) = \textbf{-2.77 kJ}$$

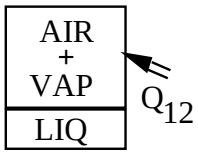
11.78

A saturated air-water vapor mixture at 20 °C, 100 kPa, is contained in a 5-m^3 closed tank in equilibrium with 1 kg of liquid water. The tank is heated to 80°C. Is there any liquid water in the final state? Find the heat transfer for the process.



a) Since $V_{liq} = m_{liq} v_F \approx 0.001$ m^3, $V_{GAS} \approx V$

$\phi_1 = 1.00 \rightarrow P_{v1} = P_{G1} = 2.339$ kPa

$w_1 = 0.622 \times 2.339 / (100 - 2.339) = 0.0149$

$$m_a = \frac{P_{a1} V}{R_a T_1} = \frac{97.661 \times 4.999}{0.287 \times 293.2} = 5.802 \text{ kg} \quad \Rightarrow \quad m_{v1} = w_1 m_a = 0.086 \text{ kg}$$

At state 2: $$P_{a2} = 97.661 \text{ kPa} \times \frac{353.2}{293.2} \times \frac{4.999}{5} = 117.623 \text{ kPa}$$

$$w_{MAX\ 2} = 0.622 \times 47.39 / 117.623 = 0.2506$$

But $$w_{2\ ACTUAL} = \frac{0.086 + 1.0}{5.802} = 0.1872 < w_{MAX\ 2} \quad \rightarrow \textbf{No liquid at 2}$$

$$m_{v2} = m_{v1} + m_{liq} = 0.086 \text{ kg} + 1 \text{ kg} = 1.086 \text{ kg}$$

$$Q_{12} = m_a (u_{a2} - u_{a1}) + m_{v2} u_{v2} - m_{v1} u_{v1} - m_{liq\ 1} u_{liq\ 1}$$

$$= m_a C_v (T_{a2} - T_{a1}) + m_{v2} u_{v2} - m_{v1} u_{v1} - m_{liq\ 1} u_{liq\ 1}$$

$$= 5.802 \times 0.717(80 - 20) + 1.086 \times 2482.2 - 0.086 \times 2402.9 - 1 \times 84.0$$

$$= 249.6 + 2695.7 - 206.65 - 84 = \textbf{2655 kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.79

A flow of 0.2 kg/s liquid water at 80°C is sprayed into a chamber together with 16 kg/s dry air at 60°C. All the water evaporates and the air leaves at 40°C. What is the exit relative humidity and the heat transfer.

CV. Chamber.

Continuity Eq. water: $\dot{m}_{liq} = w_{ex}\, \dot{m}_a$

Energy Eq.: $\dot{m}_{liq}\, h_{liq} + \dot{m}_a\, h_{a\,i} + \dot{Q} = \dot{m}_a\, (wh_v + h_a)_{ex}$

$w_{ex} = \dot{m}_{liq} / \dot{m}_a = 0.2 / 16 = 0.0125$

From Eq.11.25 and 11.28 you can get

$$\phi_{ex} = P_v / P_g = \frac{w}{0.622 + w}\frac{P}{P_g} = \frac{0.0125}{0.622 + 0.0125} \times \frac{100}{7.384} = \mathbf{0.267 = 27\%}$$

$$\dot{Q} = \dot{m}_a\, (wh_v + h_a)_{ex} - \dot{m}_{liq}\, h_{liq} + \dot{m}_a\, h_{a\,i} = \dot{m}_a (\, h_{a\,ex} - h_{a\,i}) + \dot{m}_{liq}(h_v - h_{liq})$$

$$= \dot{m}_a\, C_{p\,a}\, (T_{ex} - T_{in}) + \dot{m}_{liq}\, (h_{v\,40} - h_{f\,80})$$

$$= 16 \times 1.004\, (40 - 60) + 0.2\, (2574.26 - 334.88)$$

$$= -321.28 + 447.88 = \mathbf{126.6\ kW}$$

11.80

A rigid container, 10 m^3 in volume, contains moist air at 45°C, 100 kPa, ϕ = 40%. The container is now cooled to 5°C. Neglect the volume of any liquid that might be present and find the final mass of water vapor, final total pressure and the heat transfer.

Solution:

CV container. $m_2 = m_1$; $m_2u_2 - m_1u_1 = {}_1Q_2$

State 1: 45°C, ϕ = 40% => $w_1 = 0.0236$, $T_{dew} = 27.7°C$

Final state $T_2 < T_{dew}$ so condensation, $\phi_2 = 100\%$

$P_{v1} = 0.4\ P_g = 0.4 \times 9.593 = 3.837$ kPa, $P_{a1} = P_{tot} - P_{v1} = 96.163$ kPa

$m_a = P_{a1}V/RT_1 = 10.532$ kg, $m_{v1} = w_1\ m_a = 0.248$ kg

$P_{v2} = P_{g2} = 0.8721$ kPa, $P_{a2} = P_{a1}T_2/T_1 = 84.073$ kPa

$P_2 = P_{a2} + P_{v2} =$ **84.95 kPa**

$m_{v2} = P_{v2}V/R_vT_2 =$ **0.06794 kg** (= $V/v_g = 0.06797$ steam table)

$m_{f2} = m_{v1} - m_{v2} = 0.180$ kg

The heat transfer from the energy equation becomes

$${}_1Q_2 = m_a(u_2-u_1)_a + m_{v2}u_{g2} + m_{f2}u_{f2} - m_{v1}u_{g1}$$

$$= m_a\ C_v(T_2 - T_1) + m_{v2}\ 2382.3 + m_{f2}\ 20.97 - m_{v1}\ 2436.8$$

$$= -302.06 + 161.853 + 3.775 - 604.33 = -$$ **740.8 kJ**

11.81

A water-filled reactor of 1 m^3 is at 20 MPa, 360°C and located inside an insulated containment room of 100 m^3 that contains air at 100 kPa and 25°C. Due to a failure the reactor ruptures and the water fills the containment room. Find the final pressure.

CV Total container.

$$m_v\,(u_2 - u_1) + m_a\,(u_2 - u_1) = {}_1Q_2 - {}_1W_2 = 0$$

Initial water: $v_1 = 0.0018226$, $u_1 = 1702.8$ kJ/kg, $m_v = V/v = 548.67$ kg

Initial air: $$m_a = \frac{PV}{RT} = \frac{100 \times 99}{0.287 \times 298.2} = 115.7 \text{ kg}$$

Substitute into energy equation

$$548.67\,(u_2 - 1702.8) + 115.7 \times 0.717\,(T_2 - 25) = 0$$

$$u_2 + 0.1511\,T_2 = 1706.6 \text{ kJ/kg} \quad \& \quad v_2 = V_2/m_v = 0.18226 \text{ m}^3/\text{kg}$$

Trial and error 2-phase (T_{guess}, v_2 => x_2 => u_2 => LHS)

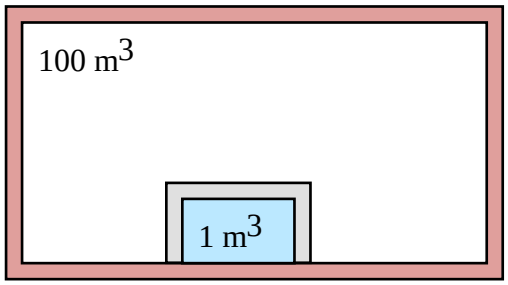
T = 150°C LHS = 1546 T = 160°C LHS = 1820.2

T = 155°C LHS = 1678.1 => T = 156°C LHS = 1705.7 OK

$x_2 = 0.5372$, $P_{sat} = 557.5$ kPa

$$P_{a2} = P_{a1}V_1T_2/V_2T_1 = 100 \times 99 \times 429.15 / (100 \times 298.15) = 142.5 \text{ kPa}$$

$$\Rightarrow \quad P_2 = P_{a2} + P_{sat} = \mathbf{700\ kPa.}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.82

In the production of ethanol from corn the solids left after fermentation are dried in a continuous flow oven. This process generates a flow of 15 kg/s moist air, 90°C with 70% relative humidity, which contains some volatile organic compounds and some particles. To remove the organic gasses and the particles, the flow is send to a **thermal oxidicer** where natural gas flames brings the mixture to 800°C. Find the rate of heating by the natural gas burners.

For this problem we will just consider the heating of the gas mixture and due to the exit temperature we will use the ideal gas tables A7 and A8.

Eq.11.25: $P_v = \phi P_g = 0.70 \times 70.14 = 49.098$ kPa

Eq.11.28: $\omega = 0.622 \dfrac{P_v}{P_{tot} - P_v} = 0.622 \times \dfrac{49.098}{100 - 49.098} = 0.60$

Flow: $\dot{m}_{tot} = \dot{m}_a + \dot{m}_v = \dot{m}_a(1 + \omega)$ so

$$\dot{m}_a = \frac{\dot{m}_{tot}}{1 + \omega} = 9.375 \text{ kg/s}; \quad \dot{m}_v = \dot{m}_{tot} \frac{\omega}{1 + \omega} = 5.625 \text{ kg/s}$$

Process: Heating => ω is constant => P_v is constant

For ideal gas the enthalpy does not depend on pressure so the energy equation gives the heat transfer as

$$\dot{Q} = \dot{m}_a (h_2 - h_1)_a + \dot{m}_v (h_2 - h_1)_v$$
$$= 9.375 (1130.2 - 364.0) + 5.625 (2164.3 - 672.75)$$
$$= \mathbf{15\ 573\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.83

To save on natural gas use in the previous problem it is suggested to take and cool the mixture and condense out some water before heating it back up. So the flow is cooled from 90°C to 50°C and the now dryer mixture is heated to 800°C. Find the amount of water condensed out and the rate of heating by the natural gas burners for this case.

Eq.11.25: $P_{v1} = \phi_1 P_g = 0.70 \times 70.14 = 49.098$ kPa

Eq.11.28: $\omega_1 = 0.622 \dfrac{P_v}{P_{tot} - P_v} = 0.622 \times \dfrac{49.098}{100 - 49.098} = 0.60$

Flow: $\dot{m}_{tot} = \dot{m}_a + \dot{m}_v = \dot{m}_a(1 + \omega)$ so

$$\dot{m}_a = \frac{\dot{m}_{tot}}{1 + \omega} = 9.375 \text{ kg/s}; \quad \dot{m}_{v1} = \dot{m}_{tot} \frac{\omega}{1 + \omega} = 5.625 \text{ kg/s}$$

Now cool to 50°C: $P_g = 12.35$ kPa $< P_{v1}$ so $\phi_2 = 100\%$, $P_{v2} = 12.35$ kPa

$$\omega_2 = 0.622 \frac{P_v}{P_{tot} - P_v} = 0.622 \times \frac{12.35}{100 - 12.35} = 0.0876$$

$$\dot{m}_{liq} = \dot{m}_a (\omega_1 - \omega_2) = 9.375 (0.6 - 0.0876) = \mathbf{4.80375 \text{ kg/s}}$$

The air flow is not changed so the water vapor flow for heating is

$$\dot{m}_{v2} = \dot{m}_{v1} - \dot{m}_{liq} = 5.625 - 4.80375 = 0.82125 \text{ kg/s}$$

Now the energy equation becomes

$$\dot{Q} = \dot{m}_a (h_3 - h_2)_a + \dot{m}_{v2} (h_3 - h_2)_v$$
$$= 9.375 (1130.2 - 323.75) + 0.82125 (2164.3 - 597.65)$$
$$= \mathbf{8847 \text{ kW}}$$

Comment: If you solve the previous problem you find this is only 57% of the heat for the case of no water removal.

11.84

I want to bring air at 35^{o}C, Φ = 40% to a state of 25^{o}C, ω = 0.015 do I need to add or subtract water?

The humidity ratio (absolute humidity) expresses how much water vapor is present in the mixture

$$\omega = m_v / m_a$$

Assuming P = 100 kPa,

$$\omega = 0.622 \frac{P_v}{P_a} = 0.622 \frac{P_v}{P - P_v} \quad \text{and} \quad P_v = \Phi P_g$$

At 35°C, 40 % :

$$\omega = 0.622 \times \frac{0.40 \times 5.628}{100 - 0.40 \times 5.628} = 0.014\ 32$$

To get to ω = 0.015 , it is necessary to **add water**.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.85

A flow moist air at 100 kPa, 40°C, 40% relative humidity is cooled to 15°C in a constant pressure device. Find the humidity ratio of the inlet and the exit flow, and the heat transfer in the device per kg dry air.

Solution:

C.V. Cooler. $\dot{m}_{v1} = \dot{m}_{liq} + \dot{m}_{v2}$

Tables: $P_{g1} = 7.384$ kPa, $P_{v1} = \phi P_g = 0.4 \times 7.384 = 2.954$ kPa,

$\omega_1 = 0.622 \times 2.954 /(100 - 2.954) = 0.0189$

$T_2 < T_{dew}$ [from $P_g(T_{dew}) = 2.954$] => $P_{v2} = 1.705$ kPa $= P_{g2}$ =>

$\omega_2 = 0.622 \times 1.705 /(100 - 1.705) = 0.0108$

$h_{v1} = 2574.3$ kJ/kg, $h_{v2} = 2528.9$ kJ/kg, $h_f = 62.98$ kJ/kg

$\tilde{q}_{out} = C_P(T_1 - T_2) + \omega_1 h_{v1} - \omega_2 h_{v2} - (\omega_1 - \omega_2) h_f$

$= 1.004(40 - 15) + 0.0189 \times 2574.3 - 0.0108 \times 2528.9 - 0.0073 \times 62.98$

= **45.98 kJ/kg dry air**

Psychrometric chart: State 2: $T < T_{dew} = 23$°C => $\phi_2 = 100\%$

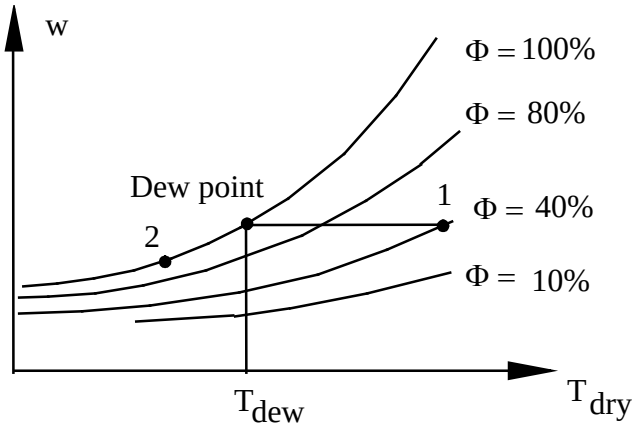
$\dot{m}_{v1}/\dot{m}_a = \omega_1 = 0.018$, $\tilde{h}_1 = 106$; $\dot{m}_{v2}/\dot{m}_a = \omega_2 = 0.0107$, $\tilde{h}_2 = 62$

$\dot{m}_{liq}/\dot{m}_a = \omega_1 - \omega_2 = 0.0073$, $h_f = 62.98$ kJ/kg

$\dot{m}_a \tilde{q}_{out} = \dot{m}_a \tilde{h}_1 - \dot{m}_{liq} h_f - \dot{m}_a \tilde{h}_2$ =>

$\tilde{q}_{out} = \tilde{h}_1 - (\omega_1 - \omega_2) h_f - \tilde{h}_2 = 106 - 0.0073 \times 62.98 - 62$

= **43.54 kJ/kg-dry air**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.86

Use the formulas and the steam tables to find the missing property of: ϕ, ω, and T_{dry}, total pressure is 100 kPa; repeat the answers using the psychrometric chart

a. $\phi = 50\%$, $\omega = 0.010$ b. $T_{dry} = 25°C$, $T_{wet} = 21°C$

Solution:

a. From Eq.11.28 with $P_a = P - P_v$ solve for P_v:

$$P_v = P\,\omega/(0.622 + \omega) = 100 \times 0.01/0.632 = 1.582 \text{ kPa}$$

From Eq.11.25 $P_g = P_v/\phi = 1.582/0.5 = 3.165$ kPa => **T = 25°C**

b. At 21°C:: $P_g = 2.505$ => $\omega_2 = 0.622 \times 2.505/(100 - 2.505) = 0.016$

From the steam tables B.1.1

$h_{f2} = 88.126$ and $h_{fg2} = 2451.76$ kJ/kg, $h_{v1} = 2547.17$

From Eq.11.30:

$$\omega_1 = [C_p(T_2 - T_1) + \omega_2 h_{fg2}]/(h_{v1} - h_{f2}) = \mathbf{0.0143}$$

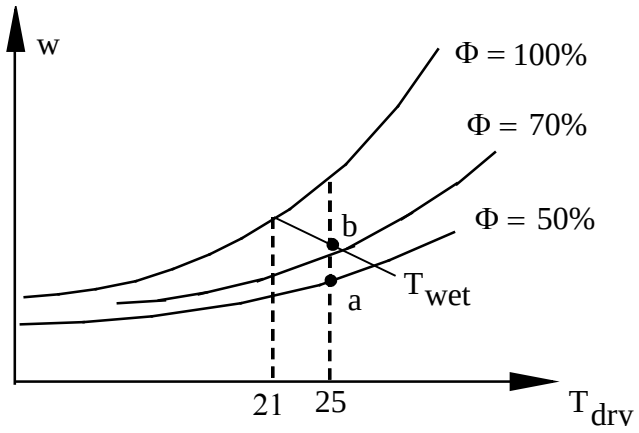
From Eq.11.28 with $P_a = P - P_v$ solve for P_v:

$$P_v = P\,\omega/(0.622 + \omega) = 2.247 \text{ kPa},$$

From Eq.11.25: $\phi = 2.247/3.169 = \mathbf{0.71}$

Using the psychrometric chart E.4:

a: $\boldsymbol{T_{dry} = 25.3\ °C}$ b: $\boldsymbol{\omega = 0.0141}$, $\boldsymbol{\phi = 71\text{-}72\%}$

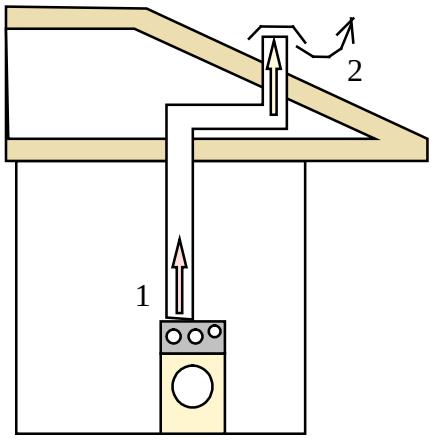


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.87

The discharge moist air from a clothes dryer is at 40°C, 80% relative humidity. The flow is guided through a pipe up through the roof and a vent to the atmosphere. Due to heat transfer in the pipe the flow is cooled to 24°C by the time it reaches the vent. Find the humidity ratio in the flow out of the clothes dryer and at the vent. Find the heat transfer and any amount of liquid that may be forming per kg dry air for the flow.

Solution:



State 1: Just outside chart

$P_a = 0.8 \times 7.384 = 5.907$ kPa

$\omega_1 = 0.622 \times 5.907 / (100 - 5.907)$

$= \mathbf{0.0390}$,

$T_{dew} = 35.8^{o}C$

State 2: $24^{o}C < T_{dew}$ so it is saturated.

$\omega_2 = \mathbf{0.019}$,

$\dot{m}_{liq}/\dot{m}_a = \omega_1 - \omega_2 = \mathbf{0.0099\ kg/kg\ dry\ air}$

Energy Eq.:

$$\dot{Q}/\dot{m}_a = (h_{a2} + \omega_2 h_{v2}) - (h_{a1} + \omega_1 h_{v1}) + (\omega_1 - \omega_2) h_f$$

$$= C_{pa} (T_2 - T_1) + \omega_2 h_{v2} - \omega_1 h_{v1} + (\omega_1 - \omega_2) h_f$$

$$= 1.004(24 - 40) + 0.019 \times 2545.1 - 0.039 \times 2574.3 + 0.0099 \times 100.7$$

$$= \mathbf{-67\ kJ/kg\ dry\ air}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.88

A flow, 0.2 kg/s dry air, of moist air at 40°C, 50% relative humidity flows from the outside state 1 down into a basement where it cools to 16°C, state 2. Then it flows up to the living room where it is heated to 25°C, state 3. Find the dew point for state 1, any amount of liquid that may appear, the heat transfer that takes place in the basement and the relative humidity in the living room at state 3.

Solve using psychrometric chart:

a) $T_{dew} = 27.2$ ($w = w_1$, $\phi = 100\%$) $\quad w_1 = 0.0232$, $\quad \tilde{h}_1 = 118.2$ kJ/kg air

b) $T_2 < T_{dew}$ so we have $\phi_2 = 100\%$ liquid water appear in the basement.

$\Rightarrow w_2 = 0.0114 \quad \tilde{h}_2 = 64.4$ and from steam tbl. $h_f = 67.17$

$\dot{m}_{liq} = \dot{m}_{air}(w_1 - w_2) = 0.2(0.0232 - 0.0114) = 0.00236$ kg/s

c) Energy equation: $\dot{m}_{air}\,\tilde{h}_1 = \dot{m}_{liq}\,h_f + \dot{m}_{air}\,\tilde{h}_2 + \dot{Q}_{out}$

$$\dot{Q}_{out} = 0.2[118.2 - 64.4 - 0.0118 \times 67.17] = 10.6 \text{ kW}$$

d) $w_3 = w_2 = 0.0114$ & $25°C \Rightarrow \phi_3 = 58\%$.

If you solve by the formulas and the tables the numbers are:

$P_{g40} = 7.384$ kPa; $P_{v1} = \phi\, P_{g40} = 0.5 \times 7.384 = 3.692$ kPa

$w_1 = 0.622 \times 3.692 / (100 - 3.692) = 0.02384$

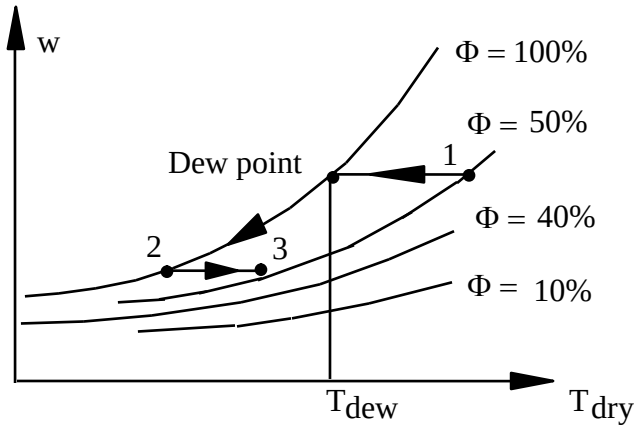
$P_{v1} = P_g(T_{dew}) \Rightarrow T_{dew\,1} = 27.5$ °C

2: $\phi = 100\%$, $P_{v2} = P_{g2} = 1.832$ kPa, $w_2 = 0.622 \times 1.832/98.168 = 0.0116$

$\dot{m}_{liq} = \dot{m}_{air}(w_1 - w_2) = 0.2 \times 0.01223 = 0.00245$ kg/s

3: $w_3 = w_2 \Rightarrow P_{v3} = P_{v2} = 1.832$ kPa & $P_{g3} = 3.169$ kPa

$\phi_3 = P_v/P_g = 1.832/3.169 = 57.8\%$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.89

A steady supply of 1.0 m^3/s air at 25°C, 100 kPa, 50% relative humidity is needed to heat a building in the winter. The outdoor ambient is at 10°C, 100 kPa, 50% relative humidity. What are the required liquid water input and heat transfer rates for this purpose?

Solution:

Air: $R_a = 0.287$ kJ/kg K, $C_p = 1.004$ kJ/kg-K

State 1: $T_1 = 10°C$, $\phi_1 = 50\%$, $P_1 = 100$ kPa

$P_{g1} = 1.2276$ kPa, $P_{v1} = \phi_1 P_{g1} = 0.6138$ kPa,

$P_{a1} = P_1 - P_{v1} = 99.39$ kPa => $\omega_1 = 0.622\, P_{v1}/P_{a1} = 0.003841$

State 2: $T_2 = 25°C$, $P_2 = 100$ kPa, $\phi_2 = 50\%$, $\dot{V}_2 = 1$ m^3/s

$P_{g2} = 3.169$ kPa, $P_{v2} = \phi_2 P_{g2} = 1.5845$ kPa,

$P_{a2} = P_2 - P_{v2} = 98.415$ kPa, $\omega_2 = 0.622\, P_{v2}/P_{a2} = 0.010014$

$$\dot{m}_{a2} = P_{a2}\dot{V}_2/R_a T_2 = 98.415 \times 1/(0.287 \times 298.15) = 1.15 \text{ kg/s}$$

Steam tables B.1.1: $h_{v1} = 2519.7$ kJ/kg, $h_{v2} = 2547.2$ kJ/kg

State 3: Assume liq. water at $T_3 = 25°C$, $h_{f3} = 104.9$ kJ/kg

Conservation of Mass: $\dot{m}_{a1} = \dot{m}_{a2}$, $\dot{m}_{f3} = \dot{m}_{v2} - \dot{m}_{v1}$

$$\dot{m}_{f3} = \dot{m}_{a2}(\omega_2 - \omega_1) = 1.15 \times 0.006173 = \mathbf{0.0071\ kg/s}$$

Energy Eq.: $\dot{Q} + \dot{m}_{a1}h_{a1} + \dot{m}_{v1}h_{v1} + \dot{m}_{f3}h_{f3} = \dot{m}_{a2}h_{a2} + \dot{m}_{v2}h_{v2}$

$$\tilde{q} = \frac{\dot{Q}}{\dot{m}_a} = C_p(T_2 - T_1) + \omega_2 h_{v2} - \omega_1 h_{v1} - \frac{\dot{m}_{f3}}{\dot{m}_a} h_{f3}$$

$$= 1.004(25 - 10) + 0.010014 \times 2547.2 - 0.003841 \times 2519.7 - 0.006173 \times 104.9$$

$$= 30.24 \text{ kJ/kg dry air}$$

$$\Rightarrow \quad \dot{Q} = \dot{m}_{a1}\,\tilde{q} = 1.15 \text{ kg/s} \times 30.24 \text{ kJ/kg} = \mathbf{34.78\ kW}$$

11.90

In a ventilation system inside air at 34°C and 70% relative humidity is blown through a channel where it cools to 25°C with a flow rate of 0.75 kg/s dry air. Find the dew point of the inside air, the relative humidity at the end of the channel, and the heat transfer in the channel.

C.V. Cooler. $\dot{m}_{v1} = \dot{m}_{liq} + \dot{m}_{v2}$

Tables: $P_{g1} = 5.352$ kPa, $P_{v1} = \phi P_g = 0.7 \times 5.352 = 3.75$ kPa,

$\omega_1 = 0.622 \times 3.75 / (101 - 3.75) = 0.024$

$T_2 < T_{dew} = 27$C [from $P_g(T_{dew}) = 3.75$] => $P_{v2} = 3.169$ kPa $= P_{g2}$

$\omega_2 = 0.622 \times 3.169 / (101 - 3.169) = 0.02015$

$h_{v1} = 2563.47$ kJ/kg, $h_{v2} = 2547.17$ kJ/kg, $h_f = 104.87$ kJ/kg

$\bar{q}_{out} = C_P(T_1 - T_2) + \omega_1 h_{v1} - \omega_2 h_{v2} - (\omega_1 - \omega_2) h_f$

$= 1.004(34 - 25) + 0.024 \times 2563.47 - 0.02015 \times 2547.17 - 0.00385 \times 104.87$

$= 18.83$ kJ/kg dry air

$\dot{Q} = \dot{m}_a \bar{q}_{out} = 0.75$ kg/s $\times$ 18.83 kJ/kg = **14.1 kW**

Psychrometric chart: State 2: $T < T_{dew} = 27.5$°C => $\phi_2 = 100\%$

$\dot{m}_{v1}/\dot{m}_a = \omega_1 = 0.0234$, $\tilde{h}_1 = 113.7$ kJ/kg air;

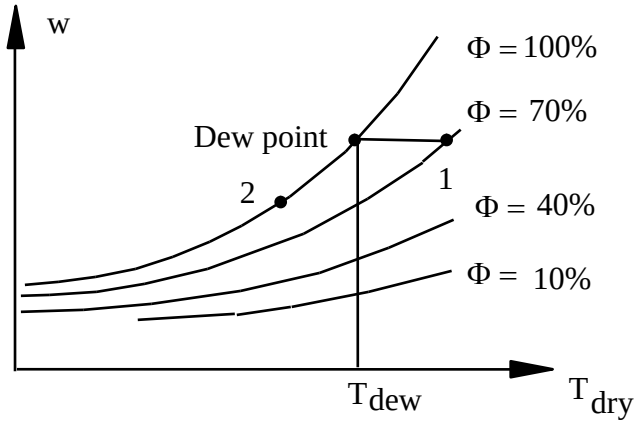
$\dot{m}_{v2}/\dot{m}_a = \omega_2 = 0.0202$, $\tilde{h}_2 = 96$ kJ/kg air

$\dot{m}_{liq}/\dot{m}_a = \omega_1 - \omega_2 = 0.0032$, $h_f = 104.87$ kJ/kg

$\dot{m}_a \tilde{q}_{out} = \dot{m}_a \tilde{h}_1 - \dot{m}_{liq} h_f - \dot{m}_a \tilde{h}_2$ =>

$\tilde{q}_{out} = \tilde{h}_1 - (\omega_1 - \omega_2) h_f - \tilde{h}_2 = 113.7 - 0.0032 \times 104.87 - 96 = 17.36$ kJ/kg-air

$\dot{Q} = \dot{m}_a \tilde{q}_{out} =$ **13.0 kW**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.91

Two moist air streams with 85% relative humidity, both flowing at a rate of 0.1 kg/s of dry air are mixed in a steady setup. One inlet flowstream is at 32.5°C and the other at 16°C. Find the exit relative humidity.

Solution:

CV mixing chamber.

Continuity Eq. water: $\dot{m}_{air}\, w_1 + \dot{m}_{air}\, w_2 = 2\dot{m}_{air}\, w_{ex}$;

Energy Eq.: $\dot{m}_{air}\, \tilde{h}_1 + \dot{m}_{air}\, \tilde{h}_2 = 2\dot{m}_{air}\, \tilde{h}_{ex}$

Properties from the tables and formulas

$P_{g32.5} = 4.937$ kPa; $P_{v1} = 0.85 \times 4.937$ kPa $= 4.196$ kPa

$w_1 = 0.622 \times 4.196 / (100 - 4.196) = 0.0272$

$P_{g16} = 1.831$ kPa; $P_{v2} = 0.85 \times 1.831$ kPa $= 1.556$ kPa

$w_2 = 0.622 \times 1.556 / (100 - 1.556) = 0.00983$

Continuity Eq. water: $w_{ex} = (w_1 + w_2)/2 = 0.0185$;

For the energy equation we have $\tilde{h} = h_a + w h_v$ so:

$2\tilde{h}_{ex} - \tilde{h}_1 - \tilde{h}_2 = 0 = 2h_{a\,ex} - h_{a\,1} - h_{a\,2} + 2w_{ex}h_{v\,ex} - w_1 h_{v\,1} - w h_{v\,2}$

we will use constant specific heat to avoid an iteration on T_{ex}.

$C_{p\,air}(2T_{ex} - T_1 - T_2) + C_{p\,H2O}(2w_{ex}T_{ex} - w_1T_1 - w_2T_2) = 0$

$T_{ex} = [\, C_{p\,air}(T_1 + T_2) + C_{p\,H2O}(w_1T_1 + w_2T_2)\,]/\,[2C_{p\,air} + 2w_{ex}C_{p\,H2O}]$

$= [\, 1.004\,(32.5 + 16) + 1.872(0.0272 \times 32.5 + 0.00983 \times 16]/2.0773$

$= 24.4$°C

$$P_{v\,ex} = \frac{w_{ex}}{0.622 + w_{ex}} P_{tot} = \frac{0.0185}{0.622 + 0.0185} 100 = 2.888 \text{ kPa},$$

$P_{g\,ex} = 3.069$ kPa => $\phi = 2.888 / 3.069 =$ **0.94 or 94%**

Properties taken from the psychrometric chart

State 1: $w_1 = 0.0266$, $\tilde{h}_1 = 120$ State 2: $w_2 = 0.0094$, $\tilde{h}_2 = 60$

Continuity Eq. water: $w_{ex} = (w_1 + w_2)/2 = 0.018$;

Energy Eq.: $\tilde{h}_{ex} = (\tilde{h}_1 + \tilde{h}_2)/2 = 90$ kJ/kg dry air

exit: w_{ex}, $\tilde{h}_{ex}$ => $T_{ex} =$ **24.5°C**, $\phi =$ **94%**

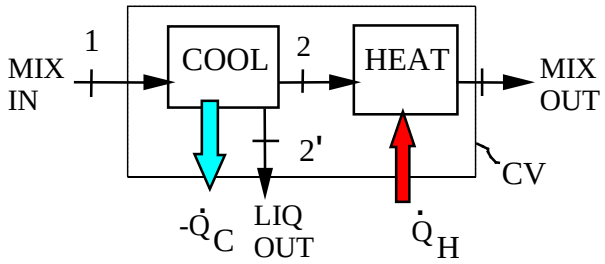
Notice how the energy in terms of temperature is close to the average of the two flows but the relative humidity is not.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.92

A combination air cooler and dehumidification unit receives outside ambient air at 35°C, 100 kPa, 90% relative humidity. The moist air is first cooled to a low temperature T_2 to condense the proper amount of water, assume all the liquid leaves at T_2. The moist air is then heated and leaves the unit at 20°C, 100 kPa, relative humidity 30% with volume flow rate of 0.01 m^3/s. Find the temperature T_2, the mass of liquid per kilogram of dry air and the overall heat transfer rate.

Solution:



$P_{v1} = \phi_1 P_{G1} = 0.9 \times 5.628 = 5.0652$ kPa

$$w_1 = 0.622 \times \frac{5.0652}{100\text{-}5.0652} = 0.033\ 19$$

$P_{v3} = \phi_3 P_{G3} = 0.3 \times 2.339 = 0.7017$ kPa

$$w_2 = w_3 = 0.622 \times \frac{0.7017}{100\text{-}0.7017} = 0.0044$$

$\dot{m}_{LIQ\ 2'}/\dot{m}_a = w_1 - w_2 = 0.033\ 19 - 0.0044 =$ **0.028 79 kg/kg air**

$P_{G2} = P_{v3} = 0.7017$ kPa $\rightarrow$ $T_2 =$ **1.7 °C**

For a C.V. around the entire unit

$$\dot{Q}_{CV} = \dot{Q}_H + \dot{Q}_C$$

Net heat transfer, Energy Eq.:

$$\dot{Q}_{CV}/\dot{m}_a = (h_{a3}\text{-}h_{a1}) + w_3 h_{v3} - w_1 h_{v1} + \dot{m}_{L2'} h_{L2'}/\dot{m}_a$$
$$= 1.004(20\text{-}35) + 0.0044 \times 2538.1 - 0.033\ 19 \times 2565.3 + 0.028\ 79 \times 7.28$$
$$= -88.82 \text{ kJ/kg air}$$

$$\dot{m}_a = \frac{P_{a3}\dot{V}_3}{R_a T_3} = \frac{(100\text{-}0.7017) \times 0.01}{0.287 \times 293.2} = 0.0118 \text{ kg/s}$$

$\dot{Q}_{CV} = 0.0118$ kg/s $\times$ (-88.82) kJ/kg air = **-1.05 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.93

To make dry coffee powder we spray 0.2 kg/s coffee (assume liquid water) at 80^{o} C into a chamber where we add 10 kg/s dry air at T. All the water should evaporate and the air should leave with a minimum 40^{o}C and we neglect the powder. How high should T in the inlet air flow be?

CV. Chamber. We assume it is adiabatic.

Continuity Eq. water alone: $\dot{m}_{liq} = w_{ex}\, \dot{m}_a$

Energy Eq.: $\dot{m}_{liq}\, h_{f\,80} + \dot{m}_a\, h_{a\,Ti} = \dot{m}_{liq}\, h_{v\,40} + \dot{m}_a\, h_{a\,40}$

$$w_{ex} = \dot{m}_{liq} / \dot{m}_a = 0.2 / 8 = 0.025$$

From the energy equation you get

$$h_{a\,Ti} - h_{a\,40} = C_{p\,a}\,(T_{in} - T_{ex}) = \dot{m}_{liq}\,(h_{v\,40} - h_{f\,80}) / \dot{m}_a$$

$$1.004\ \text{kJ/kg-K}\ \Delta T = 0.2\,(2574.26 - 334.88) / 10 = 44.788\ \text{kJ/kg}$$

$$\Delta T = 44.6^{o}\text{C} \quad \Rightarrow \quad T_{in} = 40 + 44.6 = \mathbf{84.6^{o}C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.94

An insulated tank has an air inlet, $\omega_1 = 0.0084$, and an outlet, $T_2 = 22°C$, $\phi_2 = 90\%$ both at 100 kPa. A third line sprays 0.25 kg/s of water at 80°C, 100 kPa. For steady operation find the outlet specific humidity, the mass flow rate of air needed and the required air inlet temperature, T_1.

Solution:

Take CV tank in steady state. Continuity and energy equations are:

Continuity Eq. water: $\dot{m}_3 + \dot{m}_a w_1 = \dot{m}_a w_2$

Energy Eq.: $\dot{m}_3 h_f + \dot{m}_a \tilde{h}_1 = \dot{m}_a \tilde{h}_2$

All state properties are known except T_1.

From the psychrometric chart we get

State 2: $w_2 =$ **0.015**, $\tilde{h}_2 = 79.5$ State 3: $h_f = 334.91$ (steam tbl)

$\dot{m}_a = \dot{m}_3/(w_2 - w_1) = 0.25/(0.015\text{-}0.0084) =$ **37.88 kg/s**

$\tilde{h}_1 = \tilde{h}_2 - (w_2 - w_1)h_f = 79.5 - 0.0066 \times 334.91 = 77.3$

Chart $(w_1, \tilde{h}_1)$ => $T_1 =$ **36.5°C**

Using the tables and formulas we get

State 2: $P_{g2} = 2.671$; $P_{v2} = 0.9 \times 2.671 = 2.4039$ kPa

$w_2 = 0.622 \times 2.4039 / (100 - 2.4039) =$ **0.0153**

$\dot{m}_a = \dot{m}_3/(w_2 - w_1) = 0.25/(0.0153 - 0.0084) =$ **36.23 kg/s**

To avoid iterations on T_1 we use specific heat values also for water vapor by writing $h_{v1} = h_{v2} + C_{p\,h2o}(T_1 - T_2)$ so the energy equation is

$$C_{p\,a} T_1 + w_1 C_{p\,h2o}(T_1 - T_2) + w_1 h_{v2} = C_{p\,a} T_2 + w_2 h_{v2} - (w_2 - w_1) h_f$$

The equation now becomes

$$(1.004 + 0.0084 \times 1.872)T_1 = (0.0084 \times 1.872 + 1.004)\, 22$$
$$+ (0.0153 - 0.0084)(2541.7 - 334.91) = 37.219$$
$$T_1 = \textbf{36.5°C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.95

An air flow 2 kg/s at 30°C, and relative humidity 80% is conditioned by taking half the flow, cooling it and mix it with the other half. Assume the outlet flow should have a water content that is 75% of the original flow. Find the temperature to cool to, the rate of cooling and the final exit flow temperature.

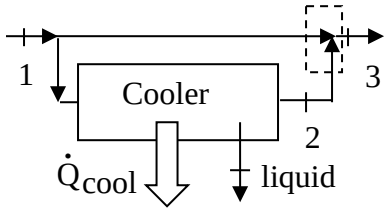


FIGURE P11.95

CV Total setup

Continuity water: $0 = \dot{m}_a\,\omega_1 - \dot{m}_{liq} - \dot{m}_a\,\omega_3$; $\dot{m}_{liq} = \dot{m}_a\,(\omega_1 - \omega_3)$

State 1: $P_{g1} = 4.246$; $P_{v1} = 0.8 \times 4.246 = 3.3968$ kPa

$\omega_1 = 0.622 \times 3.3968 / (100 - 3.3968) = 0.02187$

CV Junction

Continuity water: $0 = 0.5\,\dot{m}_a\,\omega_1 + 0.5\,\dot{m}_a\,\omega_2 - \dot{m}_a\,\omega_3$; $\omega_3 = 0.75\,\omega_1$

Energy Eq.: $0 = 0.5\,\dot{m}_a(h_{a1} + \omega_1 h_{v1}) + 0.5\,\dot{m}_a(h_{a2} + \omega_2 h_{v2}) - \dot{m}_a(h_{a3} + \omega_3\,h_{v3})$

Solve for ω_2: $\omega_2 = 2\,\omega_3 - \omega_1 = 1.5\,\omega_1 - \omega_1 = 0.5\,\omega_1 = 0.010935$

State 2: $\phi_2 = 100\%$, $\omega_2 = 0.010935$ => $P_{v2} = 100\,\dfrac{\omega_2}{0.622 + \omega_2} = 1.728$ kPa

$P_{v2} = P_{g2}$ => $T_2 =$ **15.2°C**; $h_f = 63.74$ kJ/kg

CV Cooler

$$\dot{Q} = 0.5\,\dot{m}_a\,(h_2 - h_1)_a + 0.5\,\dot{m}_a\,(\omega_2 h_{v2} - \omega_1 h_{v1}) + \dot{m}_{liq}\,h_f$$

$$= 0.5\,\dot{m}_a\,[C_{p\,a}\,(T_2 - T_1) + \omega_2 h_{v2} - \omega_1 h_{v1} + 2(\omega_1 - \omega_3)\,h_f\,]$$

$$= 0.5\,\frac{2}{1 + \omega_1}\ \text{kg/s}\ [\ 1.004\ (15.2 - 30) + 0.010935 \times 2529.3$$

$$- 0.02187 \times 2556.25 + 2 \times 0.25 \times 0.02187 \times 63.74\ ]\ \text{kJ/kg}$$

$$= \mathbf{-\ 41.5\ kW}$$

From the energy equation for the junction

$h_{a3} + \omega_3\,h_{v3} = 0.5\,[h_{a1} + \omega_1 h_{v1} + h_{a2} + \omega_2 h_{v2}] = 0.5[1.004\ (30 + 15.2)$

$+ 0.02187 \times 2556.25 + 0.010935 \times 2529.3] = 64.472$ kJ/kg

This is now trial and error on T_3.

$T_3 = 20$C: LHS $= 1.004 \times 20 + 0.016403 \times 2538.06 = 61.71$ kJ/kg

$T_3 = 25$C: LHS $= 1.004 \times 25 + 0.016403 \times 2547.17 = 66.88$ kJ/kg

Interpolate for final ans.: $T_3 =$ **22.7°C**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.96

A water-cooling tower for a power plant cools 45°C liquid water by evaporation. The tower receives air at 19.5°C, ϕ = 30%, 100 kPa that is blown through/over the water such that it leaves the tower at 25°C, ϕ = 70%. The remaining liquid water flows back to the condenser at 30°C having given off 1 MW. Find the mass flow rate of air, and the amount of water that evaporates.

Solution:

CV Total cooling tower, steady state.

Continuity Eq. for water in air: $w_{in} + \dot{m}_{evap}/\dot{m}_a = w_{ex}$

Energy Eq.: $\dot{m}_a \tilde{h}_{in} + \dot{m}_1 h_{45} = \dot{m}_a \tilde{h}_{ex} + (\dot{m}_1 - \dot{m}_{evap}) h_{30}$

Inlet: 19.5°C, 30% rel hum => $w_{in} = 0.0041$, $\tilde{h}_{in} = 50$ kJ/kg dry air

Exit : 25°C, 70% rel hum => $w_{ex} = 0.0138$, $\tilde{h}_{ex} = 80$ kJ/kg dry air

Take the two water flow difference to mean the 1 MW

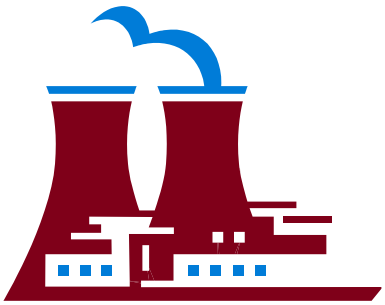
$$\dot{Q} = \dot{m}_1 h_{45} - (\dot{m}_1 - \dot{m}_{evap}) h_{30} = 1 \text{ MW}$$

Substitute this into the energy equation above and we get

$$\dot{m}_a(\tilde{h}_{ex} - \tilde{h}_{in}) = \dot{m}_a(80 - 50) = 1000 \text{ kW} \quad => \quad \dot{m}_a = \mathbf{33.33\ kg/s}$$

$$\dot{m}_{evap} = (w_{ex} - w_{in})\, \dot{m}_a = 0.0097 \times 33.33 = \mathbf{0.323\ kg/s}$$

The needed make-up water flow could be added to give a slightly different meaning to the 1 MW.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.97

Moist air at 31^{o}C and 50% relative humidity flows over a large surface of liquid water. Find the adiabatic saturation temperature by trial and error. Hint: it is around 22.5^{o}C.

For adiabatic saturation ($\Phi_2 = 1$ and assume P = 100 kPa), energy Eq.11.30

$$\omega_1 (h_{v1} - h_{f2}) = C_p(T_2 - T_1) + \omega_2 h_{fg2}$$

State 1: $$\omega_1 = 0.622 \times \frac{\Phi P_{g1}}{P_1 - \Phi P_{g1}} = 0.622 \times \frac{0.5 \times 4.5}{100 - 0.5 \times 4.5} = 0.01432$$

$$\phi_2 = 1 \quad \& \quad \omega_2 = 0.622 \times P_{g2}/(P_2 - P_{g2})$$

Only one unknown in energy Eq.: T_2 . Trial and error on energy equation:

$$C_pT_2 + \omega_2 h_{fg2} + \omega_1 h_{f2} = C_pT_1 + \omega_1 h_{v1}$$

$$= 1.004 \times 31 + 0.01432 \times 2558 = 67.7546 \text{ kJ/kg}$$

$T_2 = 20\ ^{o}$C: $P_{g2} = 2.339$ kPa, $h_{f2} = 83.94$ kJ/kg, $h_{fg2} = 2454.12$ kJ/kg

$$\Rightarrow \omega_2 = 0.622 \times 2.339/\ 97.661 = 0.0149$$

$$\text{LHS} = 1.004 \times 20 + 0.0149 \times 2454.12 + 0.01432 \times 83.94 = 57.848$$

$T_2 = 25\ ^{o}$C: $P_{g2} = 3.169$ kPa, $h_{f2} = 104.87$ kJ/kg, $h_{fg2} = 2442.3$ kJ/kg

$$\Rightarrow \omega_2 = 0.622 \times 3.169/\ 96.831 = 0.02036$$

$$\text{LHS} = 1.004 \times 25 + 0.02036 \times 2442.3 + 0.01432 \times 104.87 = 76.327$$

Linear interpolation to match RHS = 67.7546:

$$T_2 = 20 + (25 - 20) \frac{67.7546 - 57.848}{76.327 - 57.848} = \mathbf{22.7\ ^{o}C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.98

A flow of air at 10°C, $\phi = 90\%$, is brought into a house, where it is conditioned to 25°C, 60% relative humidity. This is done with a combined heater-evaporator where any liquid water is at 10°C. Find any flow of liquid, and the necessary heat transfer, both per kilogram dry air flowing. Find the dew point for the final mixture.

CV heater and evaporator. Use psychrometric chart.

Inlet: $\omega_1 = 0.0069$, $\tilde{h}_1 = 47$ kJ/kg dry air, $h_f = 41.99$ kJ/kg

Exit: $\omega_2 = 0.0118$, $\tilde{h}_2 = 75$ kJ/kg dry air, $\mathbf{T_{dew} = 16.5°C}$

From these numbers we see that water and heat must be added.

Continuity eq. for water

$$\dot{m}_{LIQ\ IN}/\dot{m}_A = \omega_2 - \omega_1 = \mathbf{0.0049\ kg/kg\ dry\ air}$$

Energy equation per kg dry air

$$\tilde{q} = \tilde{h}_2 - \tilde{h}_1 - (\omega_2 - \omega_1)\, h_f = \mathbf{27.8\ kJ/kg\ dry\ air}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.99

An air conditioner for an airport receives desert air at 45°C, 10% relative humidity and must deliver this to the buildings at 20°C, 50% relative humidity. They have a cooling system with R-410A running with high pressure of 3000 kPa and low pressure of 1000 kPa and their tap water is 18°C. What should be done to the air? Find the needed heating/cooling per kg dry air.

Check out the psychrometric chart:

State 1: $w_1 = 0.0056$, $\tilde{h}_1 = 79$; State 2: $w_2 = 0.0072$, $\tilde{h}_2 = 58$ kJ/kg

Liquid tap: $h_{liq} = 75.556$ kJ/kg from B.1.1

Now we know the following:

We must **add water** ($w_2 > w_1$) and then **cool** ($T_{wet\ 1} > 20^oC$)

Water continuity equation: $\dot{m}_{liq} = \dot{m}_{air}\,(w_2 - w_1)$

Energy equation: $\tilde{h}_1 + (w_2 - w_1)\, h_{liq} + \tilde{q} = \tilde{h}_2$

$$\tilde{q} = \tilde{h}_2 - \tilde{h}_1 - (w_2 - w_1)\, h_{liq}$$
$$= 58 - 79 - (0.0072 - 0.0056)\, 75.556$$
$$= -21.12 \text{ kJ/kg dry air}$$

For the refrigeration cycle we can find from table B.3.1

$P_{low} = 200$ kPa $\Rightarrow$ $T_{evaporator} = -12^oC$, which is cold enough

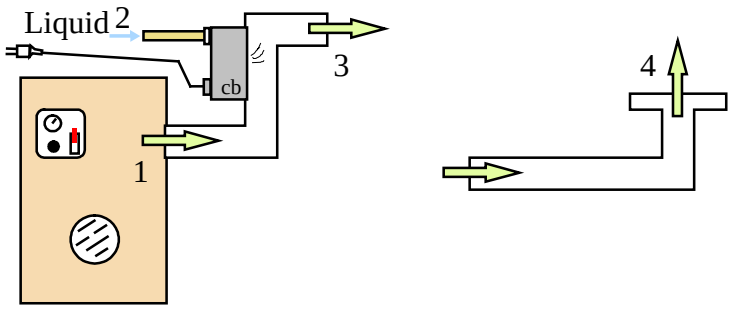
$P_{high} = 1500$ kPa $\Rightarrow$ $T_{condenser} = 59^oC > 45^oC$ so it is hot enough.

No absolute scaling was provided (the mass flow rates or $\dot{W}$) so we do not know if the motor/compressor combination is big enough.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.100

A flow of moist air from a domestic furnace, state 1, is at 45°C, 10% relative humidity with a flow rate of 0.05 kg/s dry air. A small electric heater adds steam at 100°C, 100 kPa generated from tap water at 15°C. Up in the living room the flow comes out at state 4: 30°C, 60% relative humidity. Find the power needed for the electric heater and the heat transfer to the flow from state 1 to state 4.



Properties from the psychrometric chart

State 1: $w_1 = 0.0056$, $\tilde{h}_1 = 79$ kJ/kg dry air

State 4: $w_4 = 0.0160$, $\tilde{h}_4 = 90.5$ kJ/kg dry air

Continuity equation for water from 1 to 4

$$\dot{m}_{liq} = \dot{m}_a (\omega_4 - \omega_1) = 0.05\ (0.016 - 0.0056) = 0.00052 \text{ kg/s}$$

Energy Eq. for heater:

$$\dot{Q}_{heater} = \dot{m}_{liq} (h_{out} - h_{in}) = 0.00052\ (2676.05 - 62.98) = \mathbf{1.36\ kW}$$

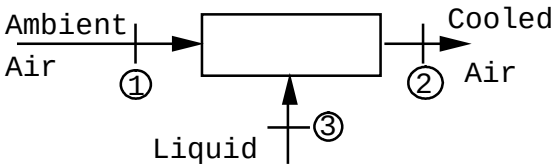
Energy Eq. for line:

$$\begin{aligned} \dot{Q}_{line} &= \dot{m}_a (\tilde{h}_4 - \tilde{h}_1) - \dot{m}_{liq}\, h_{vap} \\ &= 0.05(90.5 - 79) - 0.00052 \times 2676.05 \\ &= \mathbf{-0.816\ kW} \end{aligned}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.101

One means of air-conditioning hot summer air is by evaporative cooling, which is a process similar to the adiabatic saturation process. Consider outdoor ambient air at 35°C, 100 kPa, 30% relative humidity. What is the maximum amount of cooling that can be achieved by such a technique? What disadvantage is there to this approach? Solve the problem using a first law analysis and repeat it using the psychrometric chart, Fig. E.4.



$P_1 = P_2 = 100$ kPa

$P_{v1} = \phi_1 P_{g1} = 0.30 \times 5.628 = 1.6884$

$\omega_1 = 0.622 \times 1.6884/98.31 = 0.01068$

For adiabatic saturation (Max. cooling is for $\phi_2 = 1$),

Energy Eq. Eq.11.30: $\omega_1 (h_{v1} - h_{f2}) = C_p(T_2 - T_1) + \omega_2 h_{fg2}$

$\phi_2 = 1$ & $\omega_2 = 0.622 \times P_{G2}/(P_2 - P_{G2})$

Only one unknown: T_2 . Trial and error on energy equation:

$$C_pT_2 + \omega_2 h_{fg2} + \omega_1 h_{f2} = C_pT_1 + \omega_1 h_{v1}$$

$$= 1.004 \times 35 + 0.01068 \times 2565.3 = 62.537 \text{ kJ/kg}$$

$T_2 = 20\ ^oC$: $P_{G2} = 2.339$ kPa, $h_{f2} = 83.94$, $h_{fg2} = 2454.12$ kJ/kg

=> $\omega_2 = 0.622 \times 2.339/ 97.661 = 0.0149$

LHS = $1.004 \times 20 + 0.0149 \times 2454.1 + 0.01068 \times 83.94 = 57.543$ kJ/kg

$T_2 = 25\ ^oC$: $P_{G2} = 3.169$ kPa, $h_{f2} = 104.87$, $h_{fg2} = 2442.3$ kJ/kg

=> $\omega_2 = 0.622 \times 3.169/ 96.831 = 0.02036$

LHS = $1.004 \times 25 + 0.02036 \times 2442.3 + 0.01068 \times 104.87 = 75.945$ kJ/kg

linear interpolation: $T_2 =$ **21.4 °C**

This method lowers the temperature but the relative and absolute humidity becomes very high and the slightest cooling like on a wall results in condensation.

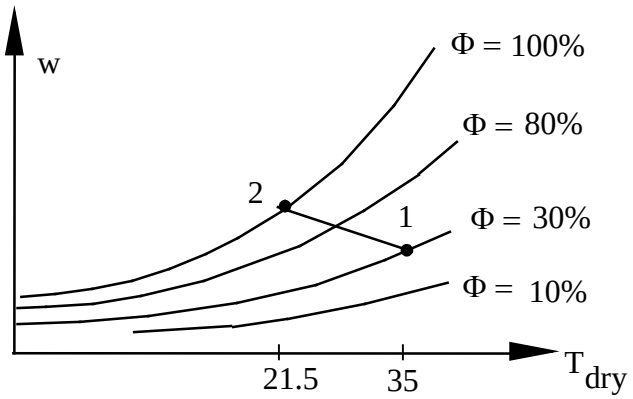
Solution 11.101 Continued.

b) chart E.4 : Adiabatic saturation $T_2 \approx$ WetBulbTemperature $\approx$ **21.5 °C**

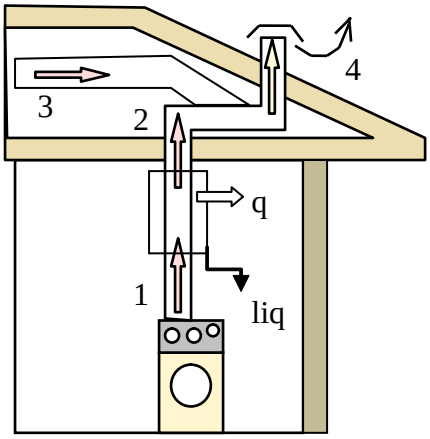


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.102

A flow out of a clothes dryer of 0.05 kg/s dry air is at 40°C and relative humidity 60%. It flows through a heat exchanger where it exits at 20°C. After heat exchanger the flow combines with another flow of 0.03 kg/s dry air at 30°C and relative humidity 30%. Find the dew point of state 1, see Fig. P11.102, the heat transfer per kg dry air and the final exit state humidity ratio and relative humidity.

Use the psychrometric chart to solve the problem.



State 1: $w = 0.0286$, $\tilde{h}_1 = 131.5$, $T_{dew} = 31^oC$

State 2: $20^oC < T_{dew}$ so it is saturated.

$w_2 = 0.0148$, $\tilde{h}_2 = 77.8$ kJ/kg air

State 3: $w_3 = 0.0078$, $\tilde{h}_3 = 69.8$ kJ/kg air,

$$\dot{m}_{liq}/\dot{m}_a = \omega_1 - \omega_2 = 0.0138 \text{ kg/kg dry air}$$

Energy Eq.:

$$\dot{Q}/\dot{m}_a = \tilde{h}_1 - \tilde{h}_2 - (\omega_1 - \omega_2)\, h_f$$
$$= 131.5 - 77.8 - 0.0138 \times 83.94$$
$$= 52.5 \text{ kJ/kg dry air}$$

Do CV around the junction where flow 2 and 3 combines to give exit at 4.

Continuity water: $\dot{m}_{a1}\,\omega_2 + \dot{m}_{a3}\,\omega_3 = \dot{m}_{a4}\,\omega_4$

$$\omega_4 = (\dot{m}_{a1}/\dot{m}_{a4})\,\omega_2 + (\dot{m}_{a3}/\dot{m}_{a4})\,\omega_3$$
$$= \frac{0.05}{0.08} \times 0.0148 + \frac{0.03}{0.08} \times 0.0078 = 0.012175$$

Energy Equation: $\dot{m}_{a1}\,\tilde{h}_2 + \dot{m}_{a3}\,\tilde{h}_3 = \dot{m}_{a4}\,\tilde{h}_4$

$$\tilde{h}_4 = (\dot{m}_{a1}/\dot{m}_{a4})\,\tilde{h}_2 + (\dot{m}_{a3}/\dot{m}_{a4})\,\tilde{h}_3$$
$$= \frac{0.05}{0.08} \times 77.8 + \frac{0.03}{0.08} \times 69.8 = 74.8 \text{ kJ/kg air}$$

From chart given $(\omega_4, \tilde{h}_4)$ we get: $\Phi_4 = 65\%$ and $T_4 = 24^oC$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.103

Atmospheric air at 35°C, relative humidity of 10%, is too warm and also too dry. An air conditioner should deliver air at 21°C and 50% relative humidity in the amount of 3600 m^3 per hour. Sketch a setup to accomplish this, find any amount of liquid (at 20°C) that is needed or discarded and any heat transfer.

CV air conditioner. First we must check if water should be added or subtracted. We can know this from the absolute humidity ratio.

Properties from the tables and formulas

State 1: $P_{g35} = 5.628$ kPa ; $P_{v1} = 0.10 \times 5.628$ kPa = 0.5628 kPa

$w_1 = 0.622 \times 0.5628 / (101.325 - 0.5628) = 0.003474$

State 2: $P_{g21} = 2.505$ kPa; $P_{v2} = 0.5 \times 2.505$ kPa = 1.253 kPa

$w_2 = 0.622 \times 1.253 / (101.325 - 1.253) = 0.007785$

As w goes up we must add liquid water. Now we get

Continuity Eq.: $\dot{m}_{air}(1 + w_1) + \dot{m}_{liq} = \dot{m}_{air}(1 + w_2)$

Energy Eq.: $\dot{m}_{air}\tilde{h}_1 + \dot{m}_{liq}h_f + \dot{Q}_{CV} = \dot{m}_{air}\tilde{h}_2$

For the liquid flow we need the air mass flowrate out, 3600 m^3/h = 1 m^3/s

$\dot{m}_{air} = P_{a\,2}\dot{V}/RT = (101.325 - 1.253)1/0.287 \times 294.15 = 1.185$ kg/s

$\dot{m}_{liq} = \dot{m}_{air}(w_2 - w_1) = 0.00511$ kg/s = **18.4 kg/h**

$\dot{Q}_{CV} = \dot{m}_{air}[C_{p\,a}(T_2 - T_1) + w_2 h_{v2} - w_1 h_{v1}] - \dot{m}_{liq}h_f$

$= 1.185 [\ 1.004\ (21 - 35) + 0.007785 \times 2539.9 - 0.003474 \times 2565.3]$

$- 0.00511 \times 83.96 =$ **- 4.21 kW**

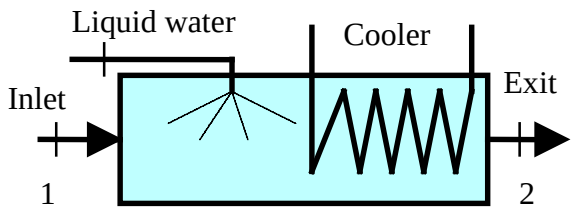
If from psychrometric chart.

Inlet: $w_1 = 0.0030$, $\tilde{h}_1 = 63.0$, $h_{f,20} = 83.96$ kJ/kg

Exit: $w_2 = 0.0076$, $\tilde{h}_2 = 60.2$ kJ/kg dry air, P_{v2} , $\dot{m}_{air}$ same as above

$\dot{Q}_{CV} = \dot{m}_{air}(\tilde{h}_2 - \tilde{h}_1) - \dot{m}_{liq}h_f = 1.185(60.2 - 63) - 0.00511 \times 83.96$

$= - 3.74$ kW



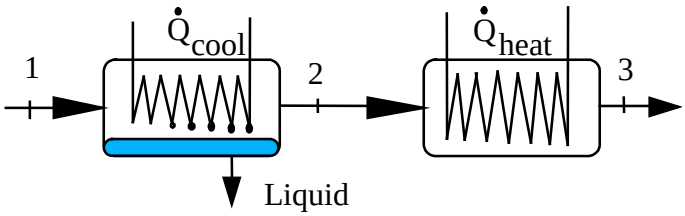
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

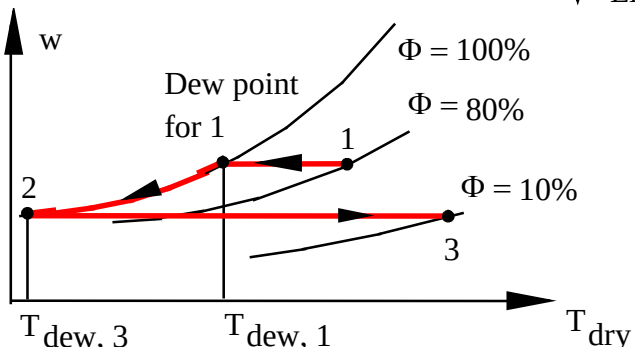
11.104

In a car's defrost/defog system atmospheric air, 21°C, relative humidity 80%, is taken in and cooled such that liquid water drips out. The now dryer air is heated to 41°C and then blown onto the windshield, where it should have a maximum of 10% relative humidity to remove water from the windshield. Find the dew point of the atmospheric air, specific humidity of air onto the windshield, the lowest temperature and the specific heat transfer in the cooler.

Solution:

Solve using the psychrometric chart





Air inlet: 21°C, ϕ = 80%
=> $w_1 = 0.0124$,
T_{dew} = **17.3°C**
$\tilde{h}_1 = 72$

Air exit: 41°C, ϕ = 10%
=> w_3 = **0.0044**,
T_{dew} = **1.9°C**

To remove enough water we must cool to the exit T_{dew}, followed by heating to T_{ex}. The enthalpy from chart $\tilde{h}_2 = 32.5$ and from B.1.1, $h_f(1.9°C) = 8$ kJ/kg

CV cooler:

$$\dot{m}_{liq}/\dot{m}_{air} = w_1 - w_3 = 0.0124 - 0.0044 = 0.008 \text{ kg liq/kg air}$$

$$q = \dot{Q}_{CV}/\dot{m}_{air} = \tilde{h}_2 + (w_1 - w_3)\, h_f - \tilde{h}_1$$

$$= 32.5 + 0.008 \times 8 - 72 = \textbf{-39.4 kJ/kg dry air}$$

If the steam and air tables are used the numbers are

State 1: $P_{g1} = 2.505$ kPa, $P_{v1} = 2.004$ kPa => $w_1 = 0.01259$

$h_{g1} = 2539.9$, $h_{a1} = 294.3$ => $\tilde{h}_1 = 326.3$ kJ/kg

State 3: $P_{g3} = 7.826$, $P_{v3} = 0.783$ => w_3 = **0.00486**

State 2: $w_{g3} = w_3$ => $T_2 = T_{3dew} = 3.3°C$, $h_{f2} = 13.77$ kJ/kg

$h_{g2} = 2507.4$, $h_{a2} = 276.56$ => $\tilde{h}_2 = 288.75$ kJ/kg

$\dot{m}_{liq}/\dot{m}_{air} = 0.00773$, $q = 288.75 + 0.00773 \times 13.77 - 326.3$ = **-37.45 kJ/kg air**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.105

A commercial laundry runs a dryer that has an exit flow of 0.5 kg/s moist air at 48 °C, 70% relative humidity. To save on the heating cost a counterflow **stack heat exchanger** is used to heat a cold water line at 10°C for the washers with the exit flow, as shown in Fig. P11.105. Assume the outgoing flow can be cooled to 25°C. Is there a missing flow in the figure? Find the rate of energy recovered by this heat exchanger and the amount of cold water that can be heated to 30°C.

The flow out of the dryer is outside the range for the psychrometric chart so the solution is done with the tables and the formula's.

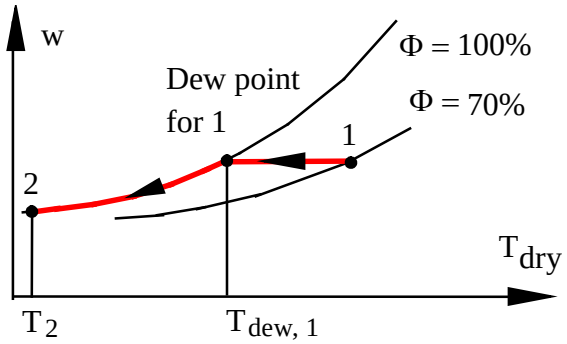
Dryer oulet, 1: 48°C, Φ = 70%

=> h_{g1} = 2588.51 kJ/kg

P_{g1} = 11.247 kPa,

$P_{v1} = 0.7 \times 11.247$ kPa = 7.873 kPa

$$\omega_1 = \frac{0.622 \times 7.873}{101.325 - 7.873} = 0.05241$$



State 2: $T_2 < T_{dew\,1} \approx 42^oC$ so $\Phi_2 = 100\%$. P_{g2} = 3.169 kPa, h_{g2} = 2547.17 kJ/kg,

h_{f2} = 104.87 kJ/kg, $\omega_2 = 0.622 \times 3.169/(101.325 - 3.169) = 0.02008$

Continuity Eq. water 1-2 line: $\dot{m}_a \omega_1 = \dot{m}_a \omega_2 + \dot{m}_{liq}$; $\dot{m}_{liq} = \dot{m}_a(\omega_1 - \omega_2)$

The mass flow rate of dry air is

$$\dot{m}_a = \dot{m}_{moist\ air}/(1 + \omega_1) = 0.5\ kg/s\ /(1 + 0.05241) = 0.4751\ kg/s$$

The heat out of the exhaust air which also equals the energy recovered becomes

$$\dot{Q}_{CV} = \dot{m}_a [\, C_{p\,a}(T_1 - T_2) + \omega_1 h_{g1} - (\omega_1 - \omega_2) h_{f2} - \omega_2 h_{g2}\,]$$

$$= 0.4751\,[1.004(48 - 25) + 0.05241 \times 2588.51 - 0.03233 \times 104.87$$

$$- \quad 0.02008 \times 2547.17]$$

$$= 0.4751\ kg/s \times 104.2\ kJ/kg = \mathbf{49.51\ kW}$$

$$\dot{m}_{liq} = \dot{Q}_{CV} / (\, C_{P\,liq}\, \Delta T_{liq}) = 49.51 / [4.18\,(30 - 10)] = \mathbf{0.592\ kg/s}$$

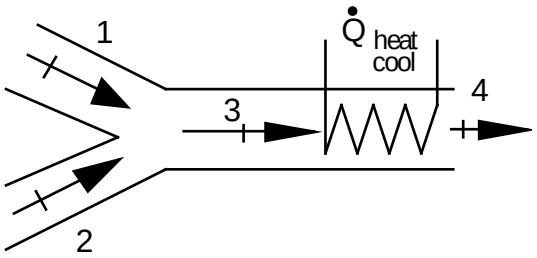
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.106

A flow of moist air at 45°C, 10% relative humidity with a flow rate of 0.2 kg/s dry air is mixed with a flow of moist air at 25°C, and absolute humidity of w = 0.018 with a rate of 0.3 kg/s dry air. The mixing takes place in an air duct at 100 kPa and there is no significant heat transfer. After the mixing there is heat transfer to a final temperature of 25°C. Find the temperature and relative humidity after mixing. Find the heat transfer and the final exit relative humidity.

Solution:

C.V : Total Setup
state 3 is internal to CV.



Continuity Eq.: $\dot{m}_{a1}\, w_1 + \dot{m}_{a2}\, w_2 = (\dot{m}_{a1} + \dot{m}_{a2})\, w_3 = (\dot{m}_{a1} + \dot{m}_{a2})\, w_4$

Energy Eq. $\dot{m}_{a1}\, \tilde{h}_1 + \dot{m}_{a2}\, \tilde{h}_2 = (\dot{m}_{a1} + \dot{m}_{a2})\, \tilde{h}_3$

State 1: From Psychrometric chart $w_1 = 0.0056$, $\tilde{h}_1 = 79$ kJ/kg dry air

State 2: From Psychrometric chart $\Phi_2 = 90\%$, $\tilde{h}_2 = 90.5$ kJ/kg dry air

$$w_3 = w_4 = \frac{\dot{m}_{a1} w_1 + \dot{m}_{a2} w_2}{\dot{m}_{a1} + \dot{m}_{a2}} = \frac{0.2}{0.5}\, 0.0056 + \frac{0.3}{0.5}\, 0.018 = 0.01304$$

$$\tilde{h}_3 = \frac{\dot{m}_{a1} \tilde{h}_1 + \dot{m}_{a2} \tilde{h}_2}{\dot{m}_{a1} + \dot{m}_{a2}} = \frac{0.2}{0.5} \times 79 + \frac{0.3}{0.5} \times 90.5 = 85.9 \text{ kJ/kg dry air}$$

State 3: From Psychrometric chart $T_3 = 32.5°C$, $\Phi_3 = 45\%$

State 4: 25°C, $w_4 = 0.01304$ Read from Psychrometric chart

$\tilde{h}_4 = 78$, $\quad \mathbf{\Phi_4 = 66\%}$

Now do the energy equation for the whole setup

Energy Eq. $\dot{m}_{a1}\, \tilde{h}_1 + \dot{m}_{a2}\, \tilde{h}_2 + \dot{Q} = (\dot{m}_{a1} + \dot{m}_{a2})\, \tilde{h}_4$

$$\dot{Q} = (\dot{m}_{a1} + \dot{m}_{a2})\, \tilde{h}_4 - \dot{m}_{a1}\, \tilde{h}_1 + \dot{m}_{a2}\, \tilde{h}_2$$
$$= 0.5 \times 78 - 0.2 \times 79 - 0.3 \times 90.5 = \mathbf{-3.95\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.107

An indoor pool evaporates 1.512 kg/h of water, which is removed by a dehumidifier to maintain 21°C, ϕ = 70% in the room. The dehumidifier, shown in Fig. P11.107, is a refrigeration cycle in which air flowing over the evaporator cools such that liquid water drops out, and the air continues flowing over the condenser. For an air flow rate of 0.1 kg/s the unit requires 1.4 kW input to a motor driving a fan and the compressor and it has a coefficient of performance, $\beta = Q_L/W_c = 2.0$. Find the state of the air as it returns to the room and the compressor work input.

Solution:

The unit must remove 1.512 kg/h liquid to keep steady state in the room. As water condenses out state 2 is saturated.

State 1: 21°C, 70% => $w_1 = 0.0108$, $\tilde{h}_1 = 68.5$

CV 1 to 2: $\dot{m}_{liq} = \dot{m}_a(w_1 - w_2)$ => $w_2 = w_1 - \dot{m}_{liq}/\dot{m}_a$

$$q_L = \tilde{h}_1 - \tilde{h}_2 - (w_1 - w_2)\, h_{f2}$$

$$w_2 = 0.0108 - 1.512/3600 \times 0.1 = 0.0066$$

State 2: w_2, 100% => $T_2 = 8°C$, $\tilde{h}_2 = 45$, $h_{f2} = 33.6$

$$q_L = 68.5 - 45 - 0.0042 \times 33.6 = 23.36 \text{ kJ/kg dry air}$$

CV Total system : $\tilde{h}_3 = \tilde{h}_1 + \dot{W}_{el}/\dot{m}_a - (w_1 - w_2)\, h_f$

$$= 68.5 + 14 - 0.14 = 82.36 \text{ kJ/kg dry air}$$

State 3: $w_3 = w_2$, $\tilde{h}_3$ => $T_3 =$ **46°C,** $\phi_3 =$ **11-12%**

$$\dot{W}_c = \dot{m}_a\, q_L/\beta = \mathbf{1.165\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.108

A moist air flow of 5 kg/min at 30°C, Φ = 60%, 100 kPa goes through a dehumidifier in a setup shown in Problem 11.107. The air is cooled down to 15°C and then blown over the condenser. The refrigeration cycle runs with R-134a with a low pressure of 200 kPa and a high pressure of 1000 kPa. Find the COP of the refrigeration cycle, the ratio $\dot{m}_{R\text{-}134a}/\dot{m}_{air}$ and the outgoing T_3 and Φ_3.

Standard Refrigeration Cycle

Table B.5: $h_1 = 392.15$ kJ/kg; $s_1 = 1.732$ kJ/kg K; $h_4 = h_3 = 255.56$ kJ/kg

C.V. Compressor (assume ideal)

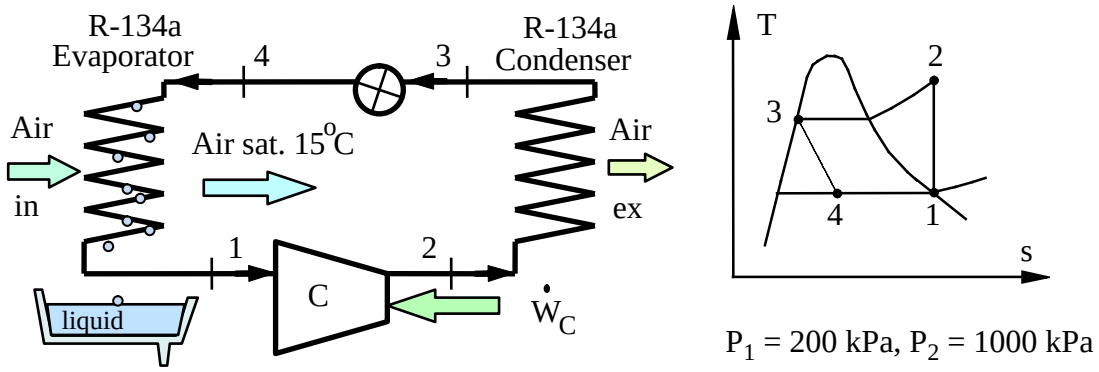
$\dot{m}_1 = \dot{m}_2$ $\quad w_C = h_2 - h_1$; $\quad s_2 = s_1 + s_{gen}$

$P_2, s = s_1 \Rightarrow h_2 = 425.71$ kJ/kg $\Rightarrow w_C = 33.56$ kJ/kg

C.V. Evaporator: $q_L = h_1 - h_4 = 392.15 - 255.56 = 136.59$ kJ/kg

C.V. Condenser: $q_H = h_2 - h_3 = 425.71 - 255.56 = 170.15$ kJ/kg

$$\text{COP} = \beta = q_L / w_C = \frac{136.59}{33.56} = 4.07$$



$P_1 = 200$ kPa, $P_2 = 1000$ kPa

For the air processes let us use the psychrometric chart.

Air inlet: $w_{in} = 0.016$, $\tilde{h}_{in} = 90.5$ kJ/kg dry air, $T_{dew} = 21°C > 15°C$

Air 15°C: $\phi = 100\%$, $w_7 = 0.0107$, $\tilde{h}_7 = 62$, $h_f = 62.98$ (B.1.1)

Now do the continuity (for water) and energy equations for the cooling process

$\dot{m}_{liq}/\dot{m}_{air} = w_{in} - w_7 = 0.016 - 0.0107 = 0.0053$ kg/kg air

$q_{cool} = \tilde{h}_{in} - \tilde{h}_7 - \dot{m}_{liq}h_f/\dot{m}_{air} = 90.5 - 62 - 0.0053 \times 62.98 = 28.17$ kJ/kg air

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Solution 11.108 continued

Now the cooling of the air is done by the R-134a so

$$\dot{Q}_{cool} = \dot{m}_{air}\, q_{cool} = \dot{m}_{R134a}\, q_L \quad \Rightarrow \quad \dot{m}_{R134a}/\dot{m}_{air} = \frac{q_{cool}}{q_L} = \frac{28.17}{136.59} = \mathbf{0.2062}$$

Energy eq. for the air flow being heated

$$\dot{Q}_{heat} = \dot{m}_{air}(\tilde{h}_{ex} - \tilde{h}_7) \quad \Rightarrow \quad \tilde{h}_{ex} = \tilde{h}_7 + \dot{Q}_{heat} / \dot{m}_{air} = \tilde{h}_7 + q_H \times \dot{m}_{R134a}/\dot{m}_{air}$$

$$\tilde{h}_{ex} = 62 + 170.15 \times 0.2062 = 97.08 \text{ kJ/kg dry air} \quad \text{and} \quad w_{ex} = w_7$$

Locate state in the psychrometric chart [just outside edge of chart]

$$T_{ex} = 49.3^{o}C \quad \text{and} \quad \phi_{ex} = 15\%$$

11.109

Use the psychrometric chart to find the missing property of: ϕ, ω, T_{wet}, T_{dry}

a. T_{dry} = 25°C, ϕ =80% b. T_{dry} =15°C, ϕ =100%

c. T_{dry} = 20°C, and ω = 0.010 d. T_{dry} = 25°C, T_{wet} = 23°C

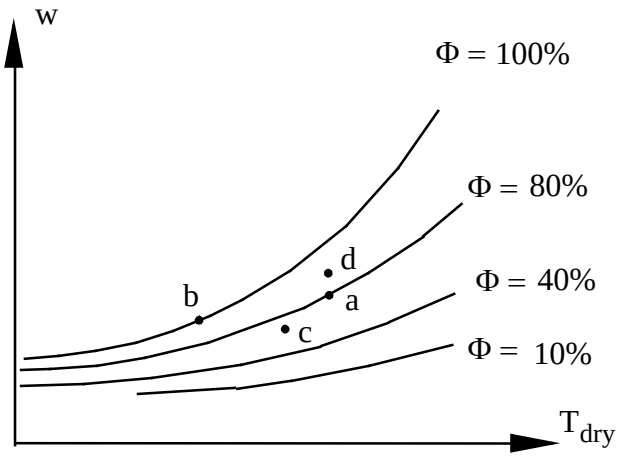
Solution:

a. 25°C, ϕ = 80% => ω = 0.016; T_{wet} = 22.3°C

b. 15°C, ϕ = 100% => ω = 0.0106; T_{wet} = 15°C

c. 20°C, ω = 0.010 => ϕ = 70%; T_{wet} = 16.3°C

d. 25°C, T_{wet} = 23°C => ω = 0.017; ϕ = 86%



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.110

Use the psychrometric chart to find the missing property of: ϕ, ω, T_{wet}, T_{dry}

a. $\phi = 50\%$, $\omega = 0.014$ b. $T_{wet} = 15°C$, $\phi = 60\%$.

c. $\omega = 0.008$ and $T_{wet} = 15°C$ d. $T_{dry} = 10°C$, $\omega = 0.006$

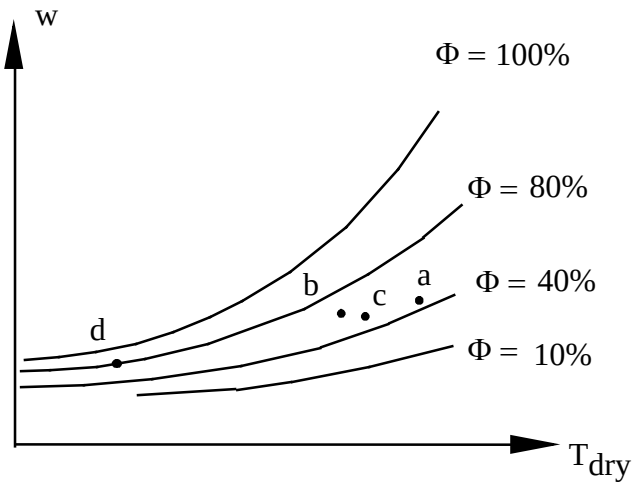
Solution:

a. $\phi = 50\%$, $\omega = 0.014$ => $T_{dry} = 31°C$, $T_{wet} = 22.6\ °C$

b. $T_{wet} = 15°C$, $\phi = 60\%$ => $T_{dry} = 20.2°C$, $\omega = 0.0086$

c. $\omega = 0.008$, $T_{wet} = 15°C$ => $T_{dry} = 21.8°C$, $\phi = 50\%$

d. $T_{dry} = 10°C$, $\omega = 0.006$ => $\phi = 80\%$, $T_{wet} = 8.2°C$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.111

For each of the states in Problem 11.110 find the dew point temperature.

Solution:

The dew point is the state with the same humidity ratio (abs humidity ω) and completely saturated $\phi = 100\%$. From psychrometric chart:

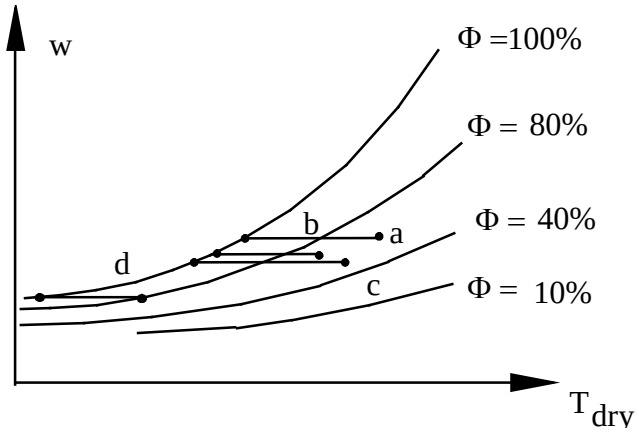
a. $T_{dew} = 19.2°C$ c. $T_{dew} = 10.8°C$

b. $T_{dew} = 12°C$ d. $T_{dew} = 6.5°C$

Finding the solution from the tables is done for cases a,c and d as

Eq.11.28 solve: $P_v = P_g = \omega P_{tot} / [\omega + 0.622] = P_g (T_{dew})$ in B.1.1

For case b use energy Eq. 13.30 to find ω_1 first from $T_{ad\ sat} = T_{wet}$.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.112

Use the formulas and the steam tables to find the missing property of: ϕ, ω, and T_{dry}, total pressure is 100 kPa; repeat the answers using the psychrometric chart
a. $\phi = 50\%$, $\omega = 0.010$ b. $T_{wet} = 15°C$, $\phi = 50\%$ c. $T_{dry} = 25°C$, $T_{wet} = 21°C$

a. From Eq.11.28 with $P_a = P - P_v$ solve for P_v:

$$P_v = P\,\omega/(0.622 + \omega) = 100 \times 0.01/0.632 = 1.582 \text{ kPa}$$

From Eq.11.25: $P_g = P_v/\phi = 1.582/0.5 = 3.165$ kPa => $T = 25°C$

b. Assume T_{wet} is adiabatic saturation T and use energy Eq.11.30

At 15°C: $P_g = 1.705$ kPa => $\omega = 0.622 \times \dfrac{1.705}{100 - 1.705} = 0.01079$

$LHS = \omega_1 (h_{v1} - h_{f2}) + C_p T_1 = RHS = C_p T_2 + \omega_2 h_{fg2}$

$RHS = 1.004 \times 15 + 0.01079 \times 2465.93 = 41.667$ kJ/kg

$\omega_1 = 0.622\,\phi P_g/(100 - \phi P_g)$ where P_g is at T_1. Trial and error.

$LHS_{25C} = 49.98$, $LHS_{20C} = 38.3$ => $T = 21.4°C$, $\omega_1 = 0.008$

c. At 21°C: $P_g = 2.505$ kPa => $\omega_2 = 0.622 \times \dfrac{2.505}{100 - 2.505} = 0.016$

$h_{f2} = 88.126$ and $h_{fg2} = 2451.76$ kJ/kg, $h_{v1} = 2547.17$ kJ/kg

From Eq.11.30: $\omega_1 = [C_p(T_2 - T_1) + \omega_2 h_{fg2}]/(h_{v1} - h_{f2}) = 0.0143$

$P_v = P\,\omega/(0.622 + \omega) = 2.247$, $\phi = 2.247/3.169 = 0.71$

Using the psychrometric chart E.4:

a: $T_{dry} = 25.3$ °C b. $T_{dry} = 21.6°C$, $\omega = 0.008$

c: $\omega = 0.0141$, $\phi = 71$-72%

11.113

An air-conditioner should cool a flow of ambient moist air at 40°C, 40% relative humidity with 0.2 kg/s flow of dry air. The exit temperature should be 20°C and the pressure is 100 kPa. Find the rate of heat transfer needed and check for the formation of liquid water.

Solution:

Before we know if we should have a liquid water flow term we need to check for condensation (the dew point).

Using the psychrometric chart. i: $\omega_i = 0.018$, $\tilde{h}_i = 106$ kJ/kg air, $T_{dew} = 23°C$

Since $T_{dew} > T_e$ then **condensation** occurs and the exit is $\phi = 100\%$

Exit state: 20°C, $\tilde{h}_e = 77.5$ kJ/kg air, $\omega_e = 0.0148$, $h_f = 83.94$ kJ/kg

CV heat exchanger:

Water: $\dot{m}_a \omega_i = \dot{m}_{liq} + \dot{m}_a \omega_e \quad \Rightarrow \quad \dot{m}_{liq} = \dot{m}_a (\omega_i - \omega_e)$

Energy: $(h_a + \omega h_v)_i + \tilde{q} = (h_a + \omega h_v)_e + (\omega_i - \omega_e) h_f,$

$$\tilde{q} = \tilde{h}_e - \tilde{h}_i + (\omega_i - \omega_e) h_f = 77.5 - 106 + (0.018 - 0.0148)\, 83.94$$

$$= -28.23 \text{ kJ/kg dry air}$$

$$\dot{Q} = \dot{m}_a \tilde{q} = 0.2 \text{ kg/s} \times (-28.23 \text{ kJ/kg}) = -\mathbf{5.65\ kW} \quad \text{(it goes out)}$$

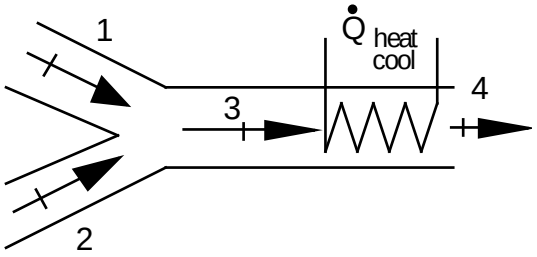
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.114

A flow of moist air at 21°C, 60% relative humidity should be produced from mixing of two different moist air flows. Flow 1 is at 10°C, relative humidity 80% and flow 2 is at 32°C and has T_{wet} = 27°C. The mixing chamber can be followed by a heater or a cooler. No liquid water is added and P = 100 kPa. Find the two controls one is the ratio of the two mass flow rates $\dot{m}_{a1}/\dot{m}_{a2}$ and the other is the heat transfer in the heater/cooler per kg dry air.

Solution:

C.V : Total Setup
state 3 is internal to CV.



Continuity Eq.: $\dot{m}_{a1}\, w_1 + \dot{m}_{a2}\, w_2 = (\dot{m}_{a1} + \dot{m}_{a2})\, w_4$

Energy Eq. $\dot{m}_{a1}\, \tilde{h}_1 + \dot{m}_{a2}\, \tilde{h}_2 + \dot{Q}_{a1} = (\dot{m}_{a1} + \dot{m}_{a2})\, \tilde{h}_4$

Define $x = \dot{m}_{a1}/\dot{m}_{a2}$ and substitute into continuity equation

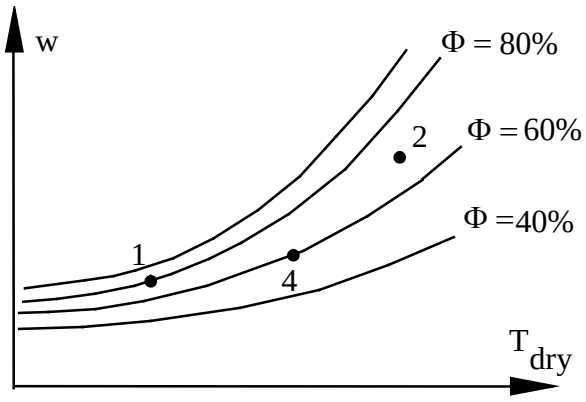
$$\Rightarrow \quad x\, w_1 + w_2 = (1+x)\, w_4 \quad \Rightarrow \quad x = \frac{w_4 - w_2}{w_1 - w_4} = \mathbf{3.773}$$

Energy equation scaled to total flow of dry air

$$\tilde{q} = \dot{Q}_{a1}/(\dot{m}_{a1} + \dot{m}_{a2}) = \tilde{h}_4 - [x/(1+x)]\, \tilde{h}_1 - [1/(1+x)]\, \tilde{h}_2$$

$$= 64 - 0.7905 \times 45 - 0.2095 \times 105$$

$$= \mathbf{6.43\ kJ/kg\text{-}dry\ air}$$



State 1:
$w_1 = 0.006$, $\tilde{h}_1 = 45$

State 2:
$w_2 = 0.0208$, $\tilde{h}_2 = 105$

State 4:
$w_4 = 0.0091$, $\tilde{h}_4 = 64$,
$T_{dew\,4} = 12.5$°C

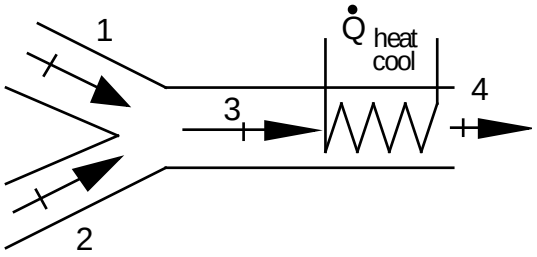
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.115

Consider a mixing process as in Fig. P11.114 where flow 1 comes in as cold and moist, 10°C, ϕ = 90%. It is mixed with a flow 2 at 42°C, T_{wet} = 31°C. If the exit flow should be at 21°C, ϕ = 50% find the ratio $\dot{m}_{a1}/\dot{m}_{a2}$ and the heat transfer per kg dry air out.

C.V : Total Setup
state 3 is internal to CV.

Assume no liquid flow then the balance equations are



Continuity Eq.: $\dot{m}_{a1}\, w_1 + \dot{m}_{a2}\, w_2 = (\dot{m}_{a1} + \dot{m}_{a2})\, w_4$

Energy Eq. $\dot{m}_{a1}\, \tilde{h}_1 + \dot{m}_{a2}\, \tilde{h}_2 + \dot{Q} = (\dot{m}_{a1} + \dot{m}_{a2})\, \tilde{h}_4$

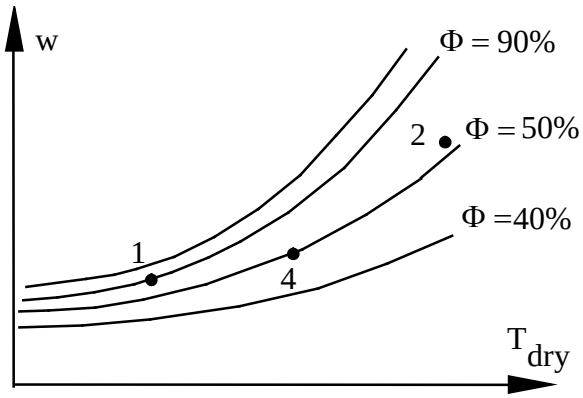
The continuity equation is solved for the ratio $x = \dot{m}_{a1}/\dot{m}_{a2}$

$$x = \dot{m}_{a1}/\dot{m}_{a2} = \frac{w_2 - w_4}{w_4 - w_1} = \frac{0.0245 - 0.0076}{0.0076 - 0.0067} = 18.7778$$

Then solve the energy eq. for the heat transfer

$$\dot{Q}/\dot{m}_{a4} = \tilde{h}_4 - \frac{x}{1+x}\tilde{h}_1 - \frac{1}{1+x}\tilde{h}_2 = 60 - \frac{18.7778}{19.7778}47 - \frac{1}{19.7778}124$$

= **9.107 kJ/kg air out**



State 1:
$w_1 = 0.0067$, $\tilde{h}_1 = 47$

State 2:
$w_2 = 0.0245$, $\tilde{h}_2 = 124$

State 4:
$w_4 = 0.0076$, $\tilde{h}_4 = 60$,

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.116

In a hot and dry climate, air enters an air-conditioner unit at 100 kPa, 40°C, and 5% relative humidity, at the steady rate of 1.0 m^3/s. Liquid water at 20°C is sprayed into the air in the AC unit at the rate 20 kg/hour, and heat is rejected from the unit at at the rate 20 kW. The exit pressure is 100 kPa. What are the exit temperature and relative humidity?

State 1: $T_1 = 40°C$, $P_1 = 100$ kPa, $\phi_1 = 5\%$, $\dot{V}_{a1} = 1\ m^3/s$

$P_{g1} = 7.3837$ kPa, $P_{v1} = \phi_1 P_{g1} = 0.369$ kPa, $P_{a1} = P - P_{v1} = 99.63$ kPa

$$\omega_1 = 0.622 \frac{P_{v1}}{P_{a1}} = 0.0023, \quad \dot{m}_{a1} = \frac{P_{a1}\dot{V}_{a1}}{RT_{a1}} = 1.108 \text{ kg/s}, \quad h_{v1} = 2574.3 \text{ kJ/kg}$$

State 2 : Liq. Water. 20°C, $\dot{m}_{f2} = 20$ kg/hr $= 0.00556$ kg/s, $h_{f2} = 83.9$ kJ/kg

Conservation of Mass: $\dot{m}_{a1} = \dot{m}_{a3}$, $\dot{m}_{v1} + \dot{m}_{12} = \dot{m}_{v3}$

$$\omega_3 = (\dot{m}_{f2} / \dot{m}_{a1}) + \omega_1 = (0.00556/1.108) + 0.0023 = 0.0073$$

State 3 : $P_3 = 100$ kPa and $P_{v3} = P_3\omega_3/(0.622 + \omega_3) = 1.16$ kPa

Energy Eq. with $\dot{Q} = -20$ kW :

$$\dot{Q} + \dot{m}_{a1}h_{a1} + \dot{m}_{v1}h_{v1} + \dot{m}_{f2}h_{f2} = \dot{m}_{a3}h_{a3} + \dot{m}_{v3}h_{v3};$$

$$(h_{a3}-h_{a1}) + \omega_3 h_{v3} = \omega_1 h_{v1} + (\dot{m}_{f2}h_{f2} + \dot{Q})/\dot{m}_{a1}$$

$$= 0.0023 \times 2574.3 + (0.00556 \times 83.9 - 20)/1.108 = -11.7$$

Unknowns: h_{a3}, h_{v3} implicitly given by a single unknown: T_3

Trial and Error for T_3; $T_3 =$ **10°C**, $P_{g3} = 1.23$ kPa, $\phi_3 = \dfrac{P_{v3}}{P_{g3}} =$ **0.94**

If we solved with the psychrometric chart we would get:

State 1: $\dot{m}_{v1}/\dot{m}_a = \omega_1 = 0.002$, $\tilde{h}_1 = 65$ kJ/kg dry air;

State 3: $\omega_3 = (\dot{m}_{f2} / \dot{m}_{a1}) + \omega_1 = (0.00556/1.108) + 0.002 = 0.007$

Now the energy equation becomes

$$\tilde{h}_3 = \tilde{h}_1 + (\dot{m}_{f2}h_{f2} + \dot{Q})/\dot{m}_{a1} = 65 + (0.00556 \times 83.9 - 20)/1.108 = 47.4$$

Given ω_3 we find the state around **10°C** and $\phi_3 =$ **90%**

11.117

Compare the weather two places where it is cloudy and breezy. At beach A it is 20°C, 103.5 kPa, relative humidity 90% and beach B has 25°C, 99 kPa, relative humidity 40%. Suppose you just took a swim and came out of the water. Where would you feel more comfortable and why?

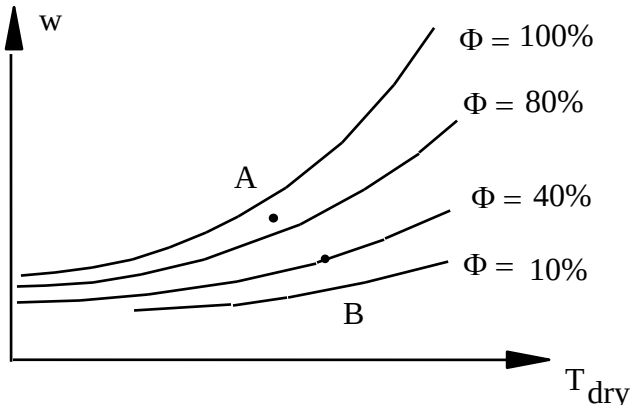
Solution:

As your skin is wet and air is flowing over it you will feel T_{wet}. With the small difference in pressure from 100 kPa we can use the psychrometric chart.

A: 20°C, ϕ = 90% => T_{wet} = 18.7°C

B: 25°C, ϕ = 40% => T_{wet} = 16°C

At beach A it is comfortable, at beach B it feels chilly.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.118

Ambient air at 100 kPa, 30°C, 40% relative humidity goes through a constant pressure heat exchanger as a steady flow. In one case it is heated to 45°C and in another case it is cooled until it reaches saturation. For both cases find the exit relative humidity and the amount of heat transfer per kilogram dry air.

Solution:

CV heat exchanger: $\dot{m}_{Ai} = \dot{m}_{Ae}$, $\dot{m}_{vi} = \dot{m}_{ve}$, $w_e = w_i$

$$(h_a + wh_v)_i + q = (h_a + wh_v)_e = \tilde{h}_e, \quad q = \tilde{h}_e - \tilde{h}_i$$

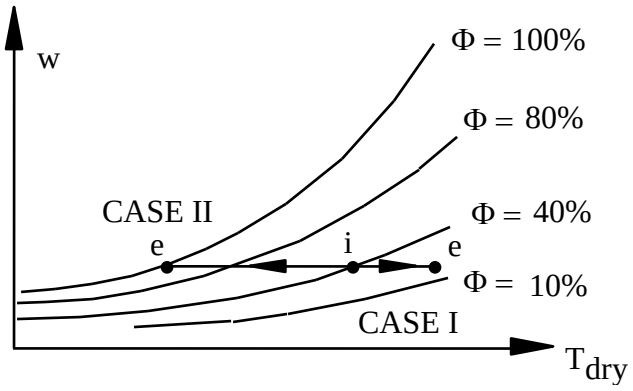
Using the psychrometric chart: i: $w_i = 0.0104$, $\tilde{h}_i = 76$

Case I) e: $T_e = 45\ ^oC$, $w_e = w_i$ => $\tilde{h}_e = 92$,

ϕ_e **= 17%,** $q = 92\text{-}76 =$ **16 kJ/kg dry air**

Case II) e: $w_e = w_i$, ϕ_e **= 100%** => $\tilde{h}_e = 61$, $T_e = 14.5^oC$

$q = 61\text{-}76 =$ **-15 kJ/kg dry air**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.119

A flow of moist air at 100 kPa, 35^{o}C, 40% relative humidity is cooled by adiabatic evaporation of liquid 20^{o}C water to reach a saturated state. Find the amount of water added per kg dry air and the exit temperature.

Since the liquid is not necessarily at the adiabatic saturation temperature the exit may be close to but not exactly the wet bulb temperature. We will use that as a good guess and check the energy equation.

Chart E4: $T_{wet} = 23.6^{o}C$, $w_1 = 0.0138$, $\tilde{h}_{1\ mix} = 90$ kJ/kg

$w_2 = 0.0186$, $\tilde{h}_{2mix} = 90.6$ kJ/kg

Continuity Eq.: $\dot{m}_A(1 + w_1) + \dot{m}_{liq} = \dot{m}_A(1 + w_2)$

Energy Eq. (q = 0): $\dot{m}_A\tilde{h}_{1mix} + \dot{m}_{liq}h_f = \dot{m}_A\tilde{h}_{2mix}$

Divide the energy equation by the mass flow rate of air

$\dot{m}_{liq}/\dot{m}_A = w_2 - w_1 = 0.0186 - 0.0138 = 0.0048$ kg water/kg air

so

$$\tilde{h}_{1mix} + (w_2 - w_1)\, h_f = \tilde{h}_{2mix}$$

LHS = 90 + 0.0048 × 83.94 = 90.4; RHS = 90.6

The temperature should be a little lower which will lower w_2 also so

$T_2 = \mathbf{23.5^{o}C}$, $w_2 = 0.0185$ => $\dot{m}_{liq}/\dot{m}_A = \mathbf{0.0047}$ **kg water/kg air**

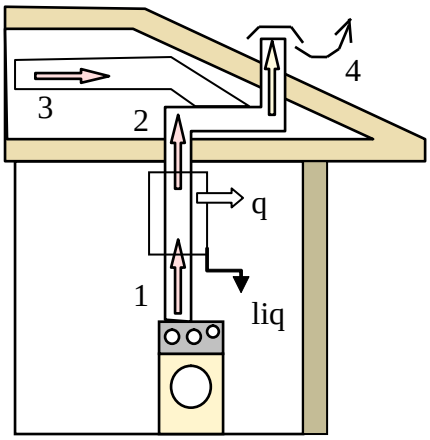
This is close to the accuracy by which we can read the chart and the first answer is nearly as good.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.120

A flow out of a clothes dryer of 0.1 kg/s dry air is at 60°C and relative humidity 60%. It flows through a heat exchanger where it exits at 20°C. After the heat exchanger the flow combines with another flow of 0.03 kg/s dry air at 30°C and relative humidity 40%. Find the dew point of state 1, see Fig. P11.120, the heat transfer per kg dry air and the final exit state humidity ratio and relative humidity.

Use the psychrometric chart to solve the problem except for state 1.



State 1: $P_{g1} = 19.941$ kPa,

$P_{v1} = \Phi_1 P_{g1} = 11.965$ kPa

$T_{dew} = T_{sat}(P_{v1}) =$ **49.3°C**

$$\omega_1 = 0.622 \frac{11.965}{100 - 11.965} = 0.084534$$

$\tilde{h}_1 = h_{a1} - h_{a\,-20C} + \omega_1 h_{a1}$

$= 333.81 - 253.45 + 0.084534 \times 2609.59$

$= 301$ kJ/kg air,

State 2: $20°C < T_{dew}$ so it is saturated

$\omega_2 = 0.0148$, $\tilde{h}_2 = 77.8$ kJ/kg air

State 3: $\omega_3 = 0.0078$, $\tilde{h}_3 = 69.8$ kJ/kg air,

$$\dot{m}_{liq}/\dot{m}_a = \omega_1 - \omega_2 = 0.06973 \text{ kg/kg dry air}$$

Energy Eq.: $\dot{Q}/\dot{m}_a = \tilde{h}_1 - \tilde{h}_2 - (\omega_1 - \omega_2) h_f$

$= 301 - 77.8 - 0.06973 \times 83.94 =$ **217.35 kJ/kg dry air**

Do CV around the junction where flow 2 and 3 combines to give exit at 4.

Continuity water: $\dot{m}_{a1}\,\omega_2 + \dot{m}_{a3}\,\omega_3 = \dot{m}_{a4}\,\omega_4$

$$\omega_4 = (\dot{m}_{a1}/\dot{m}_{a4})\,\omega_2 + (\dot{m}_{a3}/\dot{m}_{a4})\,\omega_3$$

$$= \frac{0.05}{0.08} \times 0.0148 + \frac{0.03}{0.08} \times 0.0078 = \mathbf{0.012175}$$

Energy Equation: $\dot{m}_{a1}\,\tilde{h}_2 + \dot{m}_{a3}\,\tilde{h}_3 = \dot{m}_{a4}\,\tilde{h}_4$

$$\tilde{h}_4 = (\dot{m}_{a1}/\dot{m}_{a4})\,\tilde{h}_2 + (\dot{m}_{a3}/\dot{m}_{a4})\,\tilde{h}_3$$

$$= \frac{0.05}{0.08} \times 77.8 + \frac{0.03}{0.08} \times 69.8 = 74.8 \text{ kJ/kg air}$$

From chart given $(\omega_4, \tilde{h}_4)$ we get: $\Phi_4 =$ **65%** and $T_4 = 24°C$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.121

Consider two states of atmospheric air. (1) 40°C, ϕ = 50% and (2) 25°C, T_{wet} = 16°C. Suggest a system of devices that will allow air in a steady flow process to change from (1) to (2) and from (2) to (1). Heaters, coolers (de)humidifiers, liquid traps etc. are available and any liquid/solid flowing is assumed to be at the lowest temperature seen in the process. Find the specific and relative humidity for state 1, dew point for state 2 and the heat transfer per kilogram dry air in each component in the systems.

Use the psychrometric chart E.4

1: $w_1 = 0.0232$, $\tilde{h}_1 = 118.5$, $\Phi_1 = 50\%$, $T_{dew} = 27.2°C$, $\tilde{h}_{dew} = 106$

2: $w_2 = 0.0077$, $\tilde{h}_2 = 65$, $\Phi_2 = 40\%$, $T_{dew} = 10.2°C$, $\tilde{h}_{dew} = 50$

Since $w_2 < w_1$ water must be removed in process I to II and added in the process II to I. Water can only be removed by cooling below dew point temperature so

I to II: Cool to dew point, 3, then cool to state 4 (dew pt. for state 2) while liquid water is removed, then heat to state 2.

II to I: Heat while adding water, once w_2 reached only heat.

$$\dot{m}_{liq}/\dot{m}_a = \omega_1 - \omega_2 = 0.0232 - 0.0077 = 0.0155$$

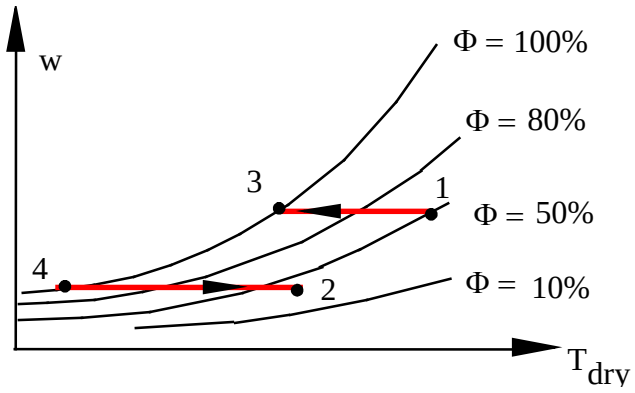
I to II: $q_{cool} = \tilde{h}_1 - \tilde{h}_4 - (\omega_1 - \omega_2)\, h_{f4}$

$= 118.5 - 50 - 0.0155 \times 42.83 =$ **67.8 kJ/kg air**

$q_{heat} = \tilde{h}_2 - \tilde{h}_4 = 65 - 50 =$ **15 kJ/kg air**

II to I: $q_{heat} = \tilde{h}_1 - \tilde{h}_2 - (\omega_1 - \omega_2)\, h_{f2}$

$= 118.5 - 65 - 0.0155 \times 104.87 =$ **51.9 kJ/kg air**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.122

To refresh air in a room, a counterflow heat exchanger, see Fig. P11.122, is mounted in the wall, drawing in outside air at 0.5°C, 80% relative humidity and pushing out room air, 40°C, 50% relative humidity. Assume an exchange of 3 kg/min dry air in a steady flow device, and also that the room air exits the heat exchanger at 23°C to the outside. Find the net amount of water removed from the room, any liquid flow in the heat exchanger and (T, ϕ) for the fresh air entering the room.

We will use the psychrometric chart to solve this problem.

State 3 (room): $w_3 = 0.0232$, $\tilde{h}_3 = 119.2$, $T_{dew\,3} = 27°C$

State 1(outside): 0.5°C, $\phi = 80\%$ => $w_1 = 0.0032$, $\tilde{h}_1 = 29.2$ kJ/kg dry air

CV room: $\dot{m}_{v,out} = \dot{m}_a (w_3 - w_2) = \dot{m}_a (w_3 - w_1)$

$= 3(0.0232-0.0032) =$ **0.06 kg/min**

The room air is cooled to 23°C $< T_{dew\,3}$ so liquid will form in the exit flow channel and state 4 is saturated.

State 4: 23°C, $\phi = 100\%$ => $w_4 = 0.0178$, $\tilde{h}_4 = 88$, $h_{f4} = 96.52$ kJ/kg

CV 3 to 4 (flow cooled below $T_{dew\,3}$ so liquid forms):

$$\dot{m}_{liq\,4} = \dot{m}_a (w_3 - w_4) = 3\,(0.0232 - 0.0178) = \textbf{0.0162 kg/min}$$

CV Heat exchanger with no external heat transfer:

$$m_a(\tilde{h}_2 - \tilde{h}_1) = m_a(\tilde{h}_3 - \tilde{h}_4) - m_{liq}h_{f4}$$

$\tilde{h}_2 = \tilde{h}_1 + \tilde{h}_3 - \tilde{h}_4 - (w_3-w_4)\, h_{f4} = 29.2 + 119.2 - 88 - 0.0054\times96.52$

$= 59.9$ kJ/kg dry air

State 2: $w_2 = w_1$, $\tilde{h}_2$ => $T_2 =$ **32.5°C**, $\phi =$ **12%**

Exergy in mixtures

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.123

Consider several flow processes with ideal gasses: 1) A compression of a gas mixture from 100 kPa to 200 kPa; 2) Cooling a gas mixture from 50°C to ambient 20°C using ambient air; 3) Mixing two different gasses at 100 kPa; 4) Throttle a gas mixture from 125 kPa to 100 kPa. For each case explain: What happens to the exergy, is there any exergy destruction and is the composition needed?

1. Exergy increases, mixture specific heat and gas constant needed.
2. Exergy decreases of mixture and some exergy is destroyed due to heat transfer over ΔT. Specific heat for mixture needed.
3. Composition needed, exergy is destroyed.
4. Exergy is destroyed, mixture gas constant needed

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.124

Find the second law efficiency of the heat exchanger in Problem 11.54.
A flow of 2 kg/s mixture of 50% CO_2 and 50% O_2 by mass is heated in a constant pressure heat exchanger from 400 K to 1000 K by a radiation source at 1400 K. Find the rate of heat transfer and the entropy generation in the process.

Solution:

The second law efficiency follows Eq.11.32 where the wanted term is the flow increase of exergy and the source is the radiation.

$$\dot{\Phi}_{flow} = \dot{m}(\psi_{ex} - \psi_{in}); \qquad \dot{\Phi}_{source} = \dot{Q}_{in}\,(1 - \frac{T_o}{T_{source}})$$

Heat exchanger Energy Eq.4.12: $\dot{Q}_{in} = \dot{m}(h_e - h_i)$

Values from Table A.8 due to the high T.

$$\dot{Q}_{in} = 2\,[\frac{1}{2} \times (971.67 - 303.76) + \frac{1}{2} \times (980.95 - 366.03)] = 1282.8 \text{ kW}$$

$$\dot{\Phi}_{source} = \dot{Q}_{in}\,(1 - \frac{T_o}{T_{source}}) = 1282.8\,(\,1 - \frac{298.15}{1400}) = 1009.6 \text{ kW}$$

Entropy Eq.7.8: $\dot{m}_e s_e = \dot{m}_i s_i + \dot{Q}/T_s + \dot{S}_{gen}$

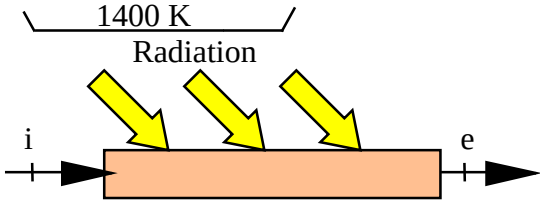
As P = C, the pressure correction in Eq.6.28 drops out to give generation as

$$\dot{S}_{gen} = \dot{m}(s_e - s_i) - \dot{Q}/T_s$$
$$= 2\,[0.5 \times (6.119 - 5.1196) + 0.5 \times (7.6121 - 6.6838)] - 1282.8/1400$$
$$= 1.01 \text{ kW/K}$$

$$\dot{\Phi}_{flow} = \dot{\Phi}_{source} - \dot{\Phi}_{destruction} = \dot{\Phi}_{source} - T\,\dot{S}_{gen}$$
$$= 1009.6 - 298.15 \times 1.01 = 708.5$$

$$\eta = \frac{\dot{\Phi}_{flow}}{\dot{\Phi}_{source}} = \frac{708.5}{1009.6} = \mathbf{0.70}$$

Remark: We could also explicitly have found the flow exergy increase.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.125

Consider the mixing of a steam flow with an oxygen flow in Problem 11.55. Find the rate of total inflowing exergy and the rate of exergy destruction in the process.

A flow of 1.8 kg/s steam at 400 kPa, 400°C is mixed with 3.2 kg/s oxygen at 400 kPa, 400 K in a steady flow mixing-chamber without any heat transfer. Find the exit temperature and the rate of entropy generation.

Exergy Flow: $\dot{\Phi}_{in} = \dot{m}\, \psi_{in} = \dot{m}_{H2O}\, \psi_1 + \dot{m}_{O2}\, \psi_2$

$$\psi_1 = h_1 - h_o - T_o(s_1 - s_o)$$

$$= C_{P\,H2O}(T_1 - T_o) - T_o\,[C_{P\,H2O} \ln(T_1/T_o) - R \ln(P_1/P_o)]$$

$$= 1.872\,(400 - 25) - 298.15[\,1.872 \ln \frac{673.15}{298.15} - 0.4615 \ln \frac{400}{100}\,]$$

$$= 702 - 298.15\,(1.5245 - 0.63978) = 438.2 \text{ kJ/kg}$$

$$\psi_2 = h_2 - h_o - T_o(s_2 - s_o)$$

$$= C_{P\,O2}(T_2 - T_o) - T_o\,[C_{P\,O2} \ln(T_2/T_o) - R \ln(P_2/P_o)]$$

$$= 0.922(126.85 - 25) - 298.15[0.922 \ln \frac{400}{298.15} - 0.2598 \ln \frac{400}{100}\,]$$

$$= 93.906 - 298.15\,(0.27095 - 0.36016) = 120.5 \text{ kJ/kg}$$

$$\dot{\Phi}_{in} = \dot{m}_{H2O}\, \psi_1 + \dot{m}_{O2}\, \psi_2 = 1.8\ 438.2 + 3.2\ 120.5 = \mathbf{1174.4\ kW}$$

C.V. Mixing chamber, steady flow, no work, no heat transfer. To do the entropies we need the mole fractions.

$$\dot{n}_{H2O} = \frac{\dot{m}_{H2O}}{M_{H2O}} = \frac{1.8}{18.015} = 0.1 \text{ kmol/s}; \quad \dot{n}_{O2} = \frac{\dot{m}_{O2}}{M_{O2}} = \frac{3.2}{31.999} = 0.1 \text{ kmol/s}$$

$$y_{H2O} = y_{O2} = 0.5$$

Energy Eq.: $\dot{m}_{H2O}\, h_1 + \dot{m}_{O2}\, h_2 = \dot{m}_{H2O}\, h_{3\,H2O} + \dot{m}_{O2}\, h_{3\,O2}$

Entropy Eq.: $\dot{m}_{H2O}\, s_1 + \dot{m}_{O2}\, s_2 + \dot{S}_{gen} = \dot{m}_{H2O}\, s_{3\,H2O} + \dot{m}_{O2}\, s_{3\,O2}$

Solve for T from the energy equation

$$\dot{m}_{H2O}\,(h_{3\,H2O} - h_1) + \dot{m}_{O2}\,(h_{3\,O2} - h_2) = 0$$

$$\dot{m}_{H2O}\, C_{P\,H2O}(T_3 - T_1) + \dot{m}_{O2}\, C_{P\,O2}(T_3 - T_2) = 0$$

$$1.8 \times 1.872\,(T_3 - 400 - 273.15) + 3.2 \times 0.922(T_3 - 400) = 0$$

$$T_3 = \mathbf{545.6\ K}$$

$$\dot{S}_{gen} = \dot{m}_{H2O}\,(s_{3\,H2O} - s_1) + \dot{m}_{O2}\,(s_{3\,O2} - s_2)$$

$$= \dot{m}_{H2O}\,[\,C_{P\,H2O} \ln \frac{T_3}{T_1} - R \ln y_{H2O}\,] + \dot{m}_{O2}\,[\,C_{P\,O2} \ln \frac{T_3}{T_2} - R \ln y_{O2}\,]$$

$$= 1.8\,[\,1.872 \ln \frac{545.6}{673.15} - 0.4615 \ln 0.5\,]$$

$$+ 3.2\,[\,0.922 \ln \frac{545.6}{400} - 0.2598 \ln 0.5\,]$$

$$= -0.132 + 1.492 = \mathbf{1.36\ kW/K}$$

The exergy destruction is proportional to the entropy generation

$$\dot{\Phi}_{in} = T_o\,\dot{S}_{gen} = 298.15 \times 1.36 = \mathbf{405.5\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.126

A mixture of 75% carbon dioxide and 25% water by mole is flowing at 1600 K, 100 kPa into a heat exchanger where it is used to deliver energy to a heat engine. The mixture leave the heat exchanger at 500 K with a mass flow rate of 2 kg/min. Find the rate of energy and the rate of exergy delivered to the heat engine.

C.V. Heat exchanger, steady flow and no work.

From Table A.8:

CO2: $h_{in} = 1748.12$ kJ/kg, $s^o_{T\,in} = 6.7254$ kJ/kg K

CO2: $h_{ex} = 401.52$ kJ/kg, $s^o_{T\,ex} = 5.3375$ kJ/kg K

H2O: $h_{in} = 3487.69$ kJ/kg, $s^o_{T\,in} = 14.0822$ kJ/kg K

H2O: $h_{ex} = 935.12$ kJ/kg, $s^o_{T\,ex} = 11.4644$ kJ/kg K

Energy Eq.: $\dot{Q} = \dot{m}\,(h_{in} - h_{ex}) = \dot{m} \sum c_i\,(h_{in} - h_{ex})_i$

$$= \frac{2}{60}\,[0.75\,(1748.12 - 401.52) + 0.25(3487.69 - 935.12)]$$

$$= \frac{1}{30}\,[\,1009.95 + 638.14\,] = \mathbf{54.94\ kW}$$

Entropy change (P does not change so partial pressures are constant):

$$s_{in} - s_{ex} = 0.75(6.7254 - 5.3375) + 0.25(14.0822 - 11.9644)$$
$$= 1.6954 \text{ kJ/kg K}$$

Exergy Flux:

$$\dot{\Phi} = \dot{m}\,(\psi_{in} - \psi_{ex}) = \dot{Q} - T_o\,\dot{m}\,(s_{in} - s_{ex})$$

$$= 54.94 - 298.15 \times \frac{1}{30} \times 1.6954$$

$$= \mathbf{38.09\ kW}$$

11.127

For flows with moist air where the water content is changed either by evaporation or by condensation what happens to the exergy? Is the water vapor in air flowing over a lake in equilibrium with the liquid water?

If the liquid water and the water vapor in the air were in thermodynamic equilibrium then there would be no tendency to move from one phase to the other. The water vapor is at its partial pressure and the air mixture temperature whereas the liquid water is at 1 atm pressure and at the liquid water temperature. In such situations equilibrium is attained when the partial Gibbs function ($g = h - Ts$) of the water is the same in the two phases, see Chapter 14. Notice if $T = T_o$ the Gibbs function becomes the same expression as for the flow exergy. The water will transport from the higher Gibbs function (exergy) towards the lower Gibbs function (exergy) if there is a difference between the two.

The difference then determines if evaporation or condensation occurs. If the temperature of the liquid and vapor is the same then the vapor should be at the saturated pressure P_g (plus a very small amount ε) to be in equilibrium with the liquid. When the conditions are close to equilibrium the exergy of the water in the two phases are nearly equal and there is then no difference in the exergy.

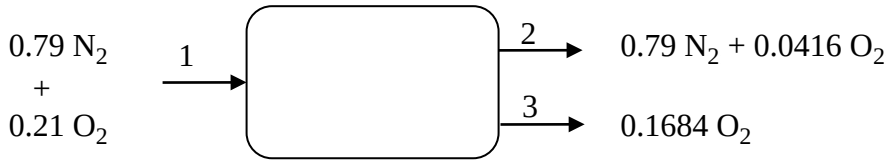
11.128

A semi-permeable membrane is used for the partial removal of oxygen from air that is blown through a grain elevator storage facility. Ambient air (79% nitrogen, 21% oxygen on a mole basis) is compressed to an appropriate pressure, cooled to ambient temperature 25°C, and then fed through a bundle of hollow polymer fibers that selectively absorb oxygen, so the mixture leaving at 120 kPa, 25°C, contains only 5% oxygen. The absorbed oxygen is bled off through the fiber walls at 40 kPa, 25°C, to a vacuum pump. Assume the process to be reversible and adiabatic and determine the minimum inlet air pressure to the fiber bundle.

State 1 is the air inlet, state 2 is the 5% [= 0.0416/(0.79 + 0.0416)] oxygen exit mix, state 3 pure O_2 exit.



Let reference be at state 1 so $s = 0$ at $T = 25^oC$ & P_1

$$\bar{s}_{MIX\,1} = 0 + 0 - y_{A1}\bar{R} \ln y_{A1} - y_{B1}\bar{R} \ln y_{B1}$$

$$\bar{s}_{MIX\,2} = 0 + 0 - \bar{R} \ln (P_2/P_1) - y_{A2}\bar{R} \ln y_{A2} - y_{B2}\bar{R} \ln y_{B2}$$

Pure O_2: $\bar{s}_3 = 0 - \bar{R} \ln (P_3/P_1)$

Entropy equation: $\dot{n}_1\bar{s}_1 = \dot{n}_2\bar{s}_2 + \dot{n}_3\bar{s}_3$

All T's the same, so only partial pressure terms

$$\bar{R}\Big[-0.8316 \ln (P_2/P_1) - 0.79 \ln 0.95 - 0.0416 \ln 0.05$$

$$- 0.1684 \ln (P_3/P_1) + 0.79 \ln 0.79 + 0.21 \ln 0.21\Big] = 0$$

$$0.8316 \ln (P_2/P_1) + 0.1684 \ln (P_3/P_1) = -0.3488 + 4.6025 - \ln P_1 = -0.3488$$

$P_{1\,min}$ = **141 kPa**

For $P_1 > P_{1\,min}$ we would have entropy generation $\Delta\dot{S} > 0$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.129

Weighing of masses gives a mixture at 60°C, 225 kPa with 0.5 kg O_2, 1.5 kg N_2 and 0.5 kg CH_4. Find the partial pressures of each component, the mixture specific volume (mass basis), mixture molecular weight and the total volume.

Solution:

From Eq.11.4: $y_i = (m_i / M_i) / \sum m_j/M_j$

$n_{tot} = \sum m_j/M_j = (0.5/31.999) + (1.5/28.013) + (0.5/16.04)$

$= 0.015625 + 0.053546 + 0.031172 = 0.100343$

$y_{O2} = 0.015625/0.100343 = 0.1557,$

$y_{N2} = 0.053546/0.100343 = 0.5336,$

$y_{CH4} = 0.031172/0.100343 = 0.3107$

From Eq.11.10:

$P_{O2} = y_{O2} P_{tot} = 0.1557 \times 225 = 35$ kPa,

$P_{N2} = y_{N2} P_{tot} = 0.5336 \times 225 = 120$ kPa

$P_{CH4} = y_{CH4} P_{tot} = 0.3107 \times 225 = 70$ kPa

$V_{tot} = n_{tot} \bar{R}T/P = 0.100343 \times 8.31451 \times 333.15 / 225 =$ **1.235 m^3**

$v = V_{tot}/m_{tot} = 1.235 / (0.5 + 1.5 + 0.5) =$ **0.494 m^3/kg**

From Eq.11.5:

$M_{mix} = \sum y_j M_j = m_{tot}/n_{tot} = 2.5/0.100343 =$ **24.914**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.130

A carbureted internal combustion engine is converted to run on methane gas (natural gas). The air-fuel ratio in the cylinder is to be 20 to 1 on a mass basis. How many moles of oxygen per mole of methane are there in the cylinder?

Solution:

The mass ratio $m_{AIR}/m_{CH_4} = 20$, so relate mass and mole $n = m/M$

$$\frac{n_{AIR}}{n_{CH_4}} = \left(\frac{m_{AIR}}{m_{CH_4}}\right) \times M_{CH_4}/M_{AIR} = 20 \times 16.04/28.97 = 11.0735$$

$$\rightarrow \frac{n_{O_2}}{n_{CH_4}} = \frac{n_{O_2}}{n_{AIR}} \times \frac{n_{AIR}}{n_{CH_4}} = 0.21 \times 11.0735 = \mathbf{2.325\ mole\ O_2/mole\ CH_4}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.131

A mixture of 50% carbon dioxide and 50% water by mass is brought from 1500 K, 1 MPa to 500 K, 200 kPa in a polytropic process through a steady state device. Find the necessary heat transfer and work involved using values from Table A.5.

Solution:

Process Pv^n = constant leading to

$$n \ln(v_2/v_1) = \ln(P_1/P_2); \quad v = RT/P$$

$$n = \ln\left(\frac{1000}{200}\right) / \ln\left(\frac{500 \times 1000}{200 \times 1500}\right) = 3.1507$$

Eq.11.15: $R_{mix} = \Sigma\, c_i R_i = 0.5 \times 0.1889 + 0.5 \times 0.4615 = 0.3252$ kJ/kg K

Eq.11.23: $C_{P\,mix} = \Sigma\, c_i C_{Pi} = 0.5 \times 0.8418 + 0.5 \times 1.872 = 1.3569$ kJ/kg K

Work is from Eq.7.18:

$$w = -\int v dP = -\frac{n}{n-1}(P_e v_e - P_i v_i) = -\frac{nR}{n-1}(T_e - T_i) = \mathbf{476.4\ kJ/kg}$$

Heat transfer from the energy equation

$$q = h_e - h_i + w = C_P(T_e - T_i) + w = \mathbf{-880.5\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.132

The accuracy of calculations can be improved by using a better estimate for the specific heat. Reconsider the previous problem and use $C_P = \Delta h/\Delta T$, from Table A.8 centered at 1000 K.

A mixture of 50% carbon dioxide and 50% water by mass is brought from 1500 K, 1 MPa to 500 K, 200 kPa in a polytropic process through a steady state device. Find the necessary heat transfer and work involved using values from Table A.5.

Solution:

Using values from Table A.8 we estimate the heat capacities

$$C_{P\,CO_2} = \frac{1096.36 - 849.72}{1100 - 900} = 1.2332 \text{ kJ/kg K}$$

$$C_{P\,H_2O} = \frac{2226.73 - 1768.6}{1100 - 900} = 2.2906 \text{ kJ/kg K}$$

Eq.11.23: $C_{P\,mix} = \Sigma\, c_i C_{Pi} = 0.5 \times 1.2332 + 0.5 \times 2.2906 = 1.7619$ kJ/kg K

Eq.11.15: $R_{mix} = \Sigma\, c_i R_i = 0.5 \times 0.1889 + 0.5 \times 0.4615 = 0.3252$ kJ/kg K

Process $Pv^n = C$ => $n = \ln(P_1/P_2) / \ln(v_2/v_1)$ and use $Pv = RT$

$$n = \ln\left(\frac{1000}{200}\right) / \ln\left(\frac{500 \times 1000}{200 \times 1500}\right) = 3.1507$$

Work is from Eq.7.18

$$w = -\int v dP = -\frac{n}{n-1}(P_e v_e - P_i v_i) = -\frac{nR}{n-1}(T_e - T_i) = \mathbf{476.4\ kJ/kg}$$

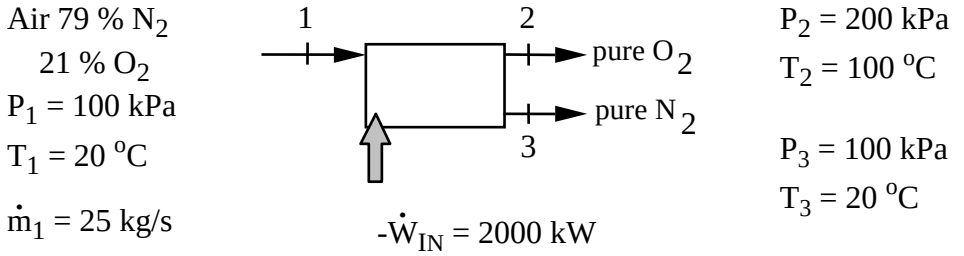
Heat transfer from energy equation

$$q = h_e - h_i + w = 1.7619(500 - 1500) + 476.4 = \mathbf{-1285.5\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.133

A large air separation plant takes in ambient air (79% N_2, 21% O_2 by mole) at 100 kPa, 20°C, at a rate of 25 kg/s. It discharges a stream of pure O_2 gas at 200 kPa, 100°C, and a stream of pure N_2 gas at 100 kPa, 20°C. The plant operates on an electrical power input of 2000 kW. Calculate the net rate of entropy change for the process.



Solution:

To have the flow terms on a mass basis let us find the mass fractions

From Eq. 11.3: $c_i = y_i M_i / \sum y_j M_j$

$c_{O_2} = 0.21 \times 32 / [0.21 \times 32 + 0.79 \times 28.013] = 0.23293$;

$c_{N_2} = 1 - c_{O_2} = 0.76707$

$\dot{m}_2 = c_{O_2}\dot{m}_1 = 5.823$ kg/s ; $\dot{m}_3 = c_{N_2}\dot{m}_1 = 19.177$ kg/s

The energy equation, Eq.4.10 gives the heat transfer rate as

$$\dot{Q}_{CV} = \Sigma \dot{m}\Delta h_i + \dot{W}_{CV} = \dot{m}_{O_2} C_{P0\,O_2}(T_2 - T_1) + \dot{m}_{N_2} C_{P0\,N_2}(T_3 - T_1) + \dot{W}_{CV}$$

$$= 5.823 \times 0.922 \times (100\text{-}20) + 0 - 2000 = -1570.5 \text{ kW}$$

The entropy equation, Eq.7.7 gives the generation rates as

$$\dot{S}_{gen} = \Sigma \dot{m}_i \Delta s_i - \dot{Q}_{CV}/T_0 = (\dot{m}_2 s_2 + \dot{m}_3 s_3 - \dot{m}_1 s_1) - \dot{Q}_{CV}/T_0$$

Use Eq.6.16 for the entropy change

$$\Sigma \dot{m}_i \Delta s_i = 5.823 \left[0.922 \ln \frac{373.2}{293.2} - 0.2598 \ln \frac{200}{21} \right]$$

$$+ 19.177 \, [0 - 0.2968 \ln (100/79)] = -3.456 \text{ kW/K}$$

$$\dot{S}_{gen} = 1570.5/293.2 - 3.456 = \mathbf{1.90\ kW/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.134

Take Problem 11.57 with inlet temperature of 1400 K for the carbon dioxide and 300 K for the nitrogen. First estimate the exit temperature with the specific heats from Table A.5 and use this to start iterations using A.9 to find the exit temperature.

CV mixing chamber, steady flow. The inlet ratio is $\dot{n}_{CO_2} = 2\,\dot{n}_{N_2}$ and assume no external heat transfer, no work involved.

$\bar{C}_{P\,CO_2} = 44.01 \times 0.842 = 37.06$; $\bar{C}_{P\,N_2} = 28.013 \times 1.042 = 29.189$ kJ/kmol K

Continuity Equation: $0 = \Sigma \dot{n}_{in} - \Sigma \dot{n}_{ex}$;

Energy Equation: $0 = \Sigma \dot{n}_{in}\, \bar{h}_{in} - \Sigma \dot{n}_{ex}\, \bar{h}_{ex}$

$$0 = 2\dot{n}_{N_2}\, \bar{C}_{P\,CO_2}(T_{in} - T_{ex})_{\,CO_2} + \dot{n}_{N_2}\, \bar{C}_{P\,N_2}\,(T_{in} - T_{ex})_{\,N_2}$$

$$0 = 2 \times 37.06 \times (1400 - T_{ex}) + 29.189 \times (300 - T_{ex})$$

$$0 = 103768 + 8756.7 - 103.309\, T_{ex} \quad \Rightarrow \quad \mathbf{T_{ex} = 1089\ K}$$

From Table A.9: $\Sigma \dot{n}_{in}\, \bar{h}_{in} = \dot{n}_{N_2}\,[2 \times 55895 + 1 \times 54] = \dot{n}_{N_2} \times 111844$

@ 1000K : $\Sigma \dot{n}_{ex}\, \bar{h}_{ex} = \dot{n}_{N_2}\,[2 \times 33397 + 21463] = \dot{n}_{N_2} \times 88257$

@ 1100K : $\Sigma \dot{n}_{ex}\, \bar{h}_{ex} = \dot{n}_{N_2}\,[2 \times 38885 + 24760] = \dot{n}_{N_2} \times 102530$

@ 1200K : $\Sigma \dot{n}_{ex}\, \bar{h}_{ex} = \dot{n}_{N_2}\,[2 \times 44473 + 28109] = \dot{n}_{N_2} \times 117055$

Now linear interpolation between 1100 K and 1200 K

$$T_{ex} = 1100 + 100 \times \frac{111844 - 102530}{117055 - 102530} = \mathbf{1164\ K}$$

11.135

A piston/cylinder has 100 kg of saturated moist air at 100 kPa, 5°C. If it is heated to 45°C in an isobaric process, find $_1Q_2$ and the final relative humidity. If it is compressed from the initial state to 200 kPa in an isothermal process, find the mass of water condensing.

Solution:

Energy Eq.: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$,

Initial state 1: $\phi_1 = 100\%$, Table B.1.1: $P_{v1} = 0.8721$ kPa, $h_{v1} = 2510.54$

Eq.11.28 $$w_1 = 0.622 \frac{P_{v1}}{P_{tot} - P_{v1}} = \frac{0.8721}{100 - 0.8721} = 0.005472$$

Eq.11.26 with $m_a = m_{tot} - m_{v1} = m_{tot} - w_1 m_a$ gives

$$m_a = m_{tot}/(1+ w_1) = 99.456 \text{ kg},$$

Eq.11.26 $$m_{v1} = w_1 m_a = 0.544 \text{ kg}$$

Case a: P = constant => $_1W_2 = mP(v_2-v_1)$ =>

$$_1Q_2 = m(u_2 - u_1) + {}_1W_2 = m(h_2 - h_1) = m_a C_p(T_2 - T_1) + m(h_{v2} - h_{v1})$$

State 2: $w_2 = w_1$, T_2 => $P_{v2} = P_{v1}$ and

Table B.1.1: $h_{v2} = 2583.19$ kJ/kg, $P_{g2} = 9.593$ kPa

Eq.11.25 $$\phi_2 = \frac{P_{v2}}{P_{g2}} = \frac{0.8721}{9.593} = 0.091 \quad \text{or} \quad \phi_2 = \mathbf{9.1\%}$$

From the energy equation

$$_1Q_2 = 99.456 \times 1.004(45 - 5) + 0.544(2583.19 - 2510.54) = \mathbf{4034\ kJ}$$

Case b: As P is raised $P_v = y_v P$ would be higher than P_g => condensation.

T = constant & $\phi_2 = 100\%$ => $P_v = P_g = 0.8721$ kPa

$$w_2 = 0.622 \frac{P_{v2}}{P_{a2}} = 0.622 \frac{P_{v2}}{P_{tot2} - P_{v2}} = \frac{0.8721}{200 - 0.8721} = 0.002724$$

$$m_{v2} = w_2 m_a = 0.271 \text{ kg}, \qquad m_{liq} = m_{v1} - m_{v2} = \mathbf{0.273\ kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.136

A piston/cylinder contains helium at 110 kPa at ambient temperature 20°C, and initial volume of 20 L as shown in Fig. P11.136. The stops are mounted to give a maximum volume of 25 L and the nitrogen line conditions are 300 kPa, 30°C. The valve is now opened which allows nitrogen to flow in and mix with the helium. The valve is closed when the pressure inside reaches 200 kPa, at which point the temperature inside is 40°C. Is this process consistent with the second law of thermodynamics?

$P_1 = 110$ kPa, $T_1 = 20\ ^oC$, $V_1 = 20$ L, $V_{max} = 25$ L $= V_2$

$P_2 = 200$ kPa, $T_2 = 40\ ^oC$, $P_i = 300$ kPa, $T_i = 30\ ^oC$

Constant P to stops, then constant V = V_{max} => $W_{cv} = P_1(V_2 - V_1)$

$$Q_{cv} = U_2 - U_1 + W_{cv} - n_i\bar{h}_i,$$

$$= n_2\bar{h}_2 - n_1\bar{h}_1 - n_i\bar{h}_i - (P_2 - P_1)V_2$$

$$= n_A(\bar{h}_{A2} - \bar{h}_{Ai}) + n_B(\bar{h}_{B2} - \bar{h}_{B1}) - (P_2 - P_1)V_2$$

$$n_B = n_1 = P_1V_1/\bar{R}T_1 = 110\times0.02/8.3145\times293.2 = 0.0009 \text{ kmol}$$

$$n_2 = n_A + n_B = P_2V_2/\bar{R}T_2 = 200\times0.025/8.3145\times313.2 = 0.00192 \text{ kmol},$$

$$n_A = n_2 - n_B = 0.00102 \text{ kmol}$$

Mole fractions: $y_{A2} = 0.00102/0.00192 = 0.5313$, $y_{B2} = 0.4687$

$$Q_{cv} = 0.00102\times28.013\times1.042(40 - 30) + 0.0009\times4.003\times5.193(40 - 20)$$
$$- (200 - 110)\ 0.025$$
$$= 0.298 + 0.374 - 2.25 = -1.578 \text{ kJ}$$

$$S_{gen} = n_2\bar{s}_2 - n_1\bar{s}_1 - n_i\bar{s}_i - Q_{cv}/T_0$$

$$= n_A(\bar{s}_{A2} - \bar{s}_{Ai}) + n_B(\bar{s}_{B2} - \bar{s}_{B1}) - Q_{cv}/T_0$$

$$\bar{s}_{A2} - \bar{s}_{Ai} = 29.189 \ln\frac{313.2}{303.2} - \bar{R}\ln\frac{0.5313*200}{300} = 9.5763$$

$$\bar{s}_{B2} - \bar{s}_{B1} = 20.7876 \ln\frac{313.2}{293.2} - \bar{R}\ln\frac{0.4687*200}{110} = 2.7015$$

$$S_{gen} = 0.00102\times9.5763 + 0.0009\times2.7015 + 1.578/293.2$$

$$= \mathbf{0.0176\ kJ/K > 0} \qquad \mathbf{Satisfies\ 2nd\ law.}$$

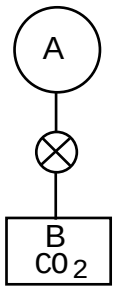
11.137

A spherical balloon has an initial diameter of 1 m and contains argon gas at 200 kPa, 40°C. The balloon is connected by a valve to a 500-L rigid tank containing carbon dioxide at 100 kPa, 100°C. The valve is opened, and eventually the balloon and tank reach a uniform state in which the pressure is 185 kPa. The balloon pressure is directly proportional to its diameter. Take the balloon and tank as a control volume, and calculate the final temperature and the heat transfer for the process.



$$V_{A1} = \frac{\pi}{6} 1^3 = 0.5236,$$

$$m_{A1} = \frac{P_{A1}V_{A1}}{RT_{A1}} = \frac{200 \times 0.5236}{0.208\ 13 \times 313.2} = 1.606 \text{ kg}$$

$$m_{B1} = P_{B1}V_{B1}/RT_{B1} = 100 \times 0.50/0.18892 \times 373.2 = 0.709 \text{ kg}$$

Process: $P = C\ D = CV^{1/3}$ ⇨ polytropic $n = -1/3$ ⇨

$$V_{A2} = V_{A1}\left(\frac{P_2}{P_{A1}}\right)^3 = 0.5236\left(\frac{185}{200}\right)^3 = 0.4144 \text{ m}^3$$

2: Uniform ideal gas mixture :

$$P_2(V_{A2} + V_B) = (m_A R_A + m_B R_B)T_2$$

$$T_2 = P_2(V_{A2} + V_B) / (m_A R_A + m_B R_B)$$

$$= 185\ (0.4144+0.50) / (1.606 \times 0.20813 + 0.709 \times 0.18892) = \mathbf{361.3\ K}$$

Boundary work in a polytropic process from Eq.6.29

$$W_{12} = \frac{P_2V_{A2} - P_{A1}V_{A1}}{1 - (-1/3)} = \frac{185 \times 0.4144 - 200 \times 0.5236}{(4/3)} \text{ kPa m}^3$$

$$= -21.0 \text{ kJ}$$

The heat transfer from the energy equation

$$Q = m_A C_{V0A}(T_2 - T_{A1}) + m_B C_{V0B}(T_2 - T_{B1}) + W_{12}$$

$$= 1.606 \times 0.312(361.3 - 313.2) + 0.709 \times 0.653(361.3 - 373.2) - 21.0$$

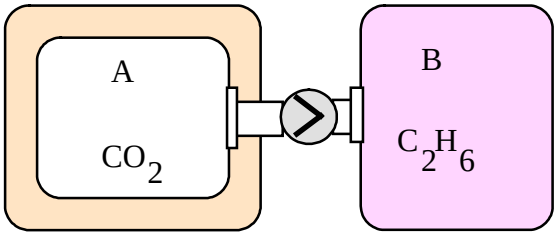
$$= 18.6 - 21.0 = \mathbf{-2.4\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.138

An insulated rigid 2 m^3 tank A contains CO_2 gas at 200°C, 1MPa. An uninsulated rigid 1 m^3 tank B contains ethane, C_2H_6, gas at 200 kPa, room temperature 20°C. The two are connected by a one-way check valve that will allow gas from A to B, but not from B to A. The valve is opened and gas flows from A to B until the pressure in B reaches 500 kPa and the valve is closed. The mixture in B is kept at room temperature due to heat transfer. Find the total number of moles and the ethane mole fraction at the final state in B. Find the final temperature and pressure in tank A and the heat transfer to/from tank B.

Solution:



Tank A: $V_A = 2\ m^3$, state A_1 : CO_2, $T_{A1} = 200°C = 473.2\ K$, $P_{A1} = 1\ MPa$

$\bar{C}_{v0\ CO_2} = 0.653 \times 44.01 = 28.74$, $\bar{C}_{P0\ CO_2} = 0.842 \times 44.01 = 37.06$ kJ/kmol K

Tank B: $V_B = 1\ m^3$, state B_1: C_2H_6, $T_{B1} = 20°C = 293.2\ K$, $P_{B1} = 200$ kPa

Slow Flow A to B to $P_{B2} = 500$ kPa and assume $T_{B2} = T_{B1} = T_0$

Total moles scales to pressure, so with same V and T we have

$$P_{B1}V_B = n_{B1}\bar{R}T_{B1}\ , \qquad P_{B2}V_B = n_{B2\ mix}\,\bar{R}T_{B2}$$

Mole fraction: $$y_{C_2H_6\ B_2} = \frac{n_{B1}}{n_{B2}} = \frac{P_{B1}}{P_{B2}} = \frac{200}{500} = \mathbf{0.400}$$

$$n_{B1} = \frac{P_{B1}V_B}{RT_{B1}} = \frac{200 \times 1}{R \times 293.2} = 0.08204\ \text{kmol}$$

$$n_{B2\ mix} = \frac{P_{B2}V_B}{RT_{B2}} = \frac{500 \times 1}{R \times 293.2} = 0.2051\ \text{kmol}$$

$$n_{CO_2\ B2} = 0.2051 - 0.08201 = 0.12306\ \text{kmol}$$

Now we can work backwards to final state in A

$$n_{A1} = \frac{P_{A1}V_A}{RT_{A1}} = \frac{1000 \times 2}{R \times 473.2} = 0.50833\ \text{kmol};\ \ n_{A2} = n_{A1} - n_{CO_2\ B2} = 0.38527\ \text{kmol}$$

11.139

You have just washed your hair and now blow dry it in a room with 23°C, ϕ = 60%, (1). The dryer, 500 W, heats the air to 49°C, (2), blows it through your hair where the air becomes saturated (3), and then flows on to hit a window where it cools to 15°C (4). Find the relative humidity at state 2, the heat transfer per kilogram of dry air in the dryer, the air flow rate, and the amount of water condensed on the window, if any.

The blowdryer heats the air at constant specific humidity to 2 and it then goes through an adiabatic saturation process to state 3, finally cooling to 4.

1: 23°C, 60% rel hum => $w_1 = 0.0104$, $\tilde{h}_1 = 69$ kJ/kg dry air

2: $w_2 = w_1$, T_2 => ϕ_2 **= 15%**, $\tilde{h}_2 = 95$ kJ/kg dry air

CV. 1 to 2: $w_2 = w_1$; $q = \tilde{h}_2 - \tilde{h}_1 = 95 - 69 =$ **26 kJ/kg dry air**

$$\dot{m}_a = Q/q = 0.5/26 = \textbf{0.01923 kg/s}$$

CV. 2 to 3: $w_3 - w_2 = \dot{m}_{liq}/\dot{m}_a$; $\dot{m}_a \tilde{h}_2 + \dot{m}_{liq} h_f = \dot{m}_a \tilde{h}_3$

3: $\phi = 100\%$ => $T_3 = \mathbf{T_{wet,2} = 24.8°C}$, $w_3 =$ **0.0198**

4: $\phi = 100\%$, T_4 => $w_4 = 0.01065$

$\dot{m}_{liq} = (w_3 - w_4)\, \dot{m}_a = (0.0198 - 0.01065) \times 0.01923 =$ **0.176 g/s**

If the steam **tables and formula's** are used then we get

$h_{g1} = 2543.5$, $h_{g2} = 2590.3$, $P_{g1} = 2.837$ kPa, $P_{v1} = 1.7022$ kPa,

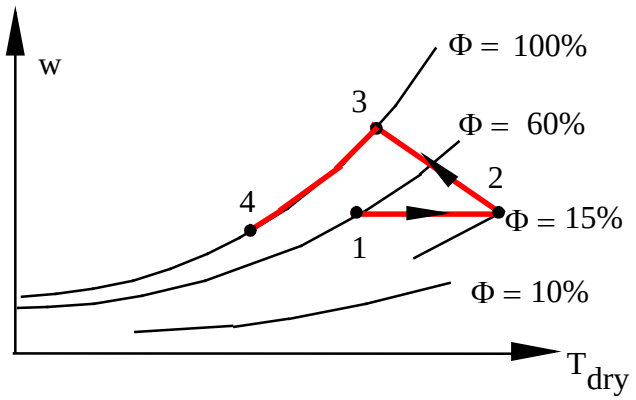
$P_{g2} = 11.8$ kPa, $w_1 = 0.01077$, $w_2 = w_1$, $P_{v2} = P_{v1}$

$\phi_2 = P_{v2}/P_{g2} = 14.4\%$, $h_{f3} = 114$ kJ/kg,

Trial and error for adiabatic saturation temperature.

$T_3 = 25$°C, $w_3 = 0.02$, $P_{v4} = P_{g4} = 1.705$ kPa,

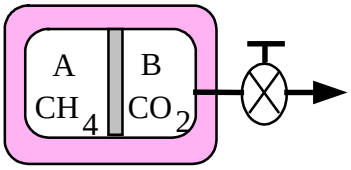
$w_4 = 0.622 \times 1.705/(100-1.705) = 0.0108$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.140

A 0.2 m^3 insulated, rigid vessel is divided into two equal parts A and B by an insulated partition, as shown in Fig. P11.140. The partition will support a pressure difference of 400 kPa before breaking. Side A contains methane and side B contains carbon dioxide. Both sides are initially at 1 MPa, 30°C. A valve on side B is opened, and carbon dioxide flows out. The carbon dioxide that remains in B is assumed to undergo a reversible adiabatic expansion while there is flow out. Eventually the partition breaks, and the valve is closed. Calculate the net entropy change for the process that begins when the valve is closed.



ΔP_{MAX} = 400 kPa, $P_{A1} = P_{B1}$ = 1 MPa

$V_{A1} = V_{B1}$ = 0.1 m^3

$T_{A1} = T_{B1}$ = 30°C = 303.2 K

CO_2 inside B: $s_{B2} = s_{B1}$ to P_{B2} = 600 kPa (P_{A2} = 1000 kPa)

For CO_2, k = 1.289 => $T_{B2} = 303.2\left(\frac{600}{1000}\right)^{\frac{0.289}{1.289}} = 270.4$ K

$n_{B2} = P_{B2}V_{B2}/\bar{R}T_{B2} = 600\times0.1/8.3145\times270.4 = 0.026\,688$

$n_{A2} = n_{A1} = 1000\times0.1/8.3145\times303.2 = 0.039\,668$ kmol

The process 2 to 3 is adiabatic but irreversible with no work.

$$Q_{23} = 0 = n_3\bar{u}_3 - \sum_i n_{i2}\bar{u}_{i2} + 0 = n_{A2}\bar{C}_{vo\,A}(T_3-T_{A2}) + n_{B2}\bar{C}_{vo\,B}(T_3-T_{B2}) = 0$$

$$0.039\,668\times16.04\times1.736(T_3-303.2) + 0.026\,688\times44.01\times0.653(T_3-270.4) = 0$$

Solve T_3 = 289.8 K

Get total and partial pressures for the entropy change

$P_3 = n\bar{R}T/V = 0.066356\times8.3145\times289.8/0.2 = 799.4$ kPa

$P_{A3} = 0.5978\times799.4 = 477.9$ kPa , $P_{B3} = P_3 - P_{A3} = 321.5$ kPa

$$\bar{s}_{A3} - \bar{s}_{A2} = 16.04\times2.254\ln\left(\frac{289.8}{303.2}\right) - 8.3145\ln\frac{477.9}{1000} = 4.505 \text{ kJ/kmol K}$$

$$\bar{s}_{B3} - \bar{s}_{B2} = 44.01\times0.842\ln\left(\frac{289.8}{270.4}\right) - 8.3145\ln\frac{321.5}{600} = 7.7546 \text{ kJ/kmol K}$$

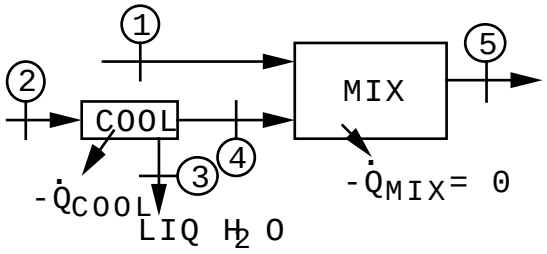
$\Delta S_{NET} = n_{A2}(\bar{s}_{A3} - \bar{s}_{A2}) + n_{B2}(\bar{s}_{B3} - \bar{s}_{B2})$

$= 0.039668 \times 4.505 + 0.026688 \times 7.7546 =$ **+0.3857 kJ/K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.141

Ambient air is at a condition of 100 kPa, 35°C, 50% relative humidity. A steady stream of air at 100 kPa, 23°C, 70% relative humidity, is to be produced by first cooling one stream to an appropriate temperature to condense out the proper amount of water and then mix this stream adiabatically with the second one at ambient conditions. What is the ratio of the two flow rates? To what temperature must the first stream be cooled?



$P_1 = P_2 = 100$ kPa

$T_1 = T_2 = 35\ ^oC$

$\phi_1 = \phi_2 = 0.50$, $\phi_4 = 1.0$

$P_5 = 100$, $T_5 = 23\ ^oC$

$\phi_5 = 0.70$

$P_{v1} = P_{v2} = 0.5 \times 5.628 = 2.814$ kPa => $w_1 = w_2 = 0.622 \times \dfrac{2.814}{100\text{-}2.814} = 0.0180$

$P_{v5} = 0.7 \times 2.837 = 1.9859$ kPa => $w_5 = 0.622 \times \dfrac{1.9859}{100\text{-}1.9859} = 0.0126$

C.V.: Mixing chamber: Call the mass flow ratio $r = m_{a2}/m_{a1}$

cons. mass: $w_1 + r\,w_4 = (1+r)w_5$

Energy Eq.: $h_{a1} + w_1 h_{v1} + r h_{a4} + r w_4 h_{v4} = (1+r)h_{a5} + (1+r)w_5 h_{v5}$

$\rightarrow 0.018 + r w_4 = (1+r)\ 0.0126$

or $r = \dfrac{m_{a2}}{m_{a1}} = \dfrac{0.018\text{-}0.0126}{0.0126\text{-}w_4}$, with $w_4 = 0.622 \times \dfrac{P_{G4}}{100\text{-}P_{G4}}$

$1.004 \times 308.2 + 0.018 \times 2565.3 + r \times 1.004 \times T_4 + r\,w_4 h_{v4}$

$= (1+r) \times 1.004 \times 296.2 + (1+r) \times 0.0126 \times 2543.6$

or $r\left[1.004 \times T_4 + w_4 h_{G4} - 329.3\right] + 26.2 = 0$

Assume $T_4 = \mathbf{5\ ^oC}$ $\rightarrow P_{G4} = 0.8721$, $h_{G4} = 2510.5$

$w_4 = 0.622 \times 0.8721/(100\text{-}0.8721) = 0.0055$

$r = m_{a2}/m_{a1} = \dfrac{0.018\text{-}0.0126}{0.0126\text{-}0.0055} = \mathbf{0.7606}$

$0.7606[1.004 \times 278.2 + 0.0055 \times 2510.5 - 329.6] + 26.2 = -1.42 \approx 0$ OK

11.142

An air-water vapor mixture enters a steady flow heater humidifier unit at state 1: 10°C, 10% relative humidity, at the rate of 1 m^3/s. A second air-vapor stream enters the unit at state 2: 20°C, 20% relative humidity, at the rate of 2 m^3/s. Liquid water enters at state 3: 10°C, at the rate of 400 kg per hour. A single air-vapor flow exits the unit at state 4: 40°C, as shown in Fig. P11.142. Calculate the relative humidity of the exit flow and the rate of heat transfer to the unit.

State 1: $T_1 = 10°C$, $\phi_1 = 10\%$, $\dot{V}_{a1} = 1\ m^3/s$

$P_{g1} = 1.2276$ kPa, $P_{v1} = \phi_1 P_{g1} = 0.1228$ kPa, $P_{a1} = P - P_{v1} = 99.877$ kPa

$$\omega_1 = 0.622 \frac{P_{v1}}{P_{a1}} = 0.000765, \quad \dot{m}_{a1} = \frac{P_{a1}\dot{V}_{a1}}{RT_{a1}} = 1.2288 \text{ kg/s}$$

$\dot{m}_{v1} = \omega_1 \dot{m}_{a1} = 0.00094$ kg/s, $h_{v1} = h_{g1} = 2519.7$ kJ/kg

State 2: $T_2 = 20°C$, $\phi_2 = 20\%$, $\dot{V}_{a2} = 2\ m^3/s$

$P_{g2} = 2.3385$ kPa, $P_{v2} = \phi\, P_{g2} = 0.4677$ kPa, $P_{a2} = P - P_{v2} = 99.532$ kPa

$$\omega_2 = 0.622 \frac{P_{v2}}{P_{a2}} = 0.002923, \quad \dot{m}_{a2} = \frac{P_{a2}\,\dot{V}_{a2}}{RT_{a2}} = 2.3656 \text{ kg/s}$$

$\dot{m}_{v2} = \omega_2 \dot{m}_{a2} = 0.00691$ kg/s, $h_{v2} = h_{g2} = 2538.1$ kJ/kg

State 3: Liquid. $T_3 = 10°C$, $\dot{m}_{f3} = 400$ kg/hr $= 0.1111$ kg/s, $h_{f3} = 42$ kJ/kg

Continuity Eq. air: $\dot{m}_{a4} = \dot{m}_{a2} + \dot{m}_{a1} = 3.5944$ kg/s,

Continuity Eq. water: $\dot{m}_{v4} = \dot{m}_{v1} + \dot{m}_{v2} + \dot{m}_{f3} = 0.11896$ kg/s

$$\omega_4 = \dot{m}_{v4}/\dot{m}_{a4} = 0.0331 = 0.622 \frac{P_{v4}}{P\text{-}P_{v4}} \quad \rightarrow \ P_{v4} = 5.052 \text{ kPa}$$

$P_{g4} = 7.384$ kPa, $\phi_4 = P_{v4}/P_{g4} =$ **0.684**, $h_{v4} = h_{g4} = 2574.3$ kJ/kg

Energy Eq.: $\dot{Q} + \dot{m}_{a1}h_{a1} + \dot{m}_{v1}h_{v1} + \dot{m}_{a2}h_{a2} + \dot{m}_{v2}h_{v2} + \dot{m}_{f3}h_{f3} = \dot{m}_{a4}h_{a4} + \dot{m}_{v4}h_{v4}$

$$\dot{Q} = 1.004(3.5944 \times 40 - 1.2288 \times 10 - 2.3656 \times 20) + 0.11896 \times 2574.3$$
$$- 0.00094 \times 2519.7 - 0.00691 \times 2538.1 - 0.1111 \times 42.0$$
$$= \mathbf{366\ kW}$$

11.143

A dehumidifier receives a flow of 0.25 kg/s dry air at 35°C, 90% relative humidity as shown in figure P11.107. It is cooled down to 20°C as it flows over the evaporator and then heated up again as it flows over the condenser. The standard refrigeration cycle uses R-410A with an evaporator temperature of –5°C and a condensation pressure of 3000 kPa. Find the amount of liquid water removed and the heat transfer in the cooling process. How much compressor work is needed? What is the final air exit temperature and relative humidity?

Solution:
This set-up has a standard refrigeration cycle with R-410A. This cycle and the air flow interacts through the two heat transfer processes. The cooling of the air is provided by the refrigeration cycle and thus requires an amount of work that depends on the cycle COP.

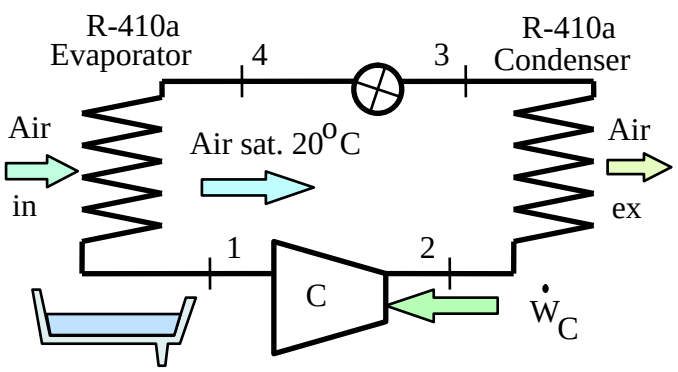
Refrigeration cycle:

State 1: $x = 1$ $h_1 = 277.53$ kJ/kg, $s_1 = 1.0466$ kJ/kg K

State 2: $s_2 = s_1$, $h_2 = 318.97$ kJ/kg, $T_2 = 72.9°C$

State 3: $x_3 = 0.0$, $h_3 = h_f = 141.78$ kJ/kg, $(T_3 = 49.07°C)$

State 4: $h_4 = h_3$ and $P_4 = P_1$



$T_1 = –5°C$, $P_2 = 3000$ kPa

Now for the cycle we get

$w_C = h_2 – h_1 = 318.97 – 277.53 = 41.44$ kJ/kg

$q_H = h_2 – h_3 = 318.97 – 141.78 = 177.19$ kJ/kg

$q_L = h_1 – h_4 = 277.53 – 141.78 = 135.75$ kJ/kg

For the air processes let us use the psychrometric chart.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Air inlet: $w_{in} = 0.019$, $\tilde{h}_{in} = 96$ kJ/kg dry air, $T_{dew} = 24^oC > 15^oC$

Air 15: $\phi = 100\%$, $w_{20} = 0.0148$, $\tilde{h}_{20} = 77.5$, $h_f = 83.94$ (B.1.1)

Now do the continuity (for water) and energy equations for the cooling process

$$\dot{m}_{liq} = \dot{m}_{air} (w_{in} - w_{20}) = 0.25 (0.019 - 0.0148) = \mathbf{0.00105\ kg/s}$$

$$\dot{Q}_{cool} = \dot{m}_{air}(\tilde{h}_{in} - \tilde{h}_{20}) - \dot{m}_{liq} h_f = 0.25(96 - 77.5) - 0.00105 \times 83.94$$
$$= \mathbf{4.537\ kW}$$

Now the heater from the R-410A cycle has

$$\dot{Q}_{heat} = \dot{Q}_{cool} (q_H / q_L) = 4.537\ (177.19 / 135.75) = 5.922\ \text{kW}$$

so the compressor work is the balance of the two

$$\dot{W}_C = \dot{Q}_{heat} - \dot{Q}_{cool} = 5.922 - 4.537 = \mathbf{1.385\ kW}$$

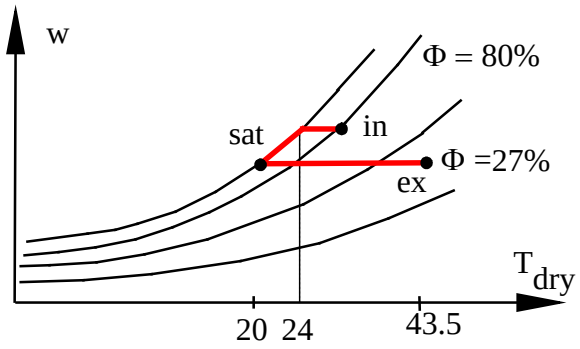
Energy eq. for the air flow being heated

$$\dot{Q}_{heat} = \dot{m}_{air}(\tilde{h}_{ex} - \tilde{h}_{20}) \quad \Rightarrow \quad \tilde{h}_{ex} = \tilde{h}_{20} + \dot{Q}_{heat} / \dot{m}_{air}$$

$$\tilde{h}_{ex} = 77.5 + 5.922 / 0.25 = 101.2\ \text{kJ/kg dry air} \quad \text{and} \quad w_{ex} = w_{20}$$

Locate state in the psychrometric chart

$$T = 43.5^oC \quad \text{and} \quad \phi = 27\%$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.144

The air-conditioning by evaporative cooling in Problem 11.101 is modified by adding a dehumidification process before the water spray cooling process. This dehumidification is achieved as shown in Fig. P11.144 by using a desiccant material, which absorbs water on one side of a rotating drum heat exchanger. The desiccant is regenerated by heating on the other side of the drum to drive the water out. The pressure is 100 kPa everywhere and other properties are on the diagram. Calculate the relative humidity of the cool air supplied to the room at state 4, and the heat transfer per unit mass of air that needs to be supplied to the heater unit.

States as noted on Fig. P11.144, text page 552.

At state 1, 35 °C: $P_{v1} = \phi_1 P_{g1} = 0.30 \times 5.628 = 1.6884$ kPa

$$w_1 = 0.622 \times 1.6884/98.31 = 0.010\ 68$$

At $T_3 = 25$ °C: $w_3 = w_2 = w_1/2 = 0.00534$

Evaporative cooling process to state 4, where $T_4 = 20$°C

Energy as in Eq.11.30: $w_3(h_{v3} - h_{f4}) = C_{P0A}(T_4 - T_3) + w_4 h_{fg4}$

$$0.005\ 34\ (2547.2 - 83.9) = 1.004(20 - 25) + w_4 \times 2454.2$$

$$w_4 = 0.0074 = 0.622 \times P_{v4} / (100 - P_{v4})$$

$P_{v4} = 1.176$ kPa, $\phi_4 = 1.176 / 2.339 =$ **0.503**

Following now the flow back we have $T_5 = 25$ °C, $w_5 = w_4 = 0.0074$

Evaporative cooling process to state 6, where $T_6 = 20$°C

$$w_5(h_{v5} - h_{f6}) = C_{P0A}(T_6 - T_5) + w_6 h_{fg6}$$

$$0.0074(2547.2 - 83.9) = 1.004(20 - 25) + w_6 \times 2454.2$$

$$\Rightarrow \quad w_6 = 0.009\ 47$$

For adiabatic heat exchanger,

$$\dot{m}_{A2} = \dot{m}_{A3} = \dot{m}_{A6} = \dot{m}_{A7} = \dot{m}_A, \qquad \text{Also } w_2 = w_3, \quad w_6 = w_7$$

So now only T_7 is unknown in the energy equation

$$h_{A2} + w_2 h_{v2} + h_{A6} + w_6 h_{v6} = h_{A3} + w_3 h_{v3} + h_{A7} + w_7 h_{v7}$$

or

$$C_{P0A} T_7 + w_6(h_{v7} - h_{v6}) = C_{P0A}(T_2 + T_6 - T_3) + w_2(h_{v2} - h_{v3})$$

$$1.004\ T_7 + 0.009\ 47(h_{v7} - 2538.1) = 1.004(60 + 20 - 25)$$

$$+ 0.005\ 34(2609.6 - 2547.2) = 55.526$$

By trial and error, $T_7 = 54.7$ °C, $h_{v7} = 2600.3$ kJ/kg

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

For the heater 7-8, $w_8 = w_7$,

$$\dot{Q}/\dot{m}_A = C_{P0A}(T_8 - T_7) + w_7(h_{v8} - h_{v7})$$

$$= 1.004(80 - 54.7) + 0.009\,47(2643.7 - 2600.3) = \mathbf{25.8\ kJ/kg\ dry\ air}$$

11.145E

If oxygen is 21% by mole of air, what is the oxygen state (P, T, v) in a room at 540 R, 15 psia of total volume 2000 ft^3?

The temperature is 540 R,
The partial pressure is $P_{O2} = yP_{tot} = 0.21 \times 15$ psia = 3.15 psia.
At this T, P:

$$v = RT/P = \frac{48.28 \times 540}{3.15 \times 144} \frac{\text{(ft-lbf/lbm R)} \times \text{R}}{\text{(lbf/in}^2\text{) (in/ft)}^2} = 57.48 \text{ ft}^3\text{/lbm}$$

Remark: If we found the oxygen mass then $m_{O2}v_{O2} = V = 2000$ ft^3

11.146E

A flow of oxygen and one of nitrogen, both 540 R, are mixed to produce 1 lbm/s air at 540 R, 15 psia. What are the mass and volume flow rates of each line?

We assume air has mole fraction of oxygen 0.21 and nitrogen 0.79.

For the mixture, $M = 0.21 \times 32 + 0.79 \times 28.013 = 28.85$

For O_2 , $c = 0.21 \times 32 / 28.85 = 0.2329$

For N_2 , $c = 0.79 \times 28.013 / 28.85 = 0.7671$

Since the total flow out is 1 lbm/s, these are the component flows in lbm/s.
Volume flow of O_2 in is

$$\dot{V} = c\dot{m}v = c\dot{m}\frac{RT}{P} = 0.2329 \times 1 \text{ lbm/s} \times \frac{48.28 \text{ lbf-ft/lbm-R} \times 540 \text{ R}}{15 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2}$$

$$= \mathbf{2.81\ ft^3/s}$$

Volume flow of N_2 in is

$$\dot{V} = c\dot{m}v = c\dot{m}\frac{RT}{P} = 0.7671 \times 1 \text{ lbm/s} \times \frac{55.15 \text{ lbf-ft/lbm-R} \times 540 \text{ R}}{15 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2}$$

$$= \mathbf{10.58\ ft^3/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.147E

A gas mixture at 250 F, 18 lbf/in.^{2} is 50% N_2, 30% H_2O and 20% O_2 on a mole basis. Find the mass fractions, the mixture gas constant and the volume for 10 lbm of mixture.

Solution:

The conversion follows the definitions and identities:

From Eq.11.3: $c_i = y_i M_i / \sum y_j M_j$

From Eq.11.5:

$$M_{mix} = \sum y_j M_j = 0.5 \times 28.013 + 0.3 \times 18.015 + 0.2 \times 31.999$$
$$= 14.0065 + 5.4045 + 6.3998 = 25.811$$

$c_{N2} = 14.0065 / 25.811 = 0.5427$, $c_{H2O} = 5.4045 / 25.811 = 0.2094$

$c_{O2} = 6.3998 / 25.811 = 0.2479$, sums to 1 OK

From Eq.11.14 and $\bar{R} = 1545.36$ lbf-ft/lbmol-R:

$$R_{mix} = \bar{R}/M_{mix} = 1545.36 / 25.811 = \mathbf{59.87\ lbf\ ft/lbm\ R}$$

$$V = mR_{mix}\, T/P = 10\ \text{lbm} \times \frac{59.87\ \text{lbf-ft/lbm-R} \times 710\ \text{R}}{18\ \text{psi} \times 144\ \text{in}^2/\text{ft}^2}$$

$$= \mathbf{164\ ft^3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.148E

In a car engine gasoline (assume octane C_8H_{18}) is evaporated and then mixed with air in a ratio of 1:15 by mass. In the cylinder the mixture is at 110 psia, 1200 R when the spark fires. For that time find the partial pressure of the octane and the specific volume of the mixture.

Assuming ideal gas the partial pressure is $P_i = y_i P$ and $c_{C8H18} = 1/16 = 0.0625$

From Eq. 11.4: $y_i = [c_i / M_i] / \sum c_j/M_j$

$$y_{C8H18} = \frac{0.0625/114.232}{0.0625/114.232 + 0.9375/28.97} = 0.008186$$

$$P_{C8H18} = 0.008186 \times 110 = \mathbf{0.90\ psia}$$

The gas constant from Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.0625 \times 13.53 + 0.9375 \times 53.34 = 50.852 \text{ ft-lbf/lbm-R}$$

$$v_{mix} = R_{mix} T/P = \frac{50.852 \text{ lbf-ft/lbm-R} \times 1200 \text{ R}}{110 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2} = \mathbf{3.852\ ft^3/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.149E

A diesel engine sprays fuel (assume n-Dodecane $C_{12}H_{26}$, M = 170.34 lbm/lbmol) into the combustion chamber already filled with in an amount of 1 mol fuel per 88 mol air. Find the fuel fraction on a mass basis and the fuel mass for a chamber that is 0.07 ft^3 at 1400 R and total pressure of 600 psia.

From Eq. 11.3: $c_i = y_i M_i / \sum y_j M_j$

$$c_{fuel} = \frac{(1/89) \times 170.34}{(1/89) \times 170.34 + (88/89)\, 28.97} = \mathbf{0.06263}$$

Use ideal gas for the fuel vapor

$$m_{fuel} = \frac{P_{fuel} V}{R_{fuel} T} = \frac{(1/89) \times 600 \text{ psi} \times 0.07 \text{ ft}^3 \times 144 \text{ (in/ft)}^2}{(1545.4/170.34) \text{ ft-lbf/lbm-R} \times 1400 \text{ R}} = \mathbf{0.00535 \text{ lbm}}$$

We could also have done the total mass and then used the mass fraction

Eq.11.5: $M_{mix} = \sum y_j M_j = (1/89) \times 170.34 + (88/89) \times 28.97 = 30.558$

$R_{mix} = \bar{R}/M_{mix} = 1545.4 / 30.558 = 50.5727$ ft-lbf/lbm-R

$$m = PV / R_{mix} T = \frac{600 \text{ psi} \times 0.07 \text{ ft}^3 \times 144 \text{ (in/ft)}^2}{50.5727 \text{ ft-lbf/lbm-R} \times 1400 \text{ R}} = 0.08542 \text{ lbm}$$

$m_{fuel} = c_{fuel}\, m = 0.06263 \times 0.08542$ lbm $= 0.00535$ lbm

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.150E

A new refrigerant R-410A is a mixture of R-32 and R-125 in a 1:1 mass ratio. What is the overall molecular weight, the gas constant and the ratio of specific heats for such a mixture?

Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.5 \times 29.7 + 0.5 \times 12.87 = \mathbf{21.285\ ft\text{-}lbf/lbm\ R}$$

Eq.11.23:

$$C_{P\ mix} = \sum c_i\ C_{P\ i} = 0.5 \times 0.196 + 0.5 \times 0.189 = 0.1925\ \text{Btu/lbm R}$$

Eq.11.21:

$$C_{V\ mix} = \sum c_i C_{V\ i} = 0.5 \times 0.158 + 0.5 \times 0.172 = 0.165\ \text{Btu/lbm R}$$

$$(= C_{P\ mix} - R_{mix})$$

$$k_{mix} = C_{P\ mix} / C_{V\ mix} = 0.1925 / 0.165 = \mathbf{1.1667}$$

$$M = \sum y_j M_j = = 1 / \Sigma\ (c_j / M_j) = \frac{1}{\frac{0.5}{52.024} + \frac{0.5}{120.022}} = \mathbf{72.586}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.151E

Do the previous problem for R-507a, which is a 1:1 mass ratio of R-125 and R-143a. The refrigerant R-143a has molecular mass of 84.041 lbm/lbmol, and C_P = 0.222 Btu/lbm-R.

For R-143a: R = 1545.36/84.041 = 18.388 ft-lbf/lbm-R

$C_V = C_P - R = 0.222 - 18.388/778.17 = 0.1984$ Btu/lbm-R

Eq.11.15:

$$R_{mix} = \sum c_i R_i = 0.5 \times 12.87 + 0.5 \times 18.388 = \mathbf{15.629\ ft\text{-}lbf/lbm\ R}$$

Eq.11.23:

$$C_{P\,mix} = \sum c_i\, C_{P\,i} = 0.5 \times 0.189 + 0.5 \times 0.222 = 0.2055 \text{ Btu/lbm R}$$

Eq.11.21:

$$C_{V\,mix} = \sum c_i C_{V\,i} = 0.5 \times 0.172 + 0.5 \times 0.1984 = 0.1852 \text{ Btu/lbm R}$$

$$(= C_{P\,mix} - R_{mix})$$

$$k_{mix} = C_{P\,mix} / C_{V\,mix} = 0.2055 / 0.1852 = \mathbf{1.1096}$$

$$M = \sum y_j M_j = = 1 / \Sigma (c_j / M_j) = \frac{1}{\frac{0.5}{84.041} + \frac{0.5}{120.022}} = \mathbf{98.86}$$

11.152E

A rigid container has 1 lbm CO_2 at 540 R and 1 lbm argon at 720 R both at 20 psia. Now they are allowed to mix without any heat transfer. What is final T, P?

No Q, No W so the energy equation gives constant U

Energy Eq.:

$$U_2 - U_1 = 0 = m_{CO2}(u_2 - u_1)_{CO2} + m_{Ar}(u_2 - u_1)_{Ar}$$

$$= m_{CO2}C_{v\,CO2}(T_2 - T_1)_{CO2} + m_{Ar}C_{v\,Ar}(T_2 - T_1)_{Ar}$$

$$= (1\times0.201 + 1\times0.124)\ \text{Btu/R} \times T_2 - (1\times0.201\times540 + 1\times0.124\times720)\ \text{Btu}$$

T_2 = **608.7 R**,

Volume from the beginning state

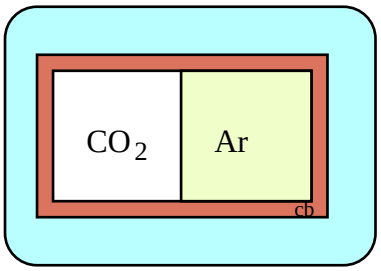
$$V = V_1 = V_{CO2} + V_{Ar} = m_{CO2}R_{CO2}T_{CO2}/P + m_{Ar}R_{Ar}T_{Ar}/P$$

$$= [1\times35.10\times540/20 + 1\times38.68\times720/20\ ]/144 = 16.25\ \text{ft}^3$$

Pressure from ideal gas law and Eq.11.15 for R

$$P_2 = mRT/V$$

$$= (1\times35.10 + 1\times38.68) \times 608.7/(16.25 \times144) = \textbf{19.2 psia}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.153E

A flow of 1 lbm/s argon at 540 R and another flow of 1 lbm/s CO_2 at 2800 R both at 20 psia are mixed without any heat transfer. What is the exit T, P?

No work implies no pressure change for a simple flow.

P_e = **20 psia**

The energy equation becomes

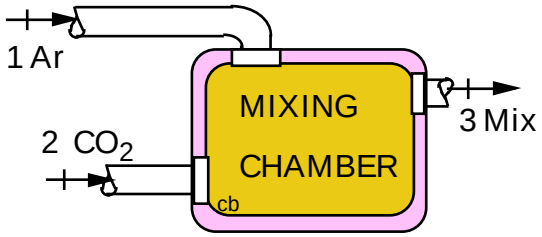
$$\dot{m}h_i = \dot{m}h_e = (\dot{m}h_i)_{Ar} + (\dot{m}h_i)_{CO2} = (\dot{m}h_e)_{Ar} + (\dot{m}h_e)_{CO2}$$

$$\Rightarrow \quad \dot{m}_{CO2}C_{p\,CO2}(T_e - T_i)_{CO2} + \dot{m}_{Ar}C_{p\,Ar}(T_e - T_i)_{Ar} = 0$$

$$\Rightarrow \quad \dot{m}_{Ar}C_{p\,Ar}T_i + \dot{m}_{CO2}C_{p\,CO2}T_i = [\dot{m}_{Ar}C_{p\,Ar} + \dot{m}_{CO2}C_{p\,CO2}]\,T_e$$

$$(1 \times 0.124 \times 540 + 1 \times 0.201 \times 2800)\ \text{Btu/s} = (1 \times 0.124 + 1 \times 0.201)\ \text{Btu/s-R} \times T_e$$

T_e = **1937.7 R**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.154E

Repeat the previous problem using variable specific heats.

A flow of 1 lbm/s argon at 540 R and another flow of 1 lbm/s CO_2 at 2800 R both at 20 psia are mixed without any heat transfer. What is the exit T, P?

No work implies no pressure change for a simple flow.

$$P_e = \mathbf{20\ psia}$$

The energy equation becomes

$$\dot{m}h_i = \dot{m}h_e = (\dot{m}h_i)_{Ar} + (\dot{m}h_i)_{CO2} = (\dot{m}h_e)_{Ar} + (\dot{m}h_e)_{CO2}$$

$$\Rightarrow \quad \dot{m}_{CO2}(h_e - h_i)_{CO2} + \dot{m}_{Ar}C_{p\,Ar}(T_e - T_i)_{Ar} = 0$$

$$\Rightarrow \quad \dot{m}_{Ar}C_{p\,Ar}T_i + \dot{m}_{CO2}h_i = \dot{m}_{Ar}C_{p\,Ar}\,T_e + \dot{m}_{CO2}\,h_{eCO2}$$

$$1 \times 0.124 \times 540 + 1 \times 27\,926/44.01 = 701.5 \text{ Btu/s}$$

$$= 1 \text{ lbm/s} \times (0.124 \text{ Btu/lbm-R } T_e + h_{eCO2})$$

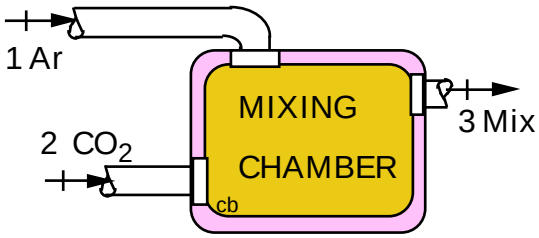
Trial and error on RHS using Table F.6 for h_{eCO2}

T_e = 2000 R: RHS = 16982/44.01 + 0.124 × 2000 = 633.87 too small

T_e = 2200 R: RHS = 19659/44.01 + 0.124 × 2200 = 719.494 too large

Final interpolation

$$T_e = 2000 + 200\,\frac{701.5 - 633.87}{719.494 - 633.87} = \mathbf{2158\ R}\ ;$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.155E

A pipe flows 0.1 lbm/s mixture with mass fractions of 40% CO_2 and 60% N_2 at 60 lbf/in.^{2}, 540 R. Heating tape is wrapped around a section of pipe with insulation added and 2 Btu/s electrical power is heating the pipe flow. Find the mixture exit temperature.

Solution:

C.V. Pipe heating section. Assume no heat loss to the outside, ideal gases.

Energy Eq.: $\dot{Q} = \dot{m}(h_e - h_i) = \dot{m}C_{P\,mix}(T_e - T_i)$

From Eq.11.23

$$C_{P\,mix} = \sum c_i\, C_{P\,i} = 0.4 \times 0.201 + 0.6 \times 0.249 = 0.23 \text{ Btu/lbm R}$$

Substitute into energy equation and solve for exit temperature

$$T_e = T_i + \dot{Q} / \dot{m}C_{P\,MIX} = 540 \text{ R} + \frac{2 \text{ Btu/s}}{0.1 \text{ lbm/s} \times 0.23 \text{ Btu/lbm R}} = \mathbf{626.9\ R}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.156E

An insulated gas turbine receives a mixture of 10% CO_2, 10% H_2O and 80% N_2 on a mass basis at 1800 R, 75 lbf/in.^{2}. The volume flow rate is 70 ft^3/s and its exhaust is at 1300 R, 15 lbf/in.^{2}. Find the power output in Btu/s using constant specific heat from F.4 at 540 R.

C.V. Turbine, Steady, 1 inlet, 1 exit flow with an ideal gas mixture, q = 0.

Energy Eq.: $\dot{W}_T = \dot{m}(h_i - h_e) = \dot{n}(\bar{h}_i - \bar{h}_e) = \dot{n}\bar{C}_{P\,mix}(T_i - T_e)$

$$PV = n\bar{R}T \quad => \quad \dot{n} = \frac{\dot{P}\dot{V}}{\bar{R}T} = \frac{75 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 70 \text{ ft}^3/\text{s}}{1545.4 \text{ lbf-ft/lbmol-R} \times 1800 \text{ R}} = 0.272 \text{ lbmol/s}$$

$$\bar{C}_{P\,mix} = \sum y_i \bar{C}_i = 0.1 \times 44.01 \times 0.201 + 0.1 \times 18.015 \times 0.447$$
$$+ 0.8 \times 28.013 \times 0.249 = 7.27 \text{ Btu/lbmol R}$$

$\dot{W}_T = 0.272$ lbmol/s $\times$ 7.27 Btu/lbmol-R $\times$ (1800 – 1300) R = **988.7 Btu/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.157E

Solve Problem 11.156 using the values of enthalpy from Table F.6

C.V. Turbine, Steady, 1 inlet, 1 exit flow with an ideal gas mixture, q = 0.

Energy Eq.: $\dot{W}_T = \dot{m}(h_i - h_e) = \dot{n}(\bar{h}_i - \bar{h}_e)$

$$PV = n\bar{R}T \quad => \quad \dot{n} = \frac{P\dot{V}}{\bar{R}T} = \frac{75 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 70 \text{ ft}^3/\text{s}}{1545.4 \text{ lbf-ft/lbmol-R} \times 1800 \text{ R}} = 0.272 \text{ lbmol/s}$$

$$\dot{W}_T = 0.272 \text{ lbmol/s} \times [0.1(14\,358 - 8121) + 0.1(11\,178 - 6468.5)$$
$$+ 0.8(9227 - 5431)] \text{ Btu/lbmol}$$
$$= \mathbf{1123.7 \text{ Btu/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.158E

A piston cylinder device contains 0.3 lbm of a mixture of 40% methane and 60% propane by mass at 540 R and 15 psia. The gas is now slowly compressed in an isothermal (T = constant) process to a final pressure of 40 psia. Show the process in a P-V diagram and find both the work and heat transfer in the process.

Solution:

C.V. Mixture of methane and propane, this is a control mass.

Assume methane & propane are ideal gases at these conditions.

Energy Eq.3.5: $m(u_2 - u_1) = {}_1Q_2 - {}_1W_2$

Property from Eq.11.15

$$R_{mix} = 0.4\, R_{CH4} + 0.6\, R_{C3H8}$$

$$= 0.4 \times 96.35 + 0.6 \times 35.04 = 59.564 \frac{\text{ft-lbf}}{\text{lbm R}} = 0.07656 \frac{\text{Btu}}{\text{lbm R}}$$

Process: T = constant & ideal gas =>

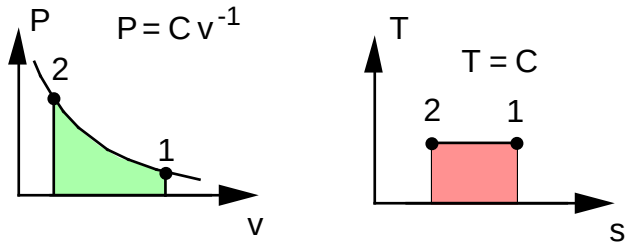
$${}_1W_2 = \int P\, dV = mR_{mix}T \int (1/V)dV = mR_{mix}T \ln (V_2/V_1)$$

$$= mR_{mix}T \ln (P_1/P_2)$$

$$= 0.3 \text{ lbm} \times 0.07656 \frac{\text{Btu}}{\text{lbm R}} \times 540 \text{ R} \ln (15/40) = \mathbf{-12.16\ Btu}$$

Now heat transfer from the energy equation where we notice that u is a constant (ideal gas and constant T) so

$${}_1Q_2 = m(u_2 - u_1) + {}_1W_2 = {}_1W_2 = \mathbf{-12.16\ Btu}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.159E

Two insulated tanks A and B are connected by a valve. Tank A has a volume of 30 ft^3 and initially contains argon at 50 $lbf/in.^2$, 50 F. Tank B has a volume of 60 ft^3 and initially contains ethane at 30 $lbf/in.^2$, 120 F. The valve is opened and remains open until the resulting gas mixture comes to a uniform state. Find the final pressure and temperature.

Energy eq.: $U_2 - U_1 = 0 = n_{Ar}\bar{C}_{V0}(T_2 - T_{A1}) + n_{C_2H_6}\bar{C}_{VO}(T_2 - T_{B1})$

$$n_{Ar} = P_{A1}V_A/\bar{R}T_{A1} = \frac{50\ psi \times 144\ in^2/ft^2 \times 30\ ft^3}{1545\ lbf\text{-}ft/lbmol\text{-}R \times 509.7\ R} = 0.2743\ lbmol$$

$$n_{C_2H_6} = P_{B1}V_B/\bar{R}T_{B1} = \frac{30\ psi \times 144\ in^2/ft^2 \times 60\ ft^3}{1545\ lbf\text{-}ft/lbmol\text{-}R \times 579.7\ R} = 0.2894\ lbmol$$

$$n_2 = n_{Ar} + n_{C_2H_6} = 0.5637\ lbmol$$

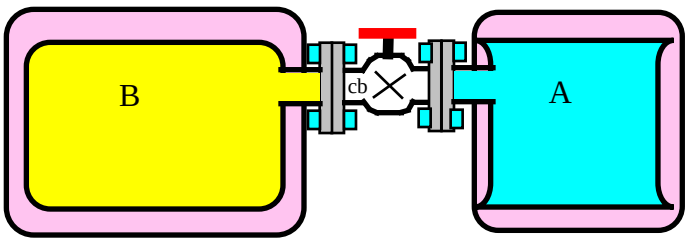
Substitute this into the energy equation

$$0.2743 \times 39.948 \times 0.0756\ (T_2 - 509.7)$$

$$+ 0.2894 \times 30.07 \times 0.361\ (T_2 - 509.7) = 0$$

Solving, $T_2 =$ **565.1 R**

$$P_2 = n_2\bar{R}T_2/(V_A + V_B) = \frac{0.5637 \times 1545 \times 565.1}{90 \times 144} = \mathbf{38\ lbf/in^2}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.160E

A mixture of 4 lbm oxygen and 4 lbm of argon is in an insulated piston cylinder arrangement at 14.7 lbf/in.^{2}, 540 R. The piston now compresses the mixture to half its initial volume. Find the final pressure, temperature and the piston work.

Since $T_1 >> T_C$ assume ideal gases.

Energy Eq.: $u_2 - u_1 = {}_1q_2 - {}_1w_2 = - {}_1w_2$; Entropy Eq.: $s_2 - s_1 = 0$

Process Eq.: Pv^k = constant, $v_2 = v_1/2$

$$P_2 = P_1(v_1/v_2)^k = P_1(2)^k; \; T_2 = T_1(v_1/v_2)^{k-1} = T_1(2)^{k-1}$$

Find k_{mix} to get P_2, T_2 and $C_{v\,mix}$ for $u_2 - u_1$

$R_{mix} = \Sigma c_i R_i = (0.5 \times 48.28 + 0.5 \times 38.68)/778 = 0.055887$ Btu/lbm R

$C_{Pmix} = \Sigma c_i C_{Pi} = 0.5 \times 0.219 + 0.5 \times 0.1253 = 0.17215$ Btu/lbm R

$C_{vmix} = C_{Pmix} - R_{mix} = 0.11626$ Btu/lbm-R, $k_{mix} = C_{Pmix}/C_{vmix} = 1.4807$

Eq.6.25: $P_2 = 14.7(2)^{1.4805} =$ **41.03 lbf/in^2**,

Eq.6.24: $T_2 = 540 \times 2^{0.4805} =$ **753.5 R**

Work from the energy equation

$${}_1w_2 = u_1 - u_2 = C_v(T_1 - T_2) = 0.11626\,(540 - 753.5)$$

$$= -24.82 \text{ Btu/lbm}$$

$${}_1W_2 = m_{tot}\,{}_1w_2 = 8\,(-24.82) = \mathbf{-198.6\ Btu}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.161E

A flow of gas A and a flow of gas B are mixed in a 1:2 mole ratio with same T. What is the entropy generation per lbmole flow out?

For this the mole fractions are,

$$y_A = n_A/n_{tot} = 1/3; \quad y_B = n_B/n_{tot} = 2/3$$

Eq. 11.19: $\Delta S = - \bar{R}[(1/3)\ln(1/3) + (2/3)\ln(2/3)] = + 0.63651\ \bar{R}$

$= 0.63651 \times 1.98589 =$ **1.264 Btu/lbmol-R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.162E

A rigid container has 1 lbm argon at 540 R and 1 lbm argon at 720 R both at 20 psia. Now they are allowed to mix without any external heat transfer. What is final T, P? Is any s generated?

Energy Eq.: $U_2 - U_1 = 0 = 2mu_2 - mu_{1a} - mu_{1b} = mC_v(2T_2 - T_{1a} - T_{1b})$

$$T_2 = (T_{1a} + T_{1b})/2 = \mathbf{630\ R},$$

Process Eq.: V = constant =>

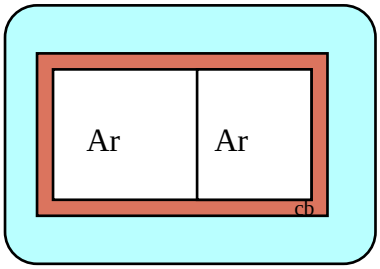
$$P_2V = 2mRT_2 = mR(T_{1a} + T_{1b}) = P_1V_{1a} + P_1V_{1b} = P_1V$$

$$P_2 = P_1 = \mathbf{20\ psia}$$

ΔS due to temp changes only , not P

$$\Delta S = m(s_2 - s_{1a}) + m(s_2 - s_{1b}) = mC\,[\ln(T_2/T_{1a}) + \ln(T_2/T_{1b})]$$

$$= 1 \times 0.124 \left[\ln\frac{630}{540} + \ln\frac{630}{720} \right] = \mathbf{0.00256\ Btu/R}$$



Why did we not account for partial pressures? Since we mix argon with argon there is no entropy generation due to mixing and no partial pressure.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.163E

What is the rate of entropy increase in problem 11.153E?

Using Eq. 11.4, the mole fraction of CO_2 in the mixture is

$$y_{CO2} = \frac{c_{CO2}/M_{CO2}}{c_{CO2}/M_{CO2} + c_{Ar}/M_{Ar}} = \frac{0.5 / 44.01}{0.5 / 39.948 + 0.5 / 44.01} = 0.4758$$

$$y_{Ar} = 1 - y_{CO2} = 0.5242$$

The energy equation becomes

$$\dot{m}h_i = \dot{m}h_e = (\dot{m}h_i)_{Ar} + (\dot{m}h_i)_{CO2} = (\dot{m}h_e)_{Ar} + (\dot{m}h_e)_{CO2}$$

$$\Rightarrow \quad \dot{m}_{CO2}C_{p\,CO2}(T_e - T_i)_{CO2} + \dot{m}_{Ar}C_{p\,Ar}(T_e - T_i)_{Ar} = 0$$

$$\Rightarrow \quad \dot{m}_{Ar}C_{p\,Ar}T_i + \dot{m}_{CO2}C_{p\,CO2}T_i = [\dot{m}_{Ar}C_{p\,Ar} + \dot{m}_{CO2}C_{p\,CO2}]\,T_e$$

$$(1 \times 0.124 \times 540 + 1 \times 0.201 \times 2800)\ \text{Btu/s} = (1 \times 0.124 + 1 \times 0.201)\ \text{Btu/s-R} \times T_e$$

$$T_e = 1937.7\ \text{R}$$

From Eqs. 11.16 and 11.17, from the two inlet states to state 2,

$$\dot{m}(s_e - s_i) = 1 \times [0.124 \ln(\frac{1937.7}{540}) - \frac{38.68}{778} \ln (\frac{0.5242 \times 20}{20})]$$

$$+1 \times [0.201 \ln(\frac{1937.7}{2800}) - \frac{35.10}{778} \ln (\frac{0.4758 \times 20}{20})] = \mathbf{0.15\ Btu/s\ R}$$

The increase is also the entropy generation as there is no heat transfer.

11.164E

Find the entropy generation for the process in Problem 11.159E.

Energy eq. $U_2 - U_1 = 0 = n_{Ar}\bar{C}_{V0}(T_2 - T_{A1}) + n_{C_2H_6}\bar{C}_{VO}(T_2 - T_{B1})$

$$n_{Ar} = P_{A1}V_A/\bar{R}T_{A1} = \frac{50 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 30 \text{ ft}^3}{1545 \text{ lbf-ft/lbmol-R} \times 509.7 \text{ R}} = 0.2743 \text{ lbmol}$$

$$n_{C_2H_6} = P_{B1}V_B/\bar{R}T_{B1} = \frac{30 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 60 \text{ ft}^3}{1545 \text{ lbf-ft/lbmol-R} \times 579.7 \text{ R}} = 0.2894 \text{ lbmol}$$

$$n_2 = n_{Ar} + n_{C_2H_6} = 0.5637 \text{ lbmol}$$

Substitute into energy equation

$$0.2743 \times 39.948 \times 0.0756 (T_2 - 509.7) + 0.2894 \times 30.07 \times 0.361 (T_2 - 509.7) = 0$$

Solving, $T_2 = 565.1$ R

$$P_2 = n_2\bar{R}T_2/(V_A + V_B) = \frac{0.5637 \times 1545 \times 565.1}{90 \times 144} = 38 \text{ lbf/in}^2$$

$$\Delta S_{SURR} = 0 \quad \rightarrow \Delta S_{gen} = \Delta S_{SYS} = n_{Ar}\Delta\bar{S}_{Ar} + n_{C_2H_6}\Delta\bar{S}_{C_2H_6}$$

$$y_{Ar} = 0.2743/0.5637 = 0.4866$$

$$\Delta\bar{S}_{Ar} = \bar{C}_{P\,Ar} \ln\frac{T_2}{T_{A1}} - \bar{R} \ln\frac{y_{Ar}P_2}{P_{A1}}$$

$$= 39.948 \times 0.1253 \ln\frac{565.1}{509.7} - \frac{1545}{778} \ln\frac{0.4866 \times 38}{50} = 2.4919 \text{ Btu/lbmol R}$$

$$\Delta\bar{S}_{C_2H_6} = \bar{C}_{C_2H_6} \ln\frac{T_2}{T_{B1}} - \bar{R} \ln\frac{y_{C_2H_6}P_2}{P_{B1}}$$

$$= 30.07 \times 0.427 \ln\frac{565.1}{579.7} - \frac{1545}{778} \ln\frac{0.5134 \times 38}{30}$$

$$= 0.5270 \text{ Btu/lbmol R}$$

$$\Delta S_{gen} = 0.2743 \times 2.4919 + 0.2894 \times 0.5270 = \mathbf{0.836 \text{ Btu/R}}$$

11.165E

Carbon dioxide gas at 580 R is mixed with nitrogen at 500 R in an insulated mixing chamber. Both flows are at 14.7 lbf/in.^{2} and the mole ratio of carbon dioxide to nitrogen is 2:1. Find the exit temperature and the total entropy generation per mole of the exit mixture.

CV mixing chamber, steady flow. The inlet ratio is $\dot{n}_{CO_2} = 2\,\dot{n}_{N_2}$ and assume no external heat transfer, no work involved.

Continuity: $\dot{n}_{CO_2} + 2\dot{n}_{N_2} = \dot{n}_{ex} = 3\dot{n}_{N_2}$;

Energy Eq.: $\dot{n}_{N_2}(\bar{h}_{N_2} + 2\bar{h}_{CO_2}) = 3\dot{n}_{N_2}\bar{h}_{mix\ ex}$

Take 540 R as reference and write $\bar{h} = \bar{h}_{540} + \bar{C}_{Pmix}(T\text{-}540)$.

$$\bar{C}_{P\,N_2}(T_{i\,N_2}\text{-}540) + 2\bar{C}_{P\,CO_2}(T_{i\,CO_2}\text{-}540) = 3\bar{C}_{P\,mix}(T_{mix\ ex}\text{-}540)$$

$$\bar{C}_{P\,mix} = \sum y_i \bar{C}_{P\,i} = (29.178 + 2\times 37.05)/3 = 8.2718 \ \text{Btu/lbmol R}$$

$$3\bar{C}_{P\,mix}T_{mix\ ex} = \bar{C}_{P\,N_2}T_{i\,N_2} + 2\bar{C}_{P\,CO_2}T_{i\,CO_2} = 13\,837 \ \text{Btu/lbmol}$$

$$T_{mix\ ex} = 557.6 \ \text{R};$$

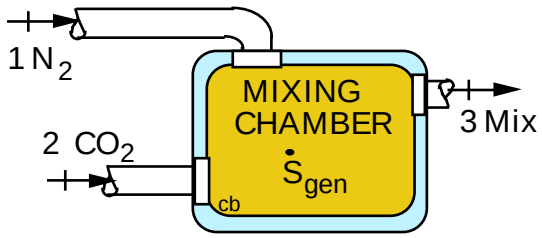
Partial pressures are total pressure times molefraction

$$P_{ex\,N_2} = P_{tot}/3; \quad P_{ex\,CO_2} = 2P_{tot}/3$$

$$\dot{S}_{gen} = \dot{n}_{ex}\bar{s}_{ex} - (\dot{n}\bar{s})_{iCO_2} - (\dot{n}\bar{s})_{iN_2} = \dot{n}_{N_2}(\bar{s}_e - \bar{s}_i)_{N_2} + 2\dot{n}_{N_2}(\bar{s}_e - \bar{s}_i)_{CO_2}$$

$$\dot{S}_{gen}/\dot{n}_{N_2} = \bar{C}_{PN_2}\ln\frac{T_{ex}}{T_{iN_2}} - \bar{R}\ln y_{N_2} + 2\bar{C}_{PCO_2}\ln\frac{T_{ex}}{T_{iCO_2}} - 2\,\bar{R}\ln y_{CO_2}$$

$$= 0.7575 + 2.1817 - 0.7038 + 1.6104 = \mathbf{3.846\ Btu/lbmol\ N_2\ R}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.166E

A steady flow 0.6 lbm/s of 60% carbon dioxide and 40% water mixture by mass at 2200 R and 30 psia is used in a constant pressure heat exchanger where 300 Btu/s is extracted from the flow. Find the exit temperature and rate of change in entropy using Table F.4

Solution:

C.V. Heat exchanger, Steady, 1 inlet, 1 exit, no work.

Continuity Eq.: $c_{CO2} = 0.6$; $c_{H2O} = 0.4$

Energy Eq.: $\dot{Q} = \dot{m}(h_e - h_i) \approx \dot{m}\, C_P\, (T_e - T_i)$ => $T_e = T_i + \dot{Q}/\dot{m}\, C_P$

Inlet state: Table F.4

$$C_P = 0.6 \times 0.201 + 0.4 \times 0.447 = 0.2994 \text{ Btu/lbm-R}$$

Exit state: $T_e = T_i + \dot{Q}/\dot{m}\, C_P = 2200 \text{ R} - \dfrac{300 \text{ Btu/s}}{0.6 \text{ lbm/s} \times 0.2994 \text{ Btu/lbm-R}}$

$$= \mathbf{530\ R}$$

The rate of change of entropy for the flow is (P is assumed constant)

$$\dot{m}(s_e - s_i) = \dot{m}[s^o_{Te} - s^o_{Ti} - R \ln(P_e/P_i)] = \dot{m}[s^o_{Te} - s^o_{Ti}) \approx \dot{m}\, C_P \ln(T_e/T_i)$$

$$= 0.6 \times 0.2994 \ln(530 / 2200) = \mathbf{-0.256\ Btu/s\text{-}R}$$

The entropy generation rate cannot be estimated unless the average T at which the heat transfer leaves the control volume is known.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.167E

A steady flow 0.6 lbm/s of 60% carbon dioxide and 40% water mixture by mass at 2200 R and 30 psia is used in a constant pressure heat exchanger where 300 Btu/s is extracted from the flow. Find the exit temperature and rate of change in entropy using Table F.6

Solution:

C.V. Heat exchanger, Steady, 1 inlet, 1 exit, no work.

Continuity Eq.: $c_{CO2} = 0.6$; $c_{H2O} = 0.4$

Energy Eq.: $\dot{Q} = \dot{m}(h_e - h_i)$ => $h_e = h_i + \dot{Q}/\dot{m}$

Inlet state: Table F.6

$h_i = 0.6 \times 19659/44.01 + 0.4 \times 15254/18.015 = 606.71$ Btu/lbm

Exit state: $h_e = h_i + \dot{Q}/\dot{m} = 606.71 - 300/0.6 = 106.71$ Btu/lbm

Trial and error for T with h values from Table F.6

@800 R $h_e = 0.6 \times 2525/44.01 + 0.4 \times 2142/18.015 = 81.984$ Btu/lbm

@1000 R $h_e = 0.6 \times 4655/44.01 + 0.4 \times 3824/18.015 = 148.37$ Btu/lbm

Interpolate to have the right h: **T = 874.5 R**

Entropy Eq.7.8: $\dot{m}s_e = \dot{m}s_i + \dot{Q}/T + \dot{S}_{gen}$

The rate of change of entropy for the flow is (P is assumed constant)

$$\dot{m}(s_e - s_i) = \dot{m}(s^o_{Te} - s^o_{Ti})$$

$$= 0.6[\ 0.6(55.732 - 66.952)/44.01$$

$$+ 0.4(49.019 - 57.605)/18.015\ ]$$

$$= \mathbf{-0.344\ Btu/s\text{-}R}$$

The entropy generation rate cannot be estimated unless the average T at which the heat transfer leaves the control volume is known.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.168E

A mixture of 60% helium and 40% nitrogen by mole enters a turbine at 150 lbf/in.^{2}, 1500 R at a rate of 4 lbm/s. The adiabatic turbine has an exit pressure of 15 lbf/in.^{2} and an isentropic efficiency of 85%. Find the turbine work.

Assume ideal gas mixture and take CV as turbine.

Energy Eq. ideal turbine: $w_{T\,s} = h_i - h_{es}$,

Entropy Eq. ideal turbine: $s_{es} = s_i \quad \Rightarrow \quad T_{es} = T_i(P_e/P_i)^{(k-1)/k}$

Properties from Eq.11.23, 11.15 and 6.23

$$\bar{C}_{P\,mix} = 0.6\times 1.25\times 4.003 + 0.4\times 0.248\times 28.013 = 5.7811 \text{ Btu/lbmol R}$$

$$(k-1)/k = \bar{R}/\bar{C}_{P\,mix} = 1545/(5.7811\times 778) = 0.3435$$

$$M_{mix} = 0.6 \times 4.003 + 0.4 \times 28.013 = 13.607,$$

$$C_P = \bar{C}_P/M_{mix} = 0.4249 \text{ Btu/lbm R}$$

$$T_{es} = 1500 \text{ R } (15/150)^{0.3435} = 680 \text{ R},$$

$$w_{Ts} = C_P(T_i - T_{es}) = 348.4 \text{ Btu/lbm}$$

Then do the actual turbine

$$w_{T\,ac} = \eta w_{Ts} = 296.1 \text{ Btu/lbm}; \quad \dot{W} = \dot{m} w_{Ts} = \mathbf{1184\ Btu/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.169E

A tank has two sides initially separated by a diaphragm. Side A contains 2 lbm of water and side B contains 2.4 lbm of air, both at 68 F, 14.7 lbf/in.^{2}. The diaphragm is now broken and the whole tank is heated to 1100 F by a 1300 F reservoir. Find the final total pressure, heat transfer, and total entropy generation.

C.V. Total tank out to reservoir.

Energy Eq.3.5: $U_2 - U_1 = m_a(u_2 - u_1)_a + m_v(u_2 - u_1)_v = {}_1Q_2$

Entropy Eq.6.37:

$$S_2 - S_1 = m_a(s_2 - s_1)_a + m_v(s_2 - s_1)_v = {}_1Q_2/T_{res} + S_{gen}$$

$V_2 = V_A + V_B = m_v v_{v1} + m_a v_{a1} = 0.0321 + 31.911 = 31.944$ ft^3

Water: $u_1 = 36.08$ Btu/lbm, $s_1 = 0.0708$ Btu.lbm R,

$v_{v2} = V_2/m_v = 15.9718$, $T_2 =>$ Table F.7.2 $P_{2v} = 58.7$ lbf/in^2

$u_2 = 1414.3$ Btu/lbm, $s_2 = 2.011$ Btu/lbm R

Air: $u_1 = 90.05$ Btu/lbm, $u_2 = 278.23$ Btu/lbm,

$s_{T1} = 1.6342$ Btu/lbm R, $s_{T2} = 1.9036$ Btu/lbm R

$v_{a2} = V_2/m_a = 13.3098$, $T_2 =>$ $P_{2a} = mRT_2/V_2 = 43.415$ lbf/in^2

$$P_{2tot} = P_{2v} + P_{2a} = \mathbf{102\ lbf/in^2}$$

${}_1Q_2 = 2(1414.3 - 36.08) + 2.4(278.23 - 90.05) = \mathbf{3208\ Btu}$

$$S_{gen} = 2(2.011 - 0.0708) + 2.4\left[1.9036 - 1.6342 - \frac{53.34}{778} \times \ln\left(\frac{43.415}{14.7}\right)\right] - \frac{3208}{1760}$$

$= 3.8804 + 0.4684 - 1.823 = \mathbf{2.526\ Btu/R}$

11.170E

A 1 lbm/s flow of saturated moist air (relative humidity 100%) at 14.7 psia and 50 F goes through a heat exchanger and comes out at 77 F. What is the exit relative humidity and the how much power is needed?

Solution:

State 1 : $\phi_1 = 1$; $P_v = P_g = 0.178$ psia

Eq.11.28: $w = 0.622\ P_v/P_a = 0.622 \times 0.178/(14.7 - 0.178) = 0.00762$

State 2 : No water added => $w_2 = w_1$ => $P_{v2} = P_{v1}$

$\phi_2 = P_{v2}/P_{g2} = 0.178/0.464 =$ **0.384 or 38 %**

Energy Eq.4.10

$$\dot{Q} = \dot{m}_2 h_2 - \dot{m}_1 h_1 = \dot{m}_a(h_2 - h_1)_{air} + w\dot{m}_a(h_2 - h_1)_{vapor}$$

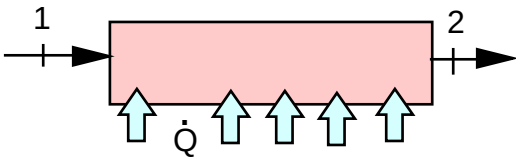
$$\dot{m}_{tot} = \dot{m}_a + \dot{m}_v = \dot{m}_a(1 + w_1)$$

Energy equation with $C_{P\ air}$ from F.4 and h's from F.7.1

$$\dot{Q} = \frac{\dot{m}_{tot}}{1 + w_1} C_{P\ air} (77 - 50) + \frac{\dot{m}_{tot}}{1 + w_1} w\ (h_{g2} - h_{g1})$$

$$= \frac{1}{1.00762} \times 0.24\ (77 - 50) + \frac{1 \times 0.00762}{1.00762} (1090.73 - 1083.29)$$

$$= 6.431 + 0.0563 = \mathbf{6.49\ Btu/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.171E

If I have air at 14.7 psia and a) 15 F b) 115 F and c) 230 F what is the maximum absolute humidity I can have?

Humidity is related to relative humidity (max 100%) and the pressures as in Eq.11.28 where from Eq.11.25 $P_v = \Phi\, P_g$ and $P_a = P_{tot} - P_v$.

$$\omega = 0.622 \frac{P_v}{P_a} = 0.622 \frac{\Phi\, P_g}{P_{tot} - \Phi P_g}$$

a) $P_g = 0.03963$ psia, $\omega = 0.622 \times \dfrac{0.03963}{14.7 - 0.03963} =$ **0.001 68**

b) $P_g = 1.4855$ psia , $\omega = 0.622 \times \dfrac{1.4855}{14.7 - 1.4855} =$ **0.070**

c) $P_g = 20.781$ psia, **no limit** on ω for P > 14.7 psia

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.172E

Consider a volume of 2000 ft^3 that contains an air-water vapor mixture at 14.7 lbf/in.^{2}, 60 F, and 40% relative humidity. Find the mass of water and the humidity ratio. What is the dew point of the mixture?

Air-vap P = 14.7 lbf/in.^{2}, T = 60 F, ϕ = 40%

$P_g = P_{sat60} = 0.256$ lbf/in.^{2}

$P_v = \phi\, P_g = 0.4 \times 0.256 = 0.1024$ lbf/in.^{2}

$$m_{v1} = \frac{P_v V}{R_v T} = \frac{0.1024 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 2000 \text{ ft}^3}{85.76 \text{ lbf-ft/lbm-R} \times 520 \text{ R}} = \mathbf{0.661 \text{ lbm}}$$

$P_a = P_{tot} - P_{v1} = 14.7 - 0.1024 = 14.598$ lbf/in.^{2}

$$m_a = \frac{P_a V}{R_a T} = \frac{14.598 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 2000 \text{ ft}^3}{53.34 \text{ lbf-ft/lbm-R} \times 520 \text{ R}} = 151.576 \text{ lbm}$$

$$w_1 = \frac{m_v}{m_a} = \frac{0.661}{151.576} = \mathbf{0.00436}$$

T_{dew} is T when $P_g(T_{dew}) = 0.1024$ lbf/in.^{2}; T = **35.5 F**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.173E

Consider a 35 ft^3/s flow of atmospheric air at 14.7 psia, 77 F and 80% relative humidity. Assume this flows into a basement room where it cools to 60 F at 14.7 psia. How much liquid will condense out?

Solution:

State 1: $P_g = P_{sat77} = 0.464$ psia => $P_v = \phi P_g = 0.8 \times 0.464 = 0.371$ psia

$$\dot{m}_{v1} = \frac{P_v \dot{V}}{R_v T} = \frac{0.371 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 35 \text{ ft}^3/\text{s}}{85.76 \text{ lbf-ft/lbm-R} \times 536.67 \text{ R}} = 0.0406 \text{ lbm/s}$$

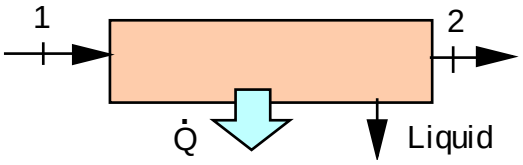
$$w_1 = \frac{\dot{m}_{v1}}{\dot{m}_{A1}} = 0.622 \frac{P_{v1}}{P_{A1}} = 0.622 \frac{0.371}{14.7 - 0.371} = 0.0161$$

$$\dot{m}_{A1} = \frac{\dot{m}_{v1}}{w_1} = \frac{0.0406}{0.0161} = 2.522 \text{ lbm/s} = \dot{m}_{A2} \qquad \text{(continuity for air)}$$

Check for state 2:

$P_{g60F} = 0.256$ psia $< P_{v1}$

so liquid water out.



State 2 is saturated $\phi_2 = 100\%$, $P_{v2} = P_{g2} = 0.256$ psia

$$w_2 = 0.622 \frac{P_{v2}}{P_{A2}} = 0.622 \frac{0.256}{14.7 - 0.256} = 0.0110$$

$$\dot{m}_{v2} = w_2 \dot{m}_{A2} = 0.0110 \times 2.522 = 0.0277 \text{ lbm/s}$$

$$\dot{m}_{liq} = \dot{m}_{v1} - \dot{m}_{v2} = 0.0406 - 0.0277 = \mathbf{0.0129 \text{ lbm/s}}$$

Note that the given volume flow rate at the inlet is not that at the exit. The mass flow rate of dry air is the quantity that is the same at the inlet and exit.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.174E

Consider a 10-ft^3 rigid tank containing an air-water vapor mixture at 14.7 lbf/in.^{2}, 90 F, with a 70% relative humidity. The system is cooled until the water just begins to condense. Determine the final temperature in the tank and the heat transfer for the process.

$P_{v1} = \phi P_{G1} = 0.7 \times 0.6988 = 0.489$ lbf/in^2

Since m_v = const & V = const & also $P_v = P_{G2}$:

$P_{G2} = P_{v1} \times T_2/T_1 = 0.489 \times T_2/549.7$

For T_2 = 80 F: $0.489 \times 539.7/549.7 = 0.4801 \neq 0.5073$ (= P_G at 80 F)

For T_2 = 70 F: $0.489 \times 529.7/549.7 = 0.4712 \neq 0.3632$ (= P_G at 70 F)

interpolating $\rightarrow T_2 =$ **78.0 F**

$$w_2 = w_1 = 0.622 \frac{0.489}{(14.7\text{-}0.489)} = 0.0214$$

$$m_a = \frac{P_{a1} V}{R_a T_1} = \frac{14.211 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2 \times 10 \text{ ft}^3}{53.34 \text{ lbf-ft/lbm-R} \times 549.7 \text{ R}} = 0.698 \text{ lbm}$$

Energy Eq.:

$$_1Q_2 = U_2 - U_1 = m_a(u_{a2} - u_{a1}) + m_v(u_{v2} - u_{v1})$$

$$= m_a[\, C_v (T_{a2} - T_{a1}) + w_1 (u_{v2} - u_{v1}) \,]$$

$$= 0.698 \text{ lbm } [0.171(78 - 90) + 0.0214(1036.3 - 1040.2)] \text{ Btu/lbm}$$

$$= 0.698 \text{ lbm } (-2.135 \text{ Btu/lbm}) = \mathbf{-1.49 \text{ Btu}}$$

11.176E

In the production of ethanol from corn the solids left after fermentation are dried in a continuous flow oven. This process generates a flow of 35 lbm/s moist air, 200 F with 70% relative humidity, which contains some volatile organic compounds and some particles. To remove the organic gasses and the particles, the flow is send to a **thermal oxidicer,** see Fig. P11.82, where natural gas flames brings the mixture to 1500 F. Find the rate of heating by the natural gas burners.

For this problem we will just consider the heating of the gas mixture and due to the exit temperature we will use the ideal gas tables F5 and F6.

Eq.11.25: $P_v = \phi\, P_g = 0.70 \times 11.53 \text{ psia} = 8.07 \text{ psia}$

Eq.11.28: $\omega = 0.622 \dfrac{P_v}{P_{tot} - P_v} = 0.622 \times \dfrac{8.07}{14.7 - 8.07} = 0.757$

Flow: $\dot{m}_{tot} = \dot{m}_a + \dot{m}_v = \dot{m}_a(1 + \omega)$ so

$$\dot{m}_a = \frac{\dot{m}_{tot}}{1 + \omega} = 19.92 \text{ lbm/s}; \quad \dot{m}_v = \dot{m}_{tot} \frac{\omega}{1 + \omega} = 15.08 \text{ lbm/s}$$

Process: Heating => ω is constant => P_v is constant

For ideal gas the enthalpy does not depend on pressure so the energy equation gives the heat transfer as

$$\dot{Q} = \dot{m}_a (h_2 - h_1)_a + \dot{m}_v (h_2 - h_1)_v$$
$$= 19.92 (493.61 - 157.96) + 15.08 (12779 - 996.45)/18.015$$
$$= 6686 + 9863 = \mathbf{16\ 549\ Btu/s}$$

Comment: Notice how much energy is spend on heating the water vapor.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.177E

To save on natural gas use in the previous problem it is suggested to take and cool the mixture and condense out some water before heating it back up. So the flow is cooled from 200 F to 120 F as shown in Fig. P11.83 and the now dryer mixture is heated to 1500 F. Find the amount of water condensed out and the rate of heating by the natural gas burners for this case.

Eq.11.25: $P_v = \phi\, P_g = 0.70 \times 11.53 \text{ psia} = 8.07 \text{ psia}$

Eq.11.28: $\omega = 0.622 \dfrac{P_v}{P_{tot} - P_v} = 0.622 \times \dfrac{8.07}{14.7 - 8.07} = 0.757$

Flow: $\dot{m}_{tot} = \dot{m}_a + \dot{m}_v = \dot{m}_a(1 + \omega)$ so

$$\dot{m}_a = \frac{\dot{m}_{tot}}{1 + \omega} = 19.92 \text{ lbm/s}; \quad \dot{m}_v = \dot{m}_{tot} \frac{\omega}{1 + \omega} = 15.08 \text{ lbm/s}$$

Now cool to 120 F: $P_g = 1.695 \text{ psia} < P_{v1}$ so $\phi_2 = 100\%$, $P_{v2} = 1.695 \text{ psia}$

$$\omega_2 = 0.622 \frac{P_v}{P_{tot} - P_v} = 0.622 \times \frac{1.695}{14.7 - 1.695} = 0.08107$$

$$\dot{m}_{liq} = \dot{m}_a (\omega_1 - \omega_2) = 19.92 (0.757 - 0.08107) = 13.464 \text{ lbm/s}$$

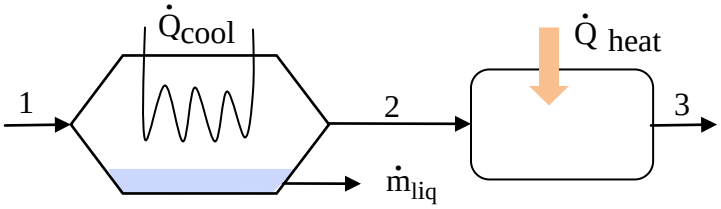
The air flow is not changed so the water vapor flow for heating is

$$\dot{m}_{v2} = \dot{m}_{v1} - \dot{m}_{liq} = 15.08 - 13.464 = 1.616 \text{ lbm/s}$$

Now the energy equation becomes

$$\dot{Q} = \dot{m}_a (h_3 - h_2)_a + \dot{m}_{v2} (h_3 - h_2)_v$$
$$= 19.92 (493.61 - 157.96) + 1.616 (12779 - 996.45)/18.015$$
$$= \mathbf{7743 \text{ Btu/s}}$$

Comment: If you solve the previous problem you find this is only 47% of the heat for the case of no water removal.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.178E

Two moist air streams with 85% relative humidity, both flowing at a rate of 0.2 lbm/s of dry air are mixed in a steady flow setup. One inlet flowstream is at 90 F and the other at 61 F. Find the exit relative humidity.

Solution:

CV mixing chamber.

Continuity Eq. water: $\dot{m}_{air}\, w_1 + \dot{m}_{air}\, w_2 = 2\dot{m}_{air}\, w_{ex}$;

Energy Eq.: $\dot{m}_{air}\, \tilde{h}_1 + \dot{m}_{air}\, \tilde{h}_2 = 2\dot{m}_{air}\, \tilde{h}_{ex}$

Properties from the tables and formulas

$P_{g90} = 0.699$; $P_{v1} = 0.85 \times 0.699 = 0.594$ psia

$w_1 = 0.622 \times 0.594 / (14.7 - 0.594) = 0.0262$

$P_{g61} = 0.2667$; $P_{v2} = 0.85 \times 0.2667 = 0.2267$ psia

$w_2 = 0.622 \times 0.2267 / (14.7 - 0.2267) = 0.00974$

Continuity Eq. water: $w_{ex} = (w_1 + w_2)/2 = 0.018$;

For the energy equation we have $\tilde{h} = h_a + w h_v$ so:

$2\tilde{h}_{ex} - \tilde{h}_1 - \tilde{h}_2 = 0 = 2h_{a\,ex} - h_{a\,1} - h_{a\,2} + 2w_{ex}h_{v\,ex} - w_1 h_{v\,1} - w h_{v\,2}$

we will use constant heat capacity to avoid an iteration on T_{ex}.

$C_{p\,air}(2T_{ex} - T_1 - T_2) + C_{p\,H2O}(2w_{ex}T_{ex} - w_1T_1 - w_2T_2) = 0$

$T_{ex} = [\, C_{p\,air}(T_1 + T_2) + C_{p\,H2O}(w_1T_1 + w_2T_2)\,]/\,[2C_{p\,air} + 2w_{ex}C_{p\,H2O}]$

$= [\, 0.24\,(90 + 61) + 0.447(0.0262 \times 90 + 0.00974 \times 61]/0.4961$

$= 75.7$ F

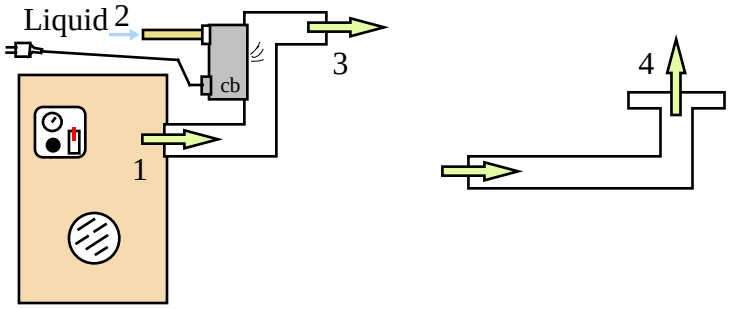
$$P_{v\,ex} = \frac{w_{ex}}{0.622 + w_{ex}} P_{tot} = \frac{0.018}{0.622 + 0.018} 14.7 = 0.413 \text{ psia},$$

$P_{g\,ex} = 0.445$ psia => $\phi = 0.413 / 0.445 =$ **0.93 or 93%**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.179E

A flow of moist air from a domestic furnace, state 1 in Figure P11.100, is at 120 F, 10% relative humidity with a flow rate of 0.1 lbm/s dry air. A small electric heater adds steam at 212 F, 14.7 psia generated from tap water at 60 F. Up in the living room the flow comes out at state 4: 90 F, 60% relative humidity. Find the power needed for the electric heater and the heat transfer to the flow from state 1 to state 4.



State 1: F.7.1: $P_{g1} = 1.695$ psia, $h_{g1} = 1113.54$ Btu/lbm

$$P_{v1} = \phi\, P_{g1} = 0.1 \times 1.695 = 0.1695 \text{ psia}$$

$$w_1 = 0.622 \frac{P_{v1}}{P_{tot} - P_{v1}} = 0.622 \frac{0.1695}{14.7 - 0.1695} = 0.00726$$

Starte 2: $h_f = 28.08$ Btu/lbm ; State 2a: $h_{g\,212} = 1150.49$ Btu/lbm

State 4: $P_{g4} = 0.699$ psia, $h_{g4} = 1100.72$ Btu/lbm

$$P_{v4} = \phi\, P_{g4} = 0.6 \times 0.699 = 0.4194 \text{ psia}$$

$$w_4 = 0.622 \frac{P_{v4}}{P_{tot} - P_{v4}} = 0.622 \frac{0.4194}{14.7 - 0.4194} = 0.0183$$

$$\dot{m}_{liq} = \dot{m}_a (\omega_1 - \omega_4) = 0.1\,(0.0183 - 0.00726) = 0.0011 \text{ lbm/s}$$

Energy Eq. for heater:

$$\dot{Q}_{heater} = \dot{m}_{liq} (h_{out} - h_{in}) = 0.0011\,(1150.49 - 28.08)$$

$$= \mathbf{1.235\ Btu/s = 1.17\ kW}$$

Energy Eq. for line (excluding the heater):

$$\dot{Q}_{line} = \dot{m}_a (h_{a4} + w_4 h_{g4} - h_{a1} - w_1 h_{g1}) - \dot{m}_{liq}\, h_{g\,212}$$

$$= 0.1[\ 0.24(90 - 120) + 0.0183 \times 1100.72 - 0.00726 \times 1113.54\ ]$$

$$- 0.0011 \times 1150.49$$

$$= \mathbf{-0.78\ Btu/s}$$

11.180E

Atmospheric air at 95 F, relative humidity of 10%, is too warm and also too dry. An air conditioner should deliver air at 70 F and 50% relative humidity in the amount of 3600 ft^3 per hour. Sketch a setup to accomplish this, find any amount of liquid (at 68 F) that is needed or discarded and any heat transfer.

CV air conditioner. Check first the two states, inlet 1, exit 2.

In: $P_{g1} = 0.8246$ psia, $h_{g1} = 1102.9$ Btu/lbm, $h_{f,68} = 36.08$ Btu/lbm,

$P_{v1} = \phi_1 P_{g1} = 0.08246$ psia, $w_1 = 0.622\, P_{v1}/(P_{tot}-P_{v1}) = 0.0035$

Ex: $P_{g2} = 0.36324$ psia, $h_{g2} = 1092$ Btu/lbm

$P_{v2} = \phi_2 P_{g2} = 0.1816$ psia, $w_2 = 0.622\, P_{v2}/(P_{tot}-P_{v2}) = 0.00778$

Water must be added ($w_2 > w_1$). Continuity and energy equations

$$\dot{m}_A(1 + w_1) + \dot{m}_{liq} = \dot{m}_A(1 + w_2) \quad \& \quad \dot{m}_A h_{1mix} + \dot{m}_{liq} h_f + \dot{Q}_{CV} = \dot{m}_A h_{2mix}$$

$$\dot{m}_{tot} = P\dot{V}_{tot}/RT = 14.7 \times 3600 \times 144/53.34 \times 529.67 = 270 \text{ lbm/h}$$

$$\dot{m}_A = \dot{m}_{tot}/(1 + w_2) = 267.91 \text{ lbm/h}$$

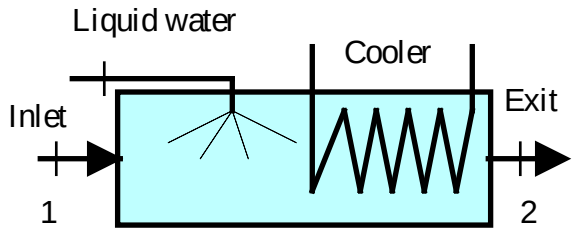
$$\dot{m}_{liq} = \dot{m}_A(w_2 - w_1) = 267.91(0.00778 - 0.0035) = \mathbf{1.147\ lbm/h}$$

$$\dot{Q}_{CV} = \dot{m}_A[C_{p\,a}(T_2 - T_1) + w_2 h_{g2} - w_1 h_{g1}] - \dot{m}_{liq} h_{f,68}$$

$$= 267.91\,[\,0.24(70 - 95) + 0.00778 \times 1092 - 0.0035 \times 1102.9]$$

$$- 1.147 \times 36.08$$

$$= \mathbf{-\ 406.8\ Btu/h}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.181E

A commercial laundry runs a dryer that has an exit flow of 1 lbm/s moist air at 120 F, 70% relative humidity. To save on the heating cost a counterflow stack heat exchanger is used to heat a cold water line at 50 F for the washers with the exit flow, as shown in Fig. P11.105. Assume the outgoing flow can be cooled to 70 F. Is there a missing flow in the figure? Find the rate of energy recovered by this heat exchanger and the amount of cold water that can be heated to 85 F.

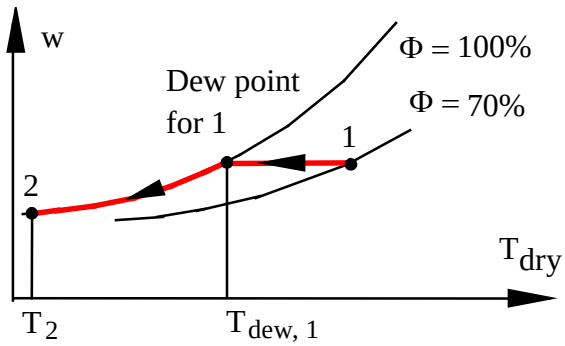
Dryer oulet, 1: 120 F, $\Phi = 70\%$

$\Rightarrow h_{g1} = 1113.54$ Btu/lbm

$P_{g1} = 1.695$ psia,

$P_{v1} = 0.7 \times 1.695$ psia $= 1.1865$ psia

$$\omega_1 = \frac{0.622 \times 1.1865}{14.7 - 1.1865} = 0.0546$$



State 2: $T_2 < T_{dew\,1} \approx 107$ F so $\Phi_2 = 100\%$. $P_{g2} = 0.363$ psia, $h_{g2} = 1092.04$ Btu/lbm

$$h_{f2} = 38.09 \text{ Btu/lbm}, \quad \omega_2 = 0.622 \times 0.363/(14.7 - 0.363) = 0.01575$$

Continuity Eq. water 1-2 line: $\dot{m}_a \omega_1 = \dot{m}_a \omega_2 + \dot{m}_{liq}$; $\dot{m}_{liq} = \dot{m}_a(\omega_1 - \omega_2)$

The mass flow rate of dry air is

$$\dot{m}_a = \dot{m}_{moist\ air}/(1 + \omega_1) = 1 \text{ lbm/s}/(1 + 0.0546) = 0.948 \text{ lbm/s}$$

The heat out of the exhaust air which also equals the energy recovered becomes

$$\dot{Q}_{CV} = \dot{m}_a [\, C_{p\,a}(T_1 - T_2) + \omega_1 h_{g1} - (\omega_1 - \omega_2) h_{f2} - \omega_2 h_{g2} \,]$$

$$= 0.948\, [0.24(120 - 70) + 0.0546 \times 1113.54 - 0.03885 \times 38.09$$

$$- \quad 0.01575 \times 1092.04]$$

$$= 0.948 \text{ lbm/s} \times 54.12 \text{ Btu/lbm} = \mathbf{51.3\ Btu/s}$$

$$\dot{m}_{liq} = \dot{Q}_{CV} / (\, C_{P\,liq}\, \Delta T_{liq}) = 51.3 / [1.0\ (85 - 50)] = \mathbf{1.466\ lbm/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.182E

An indoor pool evaporates 3 lbm/h of water, which is removed by a dehumidifier to maintain 70 F, Φ = 70% in the room. The dehumidifier is a refrigeration cycle in which air flowing over the evaporator cools such that liquid water drops out, and the air continues flowing over the condenser, as shown in Fig. P11.107. For an air flow rate of 0.2 lbm/s the unit requires 1.2 Btu/s input to a motor driving a fan and the compressor and it has a coefficient of performance, $\beta = Q_L / W_C = 2.0$. Find the state of the air after the evaporator, T_2, ω_2, Φ_2 and the heat rejected. Find the state of the air as it returns to the room and the compressor work input.

The unit must remove 3 lbm/h liquid to keep steady state in the room. As water condenses out state 2 is saturated.

1: 70 F, 70% => $P_{g1} = 0.363$ psia, $h_{g1} = 1092.0$ Btu/lbm,

$$P_{v1} = \phi_1 P_{g1} = 0.2541 \text{ psia}, \quad w_1 = 0.622\, P_{v1}/(P_{tot}-P_{v1}) = 0.01094$$

CV 1 to 2: $\dot{m}_{liq} = \dot{m}_a(w_1 - w_2)$ => $w_2 = w_1 - \dot{m}_{liq}/\dot{m}_a$

$$q_L = h_1 - h_2 - (w_1 - w_2)\, h_{f2}$$

$$w_2 = 0.01094 - 3/(3600 \times 0.2) = \mathbf{0.006774}$$

$$P_{v2} = P_{g2} = P_{tot}\, w_2 /(0.622 + w_2) = \frac{14.7 \times 0.006774}{0.628774} = 0.1584 \text{ psia}$$

Table F.7.1: $T_2 =$ **46.8 F** $h_{f2} = 14.88$ btu/lbm, $h_{g2} = 1081.905$ Btu/lbm

$$q_L = 0.24(70 - 46.8) + 0.01094 \times 1092 - 0.006774 \times 1081.905$$
$$- 0.00417 \times 14.88 = 10.12 \text{ Btu/lbm dry air}$$

$$\dot{W}_c = \dot{m}_a\, q_L / \beta = \mathbf{1\ Btu/s}$$

CV Total system :

$$\tilde{h}_3 - \tilde{h}_1 = \dot{W}_{el}/\dot{m}_a - (w_1 - w_2)\, h_f = 1.2/0.2 - 0.062 = 5.938 \text{ Btu/lbm dry air}$$
$$= C_{p\,a}(T_3 - T_1) + w_2 h_{v3} - w_1 h_{v1}$$

Trial and error on T_3

3: $w_3 = w_2$, h_3 => $T_3 =$ **112 F,** $P_{g3} = 1.36$ psia, $P_{v3} = P_{v2} = 0.1584$

$\phi_3 = P_{v3}/P_{g3} = 0.12$ or $\phi_3 =$ **12%**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.183E

To refresh air in a room, a counterflow heat exchanger is mounted in the wall, as shown in Fig. P11.122. It draws in outside air at 33 F, 80% relative humidity and draws room air, 104 F, 50% relative humidity, out. Assume an exchange of 6 lbm/min dry air in a steady flow device, and also that the room air exits the heat exchanger to the atmosphere at 72 F. Find the net amount of water removed from room, any liquid flow in the heat exchanger and (T, ϕ) for the fresh air entering the room.

State 3: $P_{g3} = 1.0804$ psia, $h_{g3} = 1106.73$ Btu/lbm,

$P_{v3} = \phi_3 P_{g3} = 0.5402$, $w_3 = 0.622\, P_{v3}/(P_{tot}-P_{v3}) = 0.02373$

The room air is cooled to 72 F $< T_{dew1} = 82$ F so liquid will form in the exit flow channel and state 4 is saturated.

4: 72 F, $\phi = 100\%$ => $P_{g4} = 0.3918$ psia, $h_{g4} = 1092.91$ Btu/lbm,

$w_4 = 0.017$, $h_{f4} = 40.09$ Btu/lbm

1: 33 F, $\phi = 80\%$ => $P_{g1} = 0.0925$ psia, $h_{g1} = 1075.83$ Btu/lbm,

$P_{v1} = \phi_1 P_{g1} = 0.074$ psia, $w_1 = 0.00315$

CV 3 to 4: $\dot{m}_{liq,4} = \dot{m}_a (w_3 - w_4) = 6\,(0.02373 - 0.017) =$ **0.04 lbm/min**

CV room: $\dot{m}_{v,out} = \dot{m}_a (w_3 - w_2) = \dot{m}_a (w_3 - w_1)$

$= 6(0.02373 - 0.00315) =$ **0.1235 lbm/min**

CV Heat exchanger: $\dot{m}_a(\tilde{h}_2 - \tilde{h}_1) = \dot{m}_a(\tilde{h}_3 - \tilde{h}_4) - \dot{m}_{liq} h_{f4}$

$C_{p\,a}(T_2 - T_1) + w_2 h_{v2} - w_1 h_{v1} = C_{p\,a}(T_3 - T_4) + w_3 h_{v3} - w_4 h_{v4} - (w_3 - w_4)\, h_{f4}$

$0.24(T_2 - 33) + w_2 h_{v2} - 3.3888 = 0.24(104-72) + 26.2627 - 18.5795 - 0.2698$

$0.24\, T_2 + 0.00315\, h_{v2} = 26.402$ btu/lbm

Trial and error on T_2: $T_2 =$ **95.5 F**, $P_{g2} = 0.837$ psia, $P_{v2} = P_{v1}$

$\phi = P_{v2} / P_{g2} = 0.074 / 0.837 = 0.088$ or $\phi =$ **9%**

11.184E

Weighing of masses gives a mixture at 80 F, 35 lbf/in.^{2} with 1 lbm O_2, 3 lbm N_2 and 1 lbm CH_4. Find the partial pressures of each component, the mixture specific volume (mass basis), mixture molecular weight and the total volume.

From Eq. 11.4: $y_i = (m_i / M_i) / \sum m_j/M_j$

$n_{tot} = \sum m_j/M_j = (1/31.999) + (3/28.013) + (1/16.04)$

$= 0.031251 + 0.107093 + 0.062344 = 0.200688$

$y_{O2} = 0.031251/0.200688 = 0.1557, \quad y_{N2} = 0.107093/0.200688 = 0.5336,$

$y_{CH4} = 0.062344/0.200688 = 0.3107$

From Eq.11.10:

$P_{O2} = y_{O2} P_{tot} = 0.1557 \times 35 =$ **5.45 lbf/in.^{2}**,

$P_{N2} = y_{N2} P_{tot} = 0.5336 \times 35 =$ **18.676 lbf/in.^{2}**,

$P_{CH4} = y_{CH4} P_{tot} = 0.3107 \times 35 =$ **10.875 lbf/in.^{2}**

$V_{tot} = n_{tot} \bar{R}T/P = 0.200688 \times 1545 \times 539.7 / (35 \times 144) =$ **33.2 ft^3**

$v = V_{tot}/m_{tot} = 33.2 / (1 + 3 + 1) =$ **6.64 ft^3/lbm**

From Eq.11.5:

$M_{mix} = \sum y_j M_j = m_{tot}/n_{tot} = 5/0.200688 =$ **24.914 lbm/lbmol**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.185E

A mixture of 50% carbon dioxide and 50% water by mass is brought from 2800 R, 150 lbf/in.^{2} to 900 R, 30 lbf/in.^{2} in a polytropic process through a steady flow device. Find the necessary heat transfer and work involved using values from F.4.

Process Pv^n = constant leading to

$$n \ln(v_2/v_1) = \ln(P_1/P_2); \quad v = RT/P$$

$$n = \ln(150/30) / \ln(900 \times 150/30 \times 2800) = 3.3922$$

$$R_{mix} = \Sigma c_i R_i = (0.5 \times 35.1 + 0.5 \times 85.76)/778 = 0.07767 \text{ Btu/lbm R}$$

$$C_{P\,mix} = \Sigma c_i C_{Pi} = 0.5 \times 0.203 + 0.5 \times 0.445 = 0.324 \text{ Btu/lbm R}$$

Work is from Eq.7.18:

$$w = -\int v dP = -\frac{n}{n-1}(P_e v_e - P_i v_i) = -\frac{nR}{n-1}(T_e - T_i)$$

$$= -\frac{3.3922 \times 0.07767}{2.3922}(900 - 2800) = \mathbf{209.3}\ \frac{\mathbf{Btu}}{\mathbf{lbm}}$$

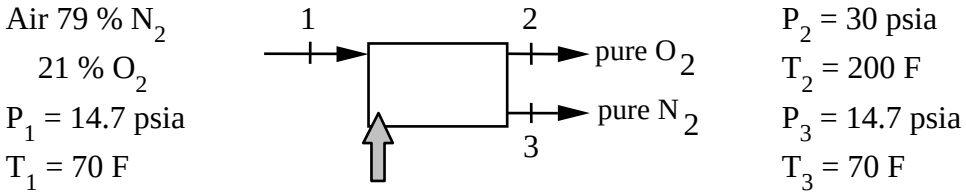
Heat transfer from the energy equation

$$q = h_e - h_i + w = C_P(T_e - T_i) + w = \mathbf{-406.3\ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.186E

A large air separation plant takes in ambient air (79% N_2, 21% O_2 by volume) at 14.7 lbf/in.^{2}, 70 F, at a rate of 2 lb mol/s. It discharges a stream of pure O_2 gas at 30 lbf/in.^{2}, 200 F, and a stream of pure N_2 gas at 14.7 lbf/in.^{2}, 70 F. The plant operates on an electrical power input of 2000 kW. Calculate the net rate of entropy change for the process.



$\dot{n}_1 = 2$ lbmol/s $\qquad -\dot{W}_{IN} = 2000$ kW

$$\dot{S}_{gen} = -\frac{\dot{Q}_{CV}}{T_0} + \sum_i \dot{n}_i \Delta \bar{s}_i = -\frac{\dot{Q}_{CV}}{T_0} + (\dot{n}_2 \bar{s}_2 + \dot{n}_3 \bar{s}_3 - \dot{n}_1 \bar{s}_1)$$

The energy equation, Eq.4.10 gives the heat transfer rate as

$$\dot{Q}_{CV} = \Sigma \dot{n} \Delta \bar{h}_i + \dot{W}_{CV} = \dot{n}_{O_2} \bar{C}_{P0\,O_2} (T_2 - T_1) + \dot{n}_{N_2} \bar{C}_{P0\,N_2} (T_3 - T_1) + \dot{W}_{CV}$$

$$= 0.21 \times 2 \times [32 \times 0.213 \times (200 - 70)] + 0 - 2000 \times 3412/3600$$

$$= +382.6 - 1895.6 = -1513 \text{ Btu/s}$$

Use Eq.6.16 (see page 295 also) for the entropy change

$$\Sigma \dot{n}_i \Delta \bar{s}_i = 0.21 \times 2 \left[32 \times 0.219 \ln \frac{660}{530} - \frac{1545}{778} \ln \frac{30}{0.21 \times 14.7} \right]$$

$$+ 0.79 \times 2 \left[0 - \frac{1545}{778} \ln \frac{14.7}{0.79 \times 14.7} \right]$$

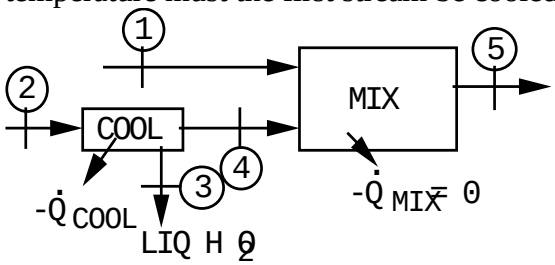
$$= -1.9906 \text{ Btu/R s}$$

$$\dot{S}_{gen} = + \frac{1513}{530} - 1.9906 = \mathbf{0.864\ Btu/R\ s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

11.187E

Ambient air is at a condition of 14.7 lbf/in.^{2}, 95 F, 50% relative humidity. A steady stream of air at 14.7 lbf/in.^{2}, 73 F, 70% relative humidity, is to be produced by first cooling one stream to an appropriate temperature to condense out the proper amount of water and then mix this stream adiabatically with the second one at ambient conditions. What is the ratio of the two flow rates? To what temperature must the first stream be cooled?



$P_1 = P_2 = P_5 = 14.7$ lbf/in^2

$T_1 = T_2 = 95$ F

$\phi_1 = \phi_2 = 0.50$, $\phi_4 = 1.0$

$T_5 = 73$ F, $\phi_5 = 0.70$

$$P_{v1} = P_{v2} = 0.5 \times 0.8246 = 0.4123, \quad w_1 = w_2 = 0.622 \times \frac{0.4123}{14.7 - 0.4123} = 0.0179$$

$$P_{v5} = 0.7 \times 0.4064 = 0.2845 \quad \Rightarrow \quad w_5 = 0.622 \times \frac{0.2845}{14.7 - 0.2845} = 0.0123$$

MIX: Call the mass flow ratio $r = m_{a2}/m_{a1}$

Conservation of water mass: $w_1 + r\, w_4 = (1 + r) w_5$

Energy Eq.: $h_{a1} + w_1 h_{v1} + r h_{a4} + r w_4 h_{v4} = (1 + r) h_{a5} + (1 + r) w_5 h_{v5}$

$$\rightarrow \quad 0.0179 + r w_4 = (1 + r)\, 0.0123$$

or $$r = \frac{0.0179 - 0.0123}{0.0123 - w_4}, \text{ with } \quad w_4 = 0.622 \times \frac{P_{G4}}{14.7 - P_{G4}}$$

$$0.24 \times 555 + 0.0179 \times 1107.2 + r \times 0.24 \times T_4 + r w_4 h_{v4}$$

$$= (1 + r) \times 0.24 \times 533 + (1 + r) \times 0.0123 \times 1093.3$$

or $$r\left[0.24 \times T_4 + w_4 h_{G4} - 141.4\right] + 11.66 = 0$$

Assume $T_4 = 40$ F $\rightarrow P_{G4} = 0.121\,66$ psia, $h_{G4} = 1078.9$ Btu/lbm

$$w_4 = 0.622 \times \frac{0.121\,66}{14.7 - 0.121\,66} = 0.0052$$

$$\frac{m_{a2}}{m_{a1}} = \frac{0.0179 - 0.0123}{0.0123 - 0.0052} = \mathbf{0.7887}$$

$0.7887[0.24 \times 500 + 0.0052 \times 1078.9 - 141.4] + 11.66 = -0.29 \approx 0$ OK

$\Rightarrow \quad T_4 = \mathbf{40\ F}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

The following table gives the values for the compressibility, enthalpy departure and the entropy departure along the saturated liquid-vapor boundary. These are used for all the problems using generalized charts as the figures are very difficult to read accurately (consistently) along the saturated liquid line. It is suggested that the instructor hands out copies of this page or let the students use the computer for homework solutions.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

In-Text Concept Questions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.a

Mention two uses of the Clapeyron equation.

If you have experimental information about saturation properties down to a certain temperature Clapeyron equation will allow you to make an intelligent curve extrapolation of the saturated pressure versus temperature function $P_{sat}(T)$ for lower temperatures.

From Clapeyrons equation we can calculate a heat of evaporation, heat of sublimation or heat of fusion based on measurable properties P, T and v. The similar changes in entropy are also obtained since

$$h_{fg} = Ts_{fg}; \qquad h_{if} = Ts_{if}; \qquad h_{ig} = Ts_{ig}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.b

If I raise the temperature in a constant pressure process, does *g* go up or down?

From the definition and variation in Gibbs function, see Eq.12.15 and Maxwells relation Eq.12.21 last one, we get

$$dg = -s\, dT$$

so Gibbs function decreases as temperature increases.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.c

If I raise the pressure in an isentropic process, does *h* go up or down? Is that independent upon the phase?

Tds = 0 = dh – vdP , so h increases as P increases, for any phase. The magnitude is proportional to v (i.e. large for vapor and small for liquid and solid phases)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.d

If I raise the pressure in a solid at constant *T*, does *s* go up or down?

In Example 12.4, it is found that change in s with P at constant T is negatively related to volume expansivity (a positive value for a solid),

$$ds_T = - v \alpha_P dP_T$$

so raising P decreases s.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.e

What does it imply if the compressibility factor is larger than 1?

A compressibility factor that is greater than one comes from domination of intermolecular forces of repulsion (short range) over forces of attraction (long range) – either high temperature or very high density. This implies that the density is lower than what is predicted by the ideal gas law, the ideal gas law assumes the molecules (atoms) can be pressed closer together.

12.f

What is the benefit of the generalized charts? Which properties must be known besides the charts themselves?

The generalized charts allow for the approximate calculations of enthalpy and entropy changes (and P,v,T behavior), for processes in cases where specific data or equation of state are not known. They also allow for approximate phase boundary determinations.

It is necessary to know the critical pressure and temperature, as well as ideal-gas specific heat.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Concept-Study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.1

The slope dP/dT of the vaporization line is finite as you approach the critical point, yet h_{fg} and v_{fg} both approach zero. How can that be?

The slope is $\left(\frac{dP}{dT}\right)_{sat} = \frac{h_{fg}}{Tv_{fg}}$

Recall the math problem what is the limit of f(x)/g(x) when x goes towards a point where both functions f and g goes towards zero. A finite limit for the ratio is obtained if both first derivatives are different from zero so we have

$$dP/dT \rightarrow [dh_{fg}/dT] \,/\, d(Tv_{fg})/dT \quad \text{as} \quad T \rightarrow T_c$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.2

In view of Clapeyron's equation and Fig. 2.4, is there something special about ice I versus the other forms of ice?

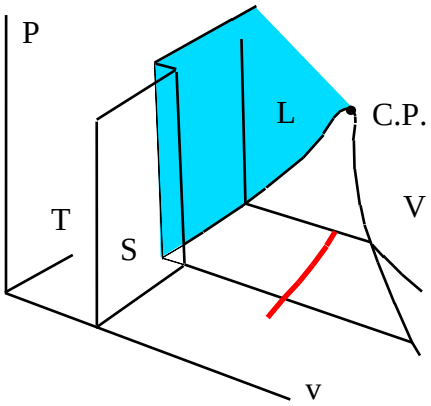
Yes. The slope of the phase boundary dP/dT is negative for ice I to liquid whereas it is positive for all the other ice to liquid interphases. This also means that these other forms of ice are all heavier than liquid water. The pressure must be more than 200 MPa ≈ 2000 atm so even the deepest ocean cannot reach that pressure (recall about 1 atm per 10 meters down).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.3

If we take a derivative as $(\partial P/\partial T)_v$ in the two-phase region, see Figs. 2.7 and 2.8, does it matter what v is? How about T?

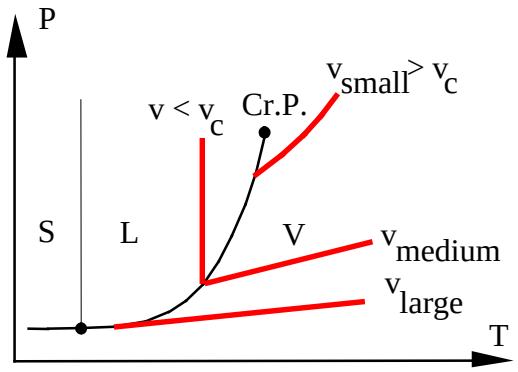
In the two-phase region, P is a function only of T, and not dependent on v. The slope is the same at a given T regardless of v. The slope becomes higher with higher T and generally is the highest near the critical point.

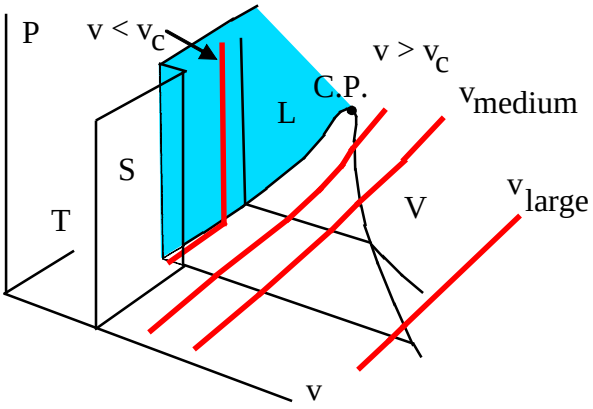


Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.4

Sketch on a P-T diagram how a constant v line behaves in the compressed liquid region, the two-phase L-V region and the superheated vapor region?





The figures are for water where liquid is denser than solid.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.5

If I raise the pressure in an isothermal process does h go up or down for a liquid or solid? What do you need to know if it is a gas phase?

Eq. 12.25: $\left(\frac{\partial h}{\partial P}\right)_T = v - T\left(\frac{\partial v}{\partial T}\right)_P = v[1 - T\alpha_p]$

Liquid or solid, α_p is very small, h increases with P ;

For a gas, we need to know the equation of state.

12.6

The equation of state in Example 12.3 was used as explicit in v. Is it explicit in P?

Yes, the equation can be written explicitly in P.

$$P = \frac{RT}{v + \frac{C}{T^3}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.7

Over what range of states are the various coefficients in Section 12.5 most useful?

For solids or liquids, where the coefficients are essentially constant over a wide range of P's and T's.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.8

For a liquid or a solid is v more sensitive to T or P? How about an ideal gas?

For a liquid or solid, v is much more sensitive to T than P.
For an ideal gas, $v = RT/P$, varies directly with T, inversely with P.

12.9

Most equations of state are developed to cover which range of states?

Most equations of state are developed to cover the gaseous phase, from low to moderate densities. Many cover high-density regions as well, including the compressed liquid region. To cover a wider region the EOS must be more complex and usually has many terms so it is only useful on a computer.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.10

Is an equation of state valid in the two-phase regions?

No. In a two-phase region, P depends only on T. There is a discontinuity at each phase boundary. It is actually difficult to determine the phase boundary from the EOS.

12.11

As $P \to 0$, the specific volume $v \to \infty$. For $P \to \infty$, does $v \to 0$?

At very low P, the substance will be essentially an ideal gas, $Pv = RT$, so that v becomes very large. However at very high P, the substance eventually must become a solid, which cannot be compressed to a volume approaching zero.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.12

Must an equation of state satisfy the two conditions in Eqs. 12.49 and 12.50?

It has been observed from experimental measurements that substances do behave in that manner. If an equation of state is to be accurate in the near-critical region, it would have to satisfy these two conditions.

If the equation is simple it may be overly restrictive to impose these as it may lead to larger inaccuracies in other regions.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.13

At which states are the departure terms for h and s small? What is Z there?

Departure terms for h and s are small at very low pressure or at very high temperature. In both cases, Z is close to 1 and this is the ideal gas region.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.14

The departure functions for h and s as defined are always positive. What does that imply for the real substance h and s values relative to ideal gas values?

Real-substance h and s are less than the corresponding ideal-gas values. This is true for the range shown in the figures, $P_r < 10$. For higher P the isotherms do bend down and negative values are possible.

Generally this means that there are slightly attractive forces between the molecules leading to some binding energy that shows up as a negative potential energy (thus smaller h and u) and it also give a little less chaos (smaller s) due to the stronger binding as compared to ideal gas. When the pressure becomes large the molecules are so close together that the attractive forces turns into repulsive forces and the departure terms are negative.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.15

What is the benefit of Kay's rule versus a mixture equation of state?

Kay's rule for a mixture is not nearly as accurate as an equation of state for the mixture, but it is very simple to use and it is general. For common mixtures new mixture EOS are becoming available in which case they are preferable for a greater accuracy in the calculation.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Clapeyron Equation

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.16

An approximation for the saturation pressure can be $\ln P_{sat} = A - B/T$, where A and B are constants. Which phase transition is that suitable for, and what kind of property variations are assumed?

Clapeyron Equation expressed for the three phase transitions are shown in Eqs. 12.5-12.7. The last two leads to a natural log function if integrated and ideal gas for the vapor is assumed.

$$\frac{dP_{sat}}{dT} = P_{sat} \frac{h_{evap}}{RT^2}$$

where h_{evap} is either h_{fg} or h_{ig}. Separate the variables and integrate

$$P_{sat}^{-1}\, dP_{sat} = h_{evap}\, R^{-1}\, T^{-2}\, dT$$

$$\ln P_{sat} = A - B/T \; ; \qquad B = h_{evap}\, R^{-1}$$

if we also assume h_{evap} is constant and A is an integration constant. The function then applies to the liquid-vapor and the solid-vapor interphases with different values of A and B. As h_{evap} is not excactly constant over a wide interval in T it means that the equation cannot be used for the total domain.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.17

Verify that Clapeyron's equation is satisfied for R-410A at 10°C in Table B.4.

Clapeyron Eq.: $$\frac{dP_{sat}}{dT} = \frac{dP_g}{dT} = \frac{h_{fg}}{Tv_{fg}}$$

B.4: $P = 1085.7$ kPa, $h_{fg} = 208.57$ kJ/kg, $v_{fg} = 0.02295$ m^3/kg

Slope around 10°C best approximated by cord from 5°C to 15°C

$$\frac{dP_g}{dT} = \frac{1255.4 - 933.9}{15 - 5} = 32.15 \text{ kPa/K},$$

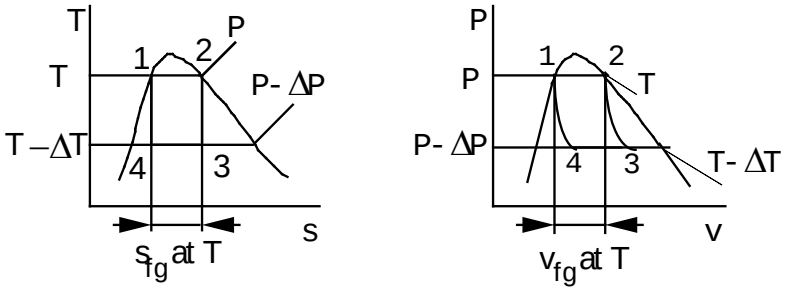
$$\frac{h_{fg}}{Tv_{fg}} = \frac{208.57}{283.15 \times 0.02295} = 32.096 \text{ kPa/K}$$

This fits very well. Use CATT3 to do from 9 to 11°C for better approximation as the saturated pressure is very non-linear in T.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.18

In a Carnot heat engine, the heat addition changes the working fluid from saturated liquid to saturated vapor at T, P. The heat rejection process occurs at lower temperature and pressure ($T - \Delta T$), ($P - \Delta P$). The cycle takes place in a piston cylinder arrangement where the work is boundary work. Apply both the first and second law with simple approximations for the integral equal to work. Then show that the relation between ΔP and ΔT results in the Clapeyron equation in the limit $\Delta T \to dT$.



$$q_H = Ts_{fg}; \quad q_L = (T-\Delta T)s_{fg} \; ; \qquad w_{net} = q_H - q_L = \Delta T s_{fg}$$

The boundary movement work, $w = \int P dv$

$$w_{NET} = P(v_2 - v_1) + \int_2^3 P dv + (P - \Delta P)(v_4 - v_3) + \int_1^4 P dv$$

Approximating,

$$\int_2^3 P dv \approx \left(P - \frac{\Delta P}{2}\right)(v_3 - v_2); \qquad \int_1^4 P dv \approx \left(P - \frac{\Delta P}{2}\right)(v_1 - v_4)$$

Collecting terms: $w_{NET} \approx \Delta P\left[\left(\frac{v_2+v_3}{2}\right) - \left(\frac{v_1+v_4}{2}\right)\right]$

(the smaller the ΔP, the better the approximation)

$$\Rightarrow \frac{\Delta P}{\Delta T} \approx \frac{s_{fg}}{\frac{1}{2}(v_2 + v_3) - \frac{1}{2}(v_1 + v_4)}$$

In the limit as $\Delta T \to 0$: $v_3 \to v_2 = v_g$, $v_4 \to v_1 = v_f$

$$\& \lim_{\Delta T \to 0} \frac{\Delta P}{\Delta T} = \frac{dP_{sat}}{dT} = \frac{s_{fg}}{v_{fg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.19

Verify that Clapeyrons equation is satisfied for carbon dioxide at 6°C in Table B.3.

Clapeyron Eq.: $$\frac{dP_{sat}}{dT} = \frac{dP_g}{dT} = \frac{h_{fg}}{Tv_{fg}}$$

B.3: $P = 4072.0$ kPa, $h_{fg} = 211.59$ kJ/kg, $v_{fg} = 0.00732$ m^3/kg

Slope around 6°C best approximated by cord from 4°C to 8°C

$$\frac{dP_g}{dT} = \frac{4283.1 - 3868.8}{8 - 4} = 103.575 \text{ kPa/K},$$

$$\frac{h_{fg}}{Tv_{fg}} = \frac{211.59}{279.15 \times 0.00732} \frac{\text{kJ/kg}}{\text{K m}^3\text{/kg}} = 103.549 \text{ kPa/K}$$

This fits very well.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.20

Use the approximation given in problem 12.16 and Table B.1 to determine A and B for steam from properties at 25°C only. Use the equation to predict the saturation pressure at 30°C and compare to table value.

$$\ln P_{sat} = A - B/T \qquad \Rightarrow \qquad \frac{dP_{sat}}{dT} = P_{sat}\,(-B)(-T^{-2})$$

so we notice from Eq.12.7 and Table values from B.1.1 and A.5 that

$$B = \frac{h_{fg}}{R} = \frac{2442.3}{0.4615}\frac{\text{kJ/kg}}{\text{kJ/kg-K}} = 5292 \text{ K}$$

Now the constant A comes from the saturation pressure as

$$A = \ln P_{sat} + B/T = \ln 3.169 + \frac{5292}{273.15 + 25} = 18.9032$$

Use the equation to predict the saturation pressure at 30°C as

$$\ln P_{sat} = A - B/T = 18.9032 - \frac{5292}{273.15 + 30} = 1.4462$$

$$P_{sat} = 4.2469 \text{ kPa}$$

compare this with the table value of $P_{sat} = 4.246$ kPa and we have a very accurate approximation.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.21

A certain refrigerant vapor enters a steady flow constant pressure condenser at 150 kPa, 70°C, at a rate of 1.5 kg/s, and it exits as saturated liquid. Calculate the rate of heat transfer from the condenser. It may be assumed that the vapor is an ideal gas, and also that at saturation, $v_f << v_g$. The following quantities are known for this refrigerant:

$$\ln P_g = 8.15 - 1000/T\ ; \qquad C_P = 0.7\ \text{kJ/kg K}$$

with pressure in kPa and temperature in K. The molecular mass is 100.

Solution:

Refrigerant: State 1 $T_1 = 70^oC$ $P_1 = 150$ kPa

State 2 $P_2 = 150$ kPa $x_2 = 1.0$ State 3 $P_3 = 150$ kPa $x_3 = 0.0$

Energy Eq.: $_1q_3 = h_3 - h_1 = (h_3 - h_2) + (h_2 - h_1) = - h_{fg\ T3} + C_{p0}(T_2 - T_1)$

Get the saturation temperature at the given pressure

$$\ln (150) = 8.15 - 1000/T_2 \ \Rightarrow\ T_2 = 318.5\ \text{K} = 45.3^oC = T_3$$

Now get the enthalpy of evaporation $h_{fg\ T3}$

$$\frac{dP_g}{dT} = \frac{h_{fg}}{Tv_{fg}}, \qquad v_{fg} \approx v_g = \frac{RT}{P_g}, \qquad \frac{dP_g}{dT} = P_g \frac{d \ln P_g}{dT} = \frac{h_{fg}}{RT^2} P_g$$

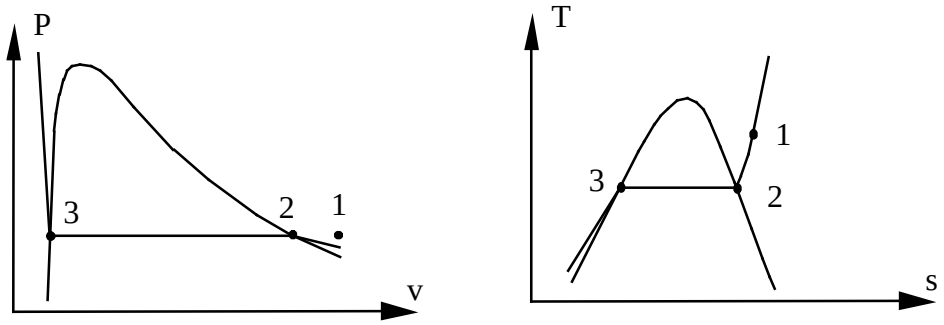
$$\frac{d \ln P_g}{dT} = +1000/T^2 = h_{fg}/RT^2$$

$$h_{fg} = 1000 \times R = 1000 \times 8.3145/100 = 83.15\ \text{kJ/kg}$$

Substitute into the energy equation

$$_1q_3 = -83.15 + 0.7(45.3 - 70) = -100.44\ \text{kJ/kg}$$

$$\dot{Q}_{COND} = 1.5(-100.44) = \mathbf{-150.6\ kW}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.22

Calculate the values h_{fg} and s_{fg} for nitrogen at 70 K and at 110 K from the Clapeyron equation, using the necessary pressure and specific volume values from Table B.6.1.

Clapeyron equation Eq.12.7: $$\frac{dP_g}{dT} = \frac{h_{fg}}{Tv_{fg}} = \frac{s_{fg}}{v_{fg}}$$

For N_2 at 70 K, using values for P_g from Table B.6 at 75 K and 65 K, and also v_{fg} at 70 K,

$$h_{fg} \approx T(v_g - v_f)\frac{\Delta P_g}{\Delta T} = 70(0.525\ 015)\left(\frac{76.1-17.41}{75-65}\right) = 215.7 \text{ kJ/kg}$$

$$s_{fg} = h_{fg}/T = 3.081 \text{ kJ/kg K}$$

Table B.6.1: $h_{fg} = 207.8$ kJ/kg and $s_{fg} = 2.97$ kJ/kg K

Comparison not very close because P_g not linear function of T. Using 71 K & 69 K from the software, we can then get

$$h_{fg} = 70(0.525\ 015)\left(\frac{44.56-33.24}{71-69}\right) = 208.0 \text{ kJ/kg}$$

At 110 K,

$$h_{fg} \approx 110(0.014\ 342)\left(\frac{1938.8-1084.2}{115-105}\right) = 134.82 \text{ kJ/kg}$$

$$s_{fg} = h_{fg}/T = \frac{134.82}{110} = 1.226 \text{ kJ/kg K}$$

Table B.6.1: $h_{fg} = 134.17$ kJ/kg and $s_{fg} = 1.22$ kJ/kg K

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.23

Find the saturation pressure for refrigerant R-410A at –80^{o}C assuming it is higher than the triple point temperature.

The lowest temperature in Table B.4 for R-410A is -60^{o}C, so it must be extended to -80^{o}C using the Clapeyron Eq. 12.7 integrated as in example 12.1

Table B.4 at T_1 = -60^{o}C = 213.15 K:

$$P_1 = 64.1 \text{ kPa}, \quad R = 0.1145 \text{ kJ/kg-K}$$

$$\ln \frac{P}{P_1} = \frac{h_{fg}}{R} \frac{(T - T_1)}{T \times T_1} = \frac{279.96}{0.1145} \frac{(193.15 - 213.15)}{193.15 \times 213.15} = -1.1878$$

$$P = 64.1 \exp(-1.1878) = \mathbf{19.54 \text{ kPa}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.24

Ammonia at –70°C is used in a special application at a quality of 50%. Assume the only table available is B.2 that goes down to –50°C. To size a tank to hold 0.5 kg with x = 0.5, give your best estimate for the saturated pressure and the tank volume.

To size the tank we need the volume and thus the specific volume. If we do not have the table values for v_f and v_g we must estimate those at the lower T. We therefore use Clapeyron equation to extrapolate from –50°C to –70°C to get the saturation pressure and thus v_g assuming ideal gas for the vapor.

The values for v_f and h_{fg} do not change significantly so we estimate

Between -50°C and –70°C: $h_{fg} = 1430$ kJ/kg

and at –70°C we get: $v_f = 0.001375$ m^3/kg

The integration of Eq.12.7 is the same as in Example 12.1 so we get

$$\ln \frac{P_2}{P_1} = \frac{h_{fg}}{R} \left(\frac{T_2 - T_1}{T_2 T_1} \right) = \frac{1430}{0.4882} \frac{-70 + 50}{203.15 \times 223.15} = -1.2923$$

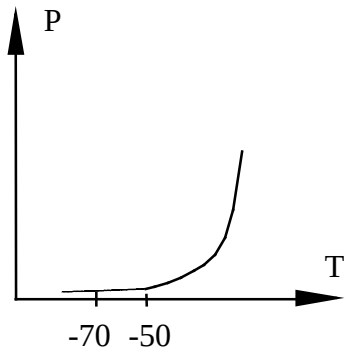
$$P_2 = P_1 \exp(-1.2923) = 40.9 \exp(-1.2923) = 11.2 \text{ kPa}$$

$$v_g = RT_2/P_2 = \frac{0.4882 \times 203.15}{11.2} = 8.855 \text{ m}^3/\text{kg}$$

$$v_2 = (1-x)\, v_f + x\, v_g = 0.5 \times 0.001375 + 0.5 \times 8.855 = 4.428 \text{ m}^3/\text{kg}$$

$$V_2 = mv_2 = \mathbf{2.214\ m^3}$$

A straight line extrapolation will give a negative pressure.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.25

Use the approximation given in problem 12.16 and Table B.4 to determine A and B for refrigerant R-410A from properties at 0^oC only. Use the equation to predict the saturation pressure at 5^oC and compare to table value.

$$\ln P_{sat} = A - B/T \qquad \Rightarrow \qquad \frac{dP_{sat}}{dT} = P_{sat}\,(-B)(-T^{-2})$$

so we notice from Eq.12.7 and Table values from B.4.1 and A.5 that

$$B = \frac{h_{fg}}{R} = \frac{221.37}{0.1145}\ \frac{kJ/kg}{kJ/kg\text{-}K} = 1933.4\ K$$

Now the constant A comes from the saturation pressure as

$$A = \ln P_{sat} + B/T = \ln 798.7 + \frac{1933.4}{273.15} = 13.7611$$

Use the equation to predict the saturation pressure at 5^oC as

$$\ln P_{sat} = A - B/T = 13.7611 - \frac{1933.4}{273.15 + 5} = 6.8102$$

$$P_{sat} = 907\ kPa$$

compare this with the table value of $P_{sat} = 933.9$ kPa and we have an approximation 3% low. Notice h_{fg} decreases so we could have used a lower value for the average in the interval.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.26

The triple point of CO_2 is -56.4^{o}C. Predict the saturation pressure at that point using Table B.3.

The lowest temperature in Table B.3 for CO_2 is -50^{o}C, so it must be extended to -56.4^{o}C = 216.75 K using the Clapeyron Eq. 12.7 integrated as in Ex. 12.1

Table B.3: at T_1 = -50^{o}C = 223.15 K, P_1 = 682.3 kPa, h_{fg} = 339.73 kJ/kg

Table A.5: R = 0.1889 kJ/kg-K

$$\ln \frac{P}{P_1} = \frac{h_{fg}}{R} \frac{(T - T_1)}{T \times T_1} = \frac{339.73}{0.1889} \frac{(216.75 - 223.15)}{216.75 \times 223.15} = -0.23797$$

$$P = 682.3 \exp(-0.23797) = \mathbf{537.8\ kPa}$$

Notice from Table 3.2: P = 520.8 kPa so we are 3% high. As h_{fg} becomes larger for lower T's we could have estimated a more suitable value for the interval from -50 to -56.4^{o}C

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.27

Helium boils at 4.22 K at atmospheric pressure, 101.3 kPa, with h_{fg} = 83.3 kJ/kmol. By pumping a vacuum over liquid helium, the pressure can be lowered, and it may then boil at a lower temperature. Estimate the necessary pressure to produce a boiling temperature of 1 K and one of 0.5 K.

Solution:

Helium at 4.22 K: P_1 = 0.1013 MPa, $\bar{h}_{FG}$ = 83.3 kJ/kmol

$$\frac{dP_{SAT}}{dT} = \frac{h_{FG}}{Tv_{FG}} \approx \frac{h_{FG}P_{SAT}}{RT^2} \quad \Rightarrow \quad \ln\frac{P_2}{P_1} = \frac{h_{FG}}{R}\left[\frac{1}{T_1} - \frac{1}{T_2}\right]$$

For T_2 = 1.0 K:

$$\ln\frac{P_2}{101.3} = \frac{83.3}{8.3145}\left[\frac{1}{4.22} - \frac{1}{1.0}\right] \quad => \quad P_2 = 0.048 \text{ kPa} = \mathbf{48\ Pa}$$

For T_2 = 0.5 K:

$$\ln\frac{P_2}{101.3} = \frac{83.3}{8.3145}\left[\frac{1}{4.22} - \frac{1}{0.5}\right]$$

$$P_2 = 2.1601\times10^{-6} \text{ kPa} = \mathbf{2.1601 \times 10^{-3}\ Pa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.28

Using the properties of water at the triple point, develop an equation for the saturation pressure along the fusion line as a function of temperature.

Solution:

The fusion line is shown in Fig. 2.3 as the S-L interphase. From Eq.12.5 we have

$$\frac{dP_{fusion}}{dT} = \frac{h_{if}}{Tv_{if}}$$

Assume h_{if} and v_{if} are constant over a range of T's. We do not have any simple models for these as function of T other than curve fitting. Then we can integrate the above equation from the triple point (T_1, P_1) to get the pressure P(T) as

$$P - P_1 = \frac{h_{if}}{v_{if}} \ln \frac{T}{T_1}$$

Now take the properties at the triple point from B.1.1 and B.1.5

$$P_1 = 0.6113 \text{ kPa}, \quad T_1 = 273.16 \text{ K}$$

$$v_{if} = v_f - v_i = 0.001 - 0.0010908 = -9.08 \times 10^{-5} \text{ m}^3/\text{kg}$$

$$h_{if} = h_f - h_i = 0.0 - (-333.4) = 333.4 \text{ kJ/kg}$$

The function that approximates the pressure becomes

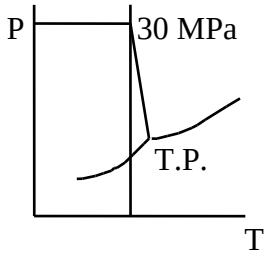
$$P = 0.6113 - 3.672 \times 10^6 \ln \frac{T}{T_1} \quad [\text{kPa}]$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.29

Using thermodynamic data for water from Tables B.1.1 and B.1.5, estimate the freezing temperature of liquid water at a pressure of 30 MPa.

H_2O $\quad \dfrac{dP_{if}}{dT} = \dfrac{h_{if}}{Tv_{if}} \approx \text{const}$



At the triple point,

$$v_{if} = v_f - v_i = 0.001\,000 - 0.001\,090\,8 = -0.000\,090\,8 \text{ m}^3/\text{kg}$$

$$h_{if} = h_f - h_i = 0.01 - (-333.40) = 333.41 \text{ kJ/kg}$$

$$\frac{dP_{if}}{dT} = \frac{333.41}{273.16(-0.000\,090\,8)} = -13\,442 \text{ kPa/K}$$

$\Rightarrow$ at P = 30 MPa,

$$T \approx 0.01 + \frac{(30\,000-0.6)}{(-13\,442)} = \mathbf{-2.2\ ^oC}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.30

Ice (solid water) at –3°C, 100 kPa, is compressed isothermally until it becomes liquid. Find the required pressure.

Water, triple point $T = 0.01^{o}C$, $P = 0.6113$ kPa

Table B.1.1: $v_f = 0.001\ m^3/kg$, $h_f = 0.01$ kJ/kg,

Tabel B.1.5: $v_i = 0.001\ 0908\ m^3/kg$, $h_i = -333.4$ kJ/kg

Clapeyron $$\frac{dP_{if}}{dT} = \frac{h_f - h_i}{(v_f - v_i)T} = \frac{333.4}{-0.0000908 \times 273.16} = -13\ 442\ \text{kPa/K}$$

$$\Delta P \approx \frac{dP_{if}}{dT}\Delta T = -13\ 442(-3 - 0.01) = 40\ 460\ \text{kPa}$$

$$P = P_{tp} + \Delta P = \mathbf{40\ 461\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.31

From the phase diagram for carbon dioxide in Fig. 2.5 and 2.4 for water what can you infer for the specific volume change during melting assuming the liquid has a higher h than the solid phase for those two substances.

The saturated pressure versus temperature has a positive slope for carbon dioxide and a negative slope for water.

$$\text{Clapeyron} \qquad \frac{dP_{if}}{dT} = \frac{h_f - h_i}{(v_f - v_i)T}$$

So if we assume $h_f - h_i > 0$ then we notice that the volume change in the melting gives

Water: $\quad v_f - v_i < 0 \quad$ so $\quad v_f < v_i$

Carbon dioxide: $\quad v_f - v_i > 0 \quad$ so $\quad v_f > v_i$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.32

A container has a double wall where the wall cavity is filled with carbon dioxide at room temperature and pressure. When the container is filled with a cryogenic liquid at 100 K the carbon dioxide will freeze so that the wall cavity has a mixture of solid and vapor carbon dioxide at the sublimation pressure. Assume that we do not have data for CO_2 at 100 K, but it is known that at −90°C: P_{sat} = 38.1 kPa, h_{IG} = 574.5 kJ/kg. Estimate the pressure in the wall cavity at 100 K.

Solution:

For CO_2 space: at T_1 = -90 ^oC = 183.2 K , P_1 = 38.1 kPa, h_{IG} = 574.5 kJ/kg

For $T_2 = T_{CO2}$ = 100 K: Clapeyron $\quad \dfrac{dP_{SUB}}{dT} = \dfrac{h_{IG}}{Tv_{IG}} \approx \dfrac{h_{IG}P_{SUB}}{RT^2}$

$$\ln\frac{P_2}{P_1} = \frac{h_{IG}}{R}\left[\frac{1}{183.2} - \frac{1}{100}\right] = \frac{574.5}{0.188\ 92}\left[\frac{1}{183.2} - \frac{1}{100}\right] = -13.81$$

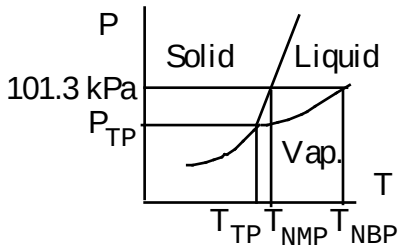
or $\quad P_2 = P_1 \times 1.005\times10^{-6} \quad \Rightarrow \quad P_2 = 3.83\times10^{-5}$ kPa = $\mathbf{3.83\times10^{-2}\ Pa}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.33

Small solid particles formed in combustion should be investigated. We would like to know the sublimation pressure as a function of temperature. The only information available is *T*, h_{FG} for boiling at 101.3 kPa and *T*, h_{IF} for melting at 101.3 kPa. Develop a procedure that will allow a determination of the sublimation pressure, $P_{sat}(T)$.

T_{NBP} = normal boiling pt T.
T_{NMP} = normal melting pt T.
T_{TP} = triple point T.



1) $T_{TP} \approx T_{NMP}$

2) $$\int_{0.1013\ MPa}^{P_{TP}} (1/P_{SAT})\, dP_{SAT} \approx \int_{T_{NMP}}^{T_{TP}} \frac{h_{FG}}{RT^2}\, dT$$

Since $h_{FG} \approx$ const $\approx h_{FG\ NBP}$ the integral over temperature becomes

$$\ln \frac{P_{TP}}{0.1013} \approx \frac{h_{FG\ NBP}}{R}\left[\frac{1}{T_{NBP}} - \frac{1}{T_{TP}}\right] \quad \rightarrow \quad \text{get } P_{TP}$$

3) $h_{IG\ at\ TP} = h_G - h_I = (h_G - h_F) + (h_F - h_I) \approx h_{FG\ NBP} + h_{IF\ NMP}$

Assume $h_{IG} \approx$ const. again we can evaluate the integral

$$\ln \frac{P_{SUB}}{P_{TP}} = \int_{P_{TP}}^{P_{SUB}} (1/P_{SUB})\, dP_{SUB} \approx \int_{T_{TP}}^{T} \frac{h_{IG}}{RT^2}\, dT \approx \frac{h_{IG}}{R}\left[\frac{1}{T_{TP}} - \frac{1}{T}\right]$$

or $P_{SUB} = fn(T)$

12.34

Use Gibbs relation du = Tds – Pdv and one of Maxwell's relations to find an expression for $(\partial u/\partial P)_T$ that only has properties P, v and T involved. What is the value of that partial derivative if you have an ideal gas?

du = Tds – Pdv divide this by dP so we get

$$\left(\frac{\partial u}{\partial P}\right)_T = T\left(\frac{\partial s}{\partial P}\right)_T - P\left(\frac{\partial v}{\partial P}\right)_T = -T\left(\frac{\partial v}{\partial T}\right)_P - P\left(\frac{\partial v}{\partial P}\right)_T$$

where we have used Maxwell Eq.12.19. Now for an ideal gas we get

Ideal gas: $Pv = RT \quad \Rightarrow \quad v = \frac{RT}{P}$

then the derivatives are

$$\left(\frac{\partial v}{\partial T}\right)_P = \frac{R}{P} \qquad \text{and} \qquad \left(\frac{\partial v}{\partial P}\right)_T = -RTP^{-2}$$

and the derivative of u is

$$\left(\frac{\partial u}{\partial P}\right)_T = -T\left(\frac{\partial v}{\partial T}\right)_P - P\left(\frac{\partial v}{\partial P}\right)_T = -T\frac{R}{P} - P(-RTP^{-2}) = 0$$

This confirms that u is not sensitive to P and only a function of T.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.35

The Joule-Thomson coefficient μ_J is a measure of the direction and magnitude of the temperature change with pressure in a throttling process. For any three properties x,y,z use the mathematical relation

$$\left(\frac{\partial x}{\partial y}\right)_z \left(\frac{\partial y}{\partial z}\right)_x \left(\frac{\partial z}{\partial x}\right)_y = -1$$

to show the following relations for the Joule-Thomson coefficient:

$$\mu_J = \left(\frac{\partial T}{\partial P}\right)_h = \frac{T\left(\frac{\partial v}{\partial T}\right)_P - v}{C_P} = \frac{RT^2}{PC_P}\left(\frac{\partial Z}{\partial T}\right)_P$$

Let x = T, y = P and z = h and substitute into the relations as:

$$\left(\frac{\partial T}{\partial P}\right)_h \left(\frac{\partial P}{\partial h}\right)_T \left(\frac{\partial h}{\partial T}\right)_P = -1$$

Then we have the definition of specific heat as $C_P = \left(\frac{\partial h}{\partial T}\right)_P$ so solve for the first term

$$\mu_J = \left(\frac{\partial T}{\partial P}\right)_h = -\frac{1}{C_P} \Big/ \left(\frac{\partial P}{\partial h}\right)_T = -\frac{1}{C_P}\left(\frac{\partial h}{\partial P}\right)_T$$

The last derivative is substituted with Eq.12.25 so we get

$$\mu_J = \left(\frac{\partial T}{\partial P}\right)_h = \frac{T\left(\frac{\partial v}{\partial T}\right)_P - v}{C_P}$$

If we use the compressibility factor then we get

$$Pv = ZRT \quad \Rightarrow \quad \left(\frac{\partial v}{\partial T}\right)_P = \frac{ZR}{P} + \frac{RT}{P}\left(\frac{\partial Z}{\partial T}\right)_P = \frac{v}{T} + \frac{RT}{P}\left(\frac{\partial Z}{\partial T}\right)_P$$

so then

$$T\left(\frac{\partial v}{\partial T}\right)_P - v = v + \frac{RT^2}{P}\left(\frac{\partial Z}{\partial T}\right)_P - v = \frac{RT^2}{P}\left(\frac{\partial Z}{\partial T}\right)_P$$

and we have shown the last expression also.

$$\mu_J = \left(\frac{\partial T}{\partial P}\right)_h = \frac{T\left(\frac{\partial v}{\partial T}\right)_P - v}{C_P} = \frac{RT^2}{PC_P}\left(\frac{\partial Z}{\partial T}\right)_P$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.36

Find the Joule-Thomson coefficient for an ideal gas from the expression given in Problem 12.35

$$\mu_J = \left(\frac{\partial T}{\partial P}\right)_h = \frac{T\left(\frac{\partial v}{\partial T}\right)_P - v}{C_P} = \frac{RT^2}{PC_P}\left(\frac{\partial Z}{\partial T}\right)_P$$

For an ideal gas: v = RT/P so then the partial derivative

$$\left(\frac{\partial v}{\partial T}\right)_P = \frac{R}{P} \quad \Rightarrow \quad T\left(\frac{\partial v}{\partial T}\right)_P - v = \frac{RT}{P} - v = v - v = 0$$

For an ideal gas Z = 1 so the very last derivative of Z is also zero.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.37

Start from Gibbs relation dh = Tds + vdP and use one of Maxwell's equation to get $(\partial h/\partial v)_T$ in terms of properties P, v and T. Then use Eq.12.24 to also find an expression for $(\partial h/\partial T)_v$.

Find $\left(\frac{\partial h}{\partial v}\right)_T$ and $\left(\frac{\partial h}{\partial T}\right)_v$

dh = Tds + vdP and use Eq.12.18

$$\Rightarrow \quad \left(\frac{\partial h}{\partial v}\right)_T = T\left(\frac{\partial s}{\partial v}\right)_T + v\left(\frac{\partial P}{\partial v}\right)_T = T\left(\frac{\partial P}{\partial T}\right)_v + v\left(\frac{\partial P}{\partial v}\right)_T$$

Also for the second first derivative use Eq.12.24

$$\left(\frac{\partial h}{\partial T}\right)_v = T\left(\frac{\partial s}{\partial T}\right)_v + v\left(\frac{\partial P}{\partial T}\right)_v = C_v + v\left(\frac{\partial P}{\partial T}\right)_v$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.38

From Eqs. 12.23 and 12.24 and the knowledge that $C_p > C_v$ what can you conclude about the slopes of constant v and constant P curves in a T-s diagram? Notice that we are looking at functions T(s, P or v given).

Solution:

The functions and their slopes are:

Constant v: T(s) at that v with slope $\left(\frac{\partial T}{\partial s}\right)_v$

Constant P: T(s) at that P with slope $\left(\frac{\partial T}{\partial s}\right)_P$

Slopes of these functions are now evaluated using Eq.12.23 and Eq.12.24 as

$$\left(\frac{\partial T}{\partial s}\right)_P = \left(\left(\frac{\partial s}{\partial T}\right)_P\right)^{-1} = \frac{T}{C_p}$$

$$\left(\frac{\partial T}{\partial s}\right)_v = \left(\left(\frac{\partial s}{\partial T}\right)_v\right)^{-1} = \frac{T}{C_v}$$

Since we know $C_p > C_v$ then it follows that $T/C_v > T/C_p$ and therefore

$$\left(\frac{\partial T}{\partial s}\right)_v > \left(\frac{\partial T}{\partial s}\right)_P$$

which means that constant v-lines are steeper than constant P lines in a T-s diagram.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.39

Derive expressions for $(\partial T/\partial v)_u$ and for $(\partial h/\partial s)_v$ that do not contain the properties *h, u,* or *s*. Use Eq. 12.30 with du = 0.

$$\left(\frac{\partial T}{\partial v}\right)_u = -\left(\frac{\partial u}{\partial v}\right)_T \Big/ \left(\frac{\partial u}{\partial T}\right)_v = \frac{P - T\left(\frac{\partial P}{\partial T}\right)_v}{C_v} \qquad \text{(see Eqs. 12.33 and 12.34)}$$

$$\text{As } dh = Tds + vdP \Rightarrow \left(\frac{\partial h}{\partial s}\right)_v = T + v\left(\frac{\partial P}{\partial s}\right)_v = T - v\left(\frac{\partial T}{\partial v}\right)_s \quad \text{(Eq.12.20)}$$

$$\text{But} \quad \left(\frac{\partial T}{\partial v}\right)_s = -\left(\frac{\partial s}{\partial v}\right)_T \Big/ \left(\frac{\partial s}{\partial T}\right)_v = -\frac{T\left(\frac{\partial P}{\partial T}\right)_v}{C_v} \qquad \text{(Eq.12.22)}$$

$$\Rightarrow \qquad \left(\frac{\partial h}{\partial s}\right)_v = T + \frac{vT}{C_v}\left(\frac{\partial P}{\partial T}\right)_v$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.40

Evaluate the isothermal changes in the internal energy, the enthalpy and the entropy for an ideal gas. Confirm the results in Chapters 3 and 6.

We need to evaluate du_T, dh_T and ds_T for an ideal gas: $P = RT/v$.

From Eq.12.31 we get

$$du_T = [\ T \left(\frac{\partial P}{\partial T}\right)_v - P\ ]\ dv_T = [\ T\ (\frac{R}{v}) - P\ ]\ dv_T = [\ P - P]\ dv_T = 0$$

From Eq.12.27 we get using $v = RT/P$

$$dh_T = [\ v - T \left(\frac{\partial v}{\partial T}\right)_P\ ]\ dP_T = [\ v - T\ (\frac{R}{P})\ ]\ dP_T = [\ v - v\ ]\ dP_T = 0$$

These two equations confirms the statements in chapter 5 that u and h are functions of T only for an ideal gas.

From Eq.12.32 or Eq.12.34 we get

$$ds_T = -\left(\frac{\partial v}{\partial T}\right)_P dP_T = \left(\frac{\partial P}{\partial T}\right)_v dv_T$$

$$= -\frac{R}{P} dP_T = \frac{R}{v} dv_T$$

so the change in s can be integrated to find

$$s_2 - s_1 = -R \ln \frac{P_2}{P_1} = R \ln \frac{v_2}{v_1} \qquad \text{when } T_2 = T_1$$

12.41

Develop an expression for the variation in temperature with pressure in a constant entropy process, $(\partial T/\partial P)_s$, that only includes the properties P–v–T and the specific heat, C_p. Follow the development for Eq.12.32.

$$\left(\frac{\partial T}{\partial P}\right)_s = -\frac{\left(\frac{\partial s}{\partial P}\right)_T}{\left(\frac{\partial s}{\partial T}\right)_P} = -\frac{-\left(\frac{\partial v}{\partial T}\right)_P}{(C_P/T)} = \frac{T}{C_P}\left(\frac{\partial v}{\partial T}\right)_P$$

$\left\{\left(\frac{\partial s}{\partial P}\right)_T = -\left(\frac{\partial v}{\partial T}\right)_P\right.$, Maxwell relation Eq. 12.23 and the other is Eq.12.27$\}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.42

Use Eq. 12.34 to get an expression for the derivative $(\partial T/\partial v)_s$. What is the general shape of a constant s process curve in a T-v diagram? For an ideal gas can you say a little more about the shape?

Equation 12.34 says

$$ds = C_v \frac{dT}{T} + \left(\frac{\partial P}{\partial T}\right)_v dv$$

so then in a constant s process we have ds = 0 and we find

$$\left(\frac{\partial T}{\partial v}\right)_s = -\frac{T}{C_v}\left(\frac{\partial P}{\partial T}\right)_v$$

As T is higher the slope is steeper (but negative) unless the last term $(\partial P/\partial T)_v$ counteracts. If we have an ideal gas this last term can be determined

$$P = RT/v \qquad \Rightarrow \qquad \left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v}$$

$$\left(\frac{\partial T}{\partial v}\right)_s = -\frac{T}{C_v}\frac{R}{v} = -\frac{P}{C_v}$$

and we see the slope is steeper for higher P and a little lower for higher T as C_v is an increasing function of T.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.43

Show that the P-v-T relation as P(v – b) = RT satisfies the mathematical relation in Problem 12.35.

$$\left(\frac{\partial x}{\partial y}\right)_z \left(\frac{\partial y}{\partial z}\right)_x \left(\frac{\partial z}{\partial x}\right)_y = -1$$

Let (x, y, z) be (P, v, T) so we have

$$\left(\frac{\partial P}{\partial v}\right)_T \left(\frac{\partial v}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_v = -1$$

The first derivative becomes, P = RT/(v – b)

$$\left(\frac{\partial P}{\partial v}\right)_T = -RT\,(v-b)^{-2} = -P/(v-b)$$

The second derivative, v = b + RT/P

$$\left(\frac{\partial v}{\partial T}\right)_P = R/P$$

The third derivative, T = (P/R)(v – b)

$$\left(\frac{\partial T}{\partial P}\right)_v = (v-b)/R$$

Substitute all three derivatives into the relation

$$\left(\frac{\partial P}{\partial v}\right)_T \left(\frac{\partial v}{\partial T}\right)_P \left(\frac{\partial T}{\partial P}\right)_v = -\frac{RT}{(v-b)^2} \times \frac{R}{P} \times \frac{v-b}{R} = -\frac{RT}{(v-b)} \times \frac{1}{P} = -1$$

with the last one recognized as a rewrite of the original EOS.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Volume Expansivity and Compressibility

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.44

What are the volume expansivity α_p, the isothermal compressibility β_T, and the adiabatic compressibility β_s for an ideal gas?

The volume expansivity from Eq.12.37 and ideal gas v = RT/P gives

$$\alpha_p = \frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_P = \frac{1}{v}\left(\frac{R}{P}\right) = \frac{1}{T}$$

The isothermal compressibility from Eq.12.38 and ideal gas gives

$$\beta_T = -\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_T = -\frac{1}{v}\left(-RT\,P^{-2}\right) = \frac{1}{P}$$

The adiabatic compressibility β_s from Eq.12.40 and ideal gas

$$\beta_s = -\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_s$$

From Eq.12.32 we get for constant s (ds = 0)

$$\left(\frac{\partial T}{\partial P}\right)_s = \frac{T}{C_p}\left(\frac{\partial v}{\partial T}\right)_P = \frac{T}{C_p}\frac{R}{P} = \frac{v}{C_p}$$

and from Eq.12.34 we get

$$\left(\frac{\partial v}{\partial T}\right)_s = -\frac{C_v}{T}\left(\frac{\partial P}{\partial T}\right)_v = -\frac{C_v}{T}\frac{v}{R} = -\frac{C_v}{P}$$

Finally we can form the desired derivative

$$\left(\frac{\partial v}{\partial P}\right)_s = \left(\frac{\partial v}{\partial T}\right)_s \left(\frac{\partial T}{\partial P}\right)_s = -\frac{C_v}{P}\frac{v}{C_p} = -\frac{v}{kP}$$

$$\beta_s = -\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_s = \left(-\frac{1}{v}\right)\left(-\frac{v}{kP}\right) = \frac{1}{kP} = \frac{1}{k}\beta_T$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.45

Assume a substance has uniform properties in all directions with $V = L_x L_y L_z$ and show that volume expansivity $\alpha_p = 3\delta_T$. Hint: differentiate with respect to T and divide by V.

$$V = L_x L_y L_z$$

From Eq.12.37

$$\alpha_p = \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P = \frac{1}{L_x L_y L_z}\left(\frac{\partial\, L_x L_y L_z}{\partial T}\right)_P$$

$$= \frac{L_y L_z}{L_x L_y L_z}\left(\frac{\partial\, L_x}{\partial T}\right)_P + \frac{L_x L_z}{L_x L_y L_z}\left(\frac{\partial\, L_y}{\partial T}\right)_P + \frac{L_x L_y}{L_x L_y L_z}\left(\frac{\partial\, L_z}{\partial T}\right)_P$$

$$= \frac{1}{L_x}\left(\frac{\partial\, L_x}{\partial T}\right)_P + \frac{1}{L_y}\left(\frac{\partial\, L_y}{\partial T}\right)_P + \frac{1}{L_z}\left(\frac{\partial\, L_z}{\partial T}\right)_P$$

$$= 3\,\delta_T$$

This of course assumes isotropic properties (the same in all directions).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.46

Determine the volume expansivity, α_P, and the isothermal compressibility, β_T, for water at 20°C, 5 MPa and at 300°C, and 15 MPa using the steam tables.

Water at 20°C, 5 MPa (compressed liquid)

$$\alpha_P = \frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_P \approx \frac{1}{v}\left(\frac{\Delta v}{\Delta T}\right)_P \; ; \qquad \beta_T = -\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_T \approx -\frac{1}{v}\left(\frac{\Delta v}{\Delta P}\right)_T$$

Estimate by finite difference using values at 0°C, 20°C and 40°C,

$$\alpha_P \approx \frac{1}{0.000\,9995}\frac{0.001\,0056 - 0.000\,9977}{40 - 0} = \mathbf{0.000\,1976\ ^oC^{-1}}$$

Using values at saturation, 5 MPa and 10 MPa,

$$\beta_T \approx -\frac{1}{0.000\,9995}\frac{0.000\,9972 - 0.001\,0022}{10 - 0.0023} = \mathbf{0.000\,50\ MPa^{-1}}$$

Water at 300°C, 15 MPa (compressed liquid)

$$\alpha_P \approx \frac{1}{0.001\,377}\frac{0.001\,4724 - 0.001\,3084}{320 - 280} = \mathbf{0.002\,977\ ^oC^{-1}}$$

$$\beta_T \approx -\frac{1}{0.001\,377}\frac{0.001\,3596 - 0.001\,3972}{20 - 10} = \mathbf{0.002\,731\ MPa^{-1}}$$

12.47

Use the CATT3 software to solve the previous problem.

The benefit of the software to solve for the partial derivatives is that we can narrow the interval over which we determine the slope.

Water at 20°C, 5 MPa (compressed liquid)

$$\alpha_P = \frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_P \approx \frac{1}{v}\left(\frac{\Delta v}{\Delta T}\right)_P \; ; \qquad \beta_T = -\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_T \approx -\frac{1}{v}\left(\frac{\Delta v}{\Delta P}\right)_T$$

Estimate by finite difference using values at 19°C, 20°C and 21°C,

$$\alpha_P \approx \frac{1}{0.000\ 9995}\frac{0.000\ 9997 - 0.000\ 9993}{21 - 19} = \mathbf{0.000\ 40\ ^oC^{-1}}$$

Using values at saturation, 4.5 MPa and 5.5 MPa,

$$\beta_T \approx -\frac{1}{0.000\ 9995}\frac{0.000\ 9993 - 0.000\ 9997}{5.5 - 4.5} = \mathbf{0.000\ 40\ MPa^{-1}}$$

Water at 300°C, 15 MPa (compressed liquid)

$$\alpha_P \approx \frac{1}{0.001\ 377}\frac{0.001\ 385 - 0.001\ 369}{302 - 298} = \mathbf{0.011\ 619\ ^oC^{-1}}$$

$$\beta_T \approx -\frac{1}{0.001\ 377}\frac{0.001\ 373 - 0.001\ 381}{16 - 14} = \mathbf{0.002\ 905\ MPa^{-1}}$$

12.48

A cylinder fitted with a piston contains liquid methanol at 20°C, 100 kPa and volume 10 L. The piston is moved, compressing the methanol to 20 MPa at constant temperature. Calculate the work required for this process. The isothermal compressibility of liquid methanol at 20°C is 1.22×10^{-9} m^2/N.

$$ {}_1w_2 = \int_1^2 Pdv = \int P\left(\frac{\partial v}{\partial P}\right)_T dP_T = -\int_1^2 v\beta_T \, PdP_T $$

For $v \approx$ constant & $\beta_T \approx$ constant the integral can be evaluated

$$ {}_1w_2 = -\frac{v\beta_T}{2}\left(P_2^2 - P_1^2\right) $$

For liquid methanol, from Table A.4: $\rho = 787$ m^3/kg

$V_1 = 10$ L, $m = 0.01 \times 787 = 7.87$ kg

$$ {}_1W_2 = \frac{0.01 \times 1220}{2}\left[(20)^2 - (0.1)^2\right] = 2440 \text{ J} = \mathbf{2.44 \text{ kJ}} $$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.49

For commercial copper at 25°C (see table A.3) the speed of sound is about 4800 m/s. What is the adiabatic compressibility β_s?

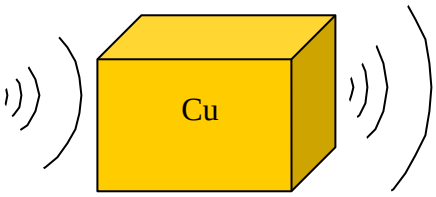
From Eq.12.41 and Eq.12.40

$$c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s = \frac{1}{-\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_s \rho} = \frac{1}{\beta_s \rho}$$

Then we get using density from Table A.3

$$\beta_s = \frac{1}{c^2\rho} = \frac{1}{4800^2 \times 8300} \frac{s^2\, m^3}{m^2\, kg} = \frac{1000}{4800^2 \times 8300} \frac{1}{kPa}$$

$$= \mathbf{5.23 \times 10^{-9}\ kPa^{-1}}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.50

Use Eq. 12.32 to solve for $(\partial T/\partial P)_s$ in terms of T, v, C_p and α_p. How large a temperature change does 25°C water ($\alpha_p = 2.1 \times 10^{-4}$ K^{-1}) have, when compressed from 100 kPa to 1000 kPa in an isentropic process?

From Eq.12.32 we get for constant s (ds = 0) and Eq.12.37

$$\left(\frac{\partial T}{\partial P}\right)_s = \frac{T}{C_p}\left(\frac{\partial v}{\partial T}\right)_P = \frac{T}{C_p}\alpha_p\, v$$

Assuming the derivative is constant for the isentropic compression we estimate with heat capacity from Table A.3 and v from B.1.1

$$\Delta T_s = \left(\frac{\partial T}{\partial P}\right)_s \Delta P_s = \frac{T}{C_p}\alpha_p\, v\, \Delta P_s$$

$$= \frac{273.15 + 25}{4.18} \times 2.1 \times 10^{-4} \times 0.001003 \times (1000 - 100)$$

$$= \mathbf{0.013\ K}$$ barely measurable.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.51

Sound waves propagate through a media as pressure waves that cause the media to go through isentropic compression and expansion processes. The speed of sound c is defined by $c^2 = (\partial P/\partial \rho)_s$ and it can be related to the adiabatic compressibility, which for liquid ethanol at 20°C is 9.4×10^{-10} m^2/N. Find the speed of sound at this temperature.

$$c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s = \frac{1}{-\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_s \rho} = \frac{1}{\beta_s \rho}$$

From Table A.4 for ethanol, $\rho = 783$ kg/m^3

$$\Rightarrow \quad c = \left(\frac{1}{940 \times 10^{-12} \times 783}\right)^{1/2} = \mathbf{1166\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.52

Use Table B.3 to find the speed of sound for carbon dioxide at 2500 kPa near 100°C. Approximate the partial derivative numerically.

$$c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s$$

We will use the 2000 kPa and 3000 kPa table entries. We need to find the change in v between two states with the same s at those two pressures.

At 100°C, 2500 kPa: s = (1.6843 + 1.5954)/2 = 1.63985 kJ/kg-K,
v = (0.03359 + 0.02182)/2 = 0.027705 m^3/kg

2000 kPa, s = 1.63985 kJ/kg-K: v = 0.031822 m^3/kg
3000 kPa, s = 1.63985 kJ/kg-K: v = 0.0230556 m^3/kg

$$c^2 \approx -v^2\left(\frac{\Delta P}{\Delta v}\right)_s = -\,0.027705^2\,\frac{3000 - 2000}{0.0230556 - 0.031822}\,\frac{kJ}{kg} = 87\,557.8\,\frac{J}{kg}$$

$$c = \sqrt{87\,557.8} = \mathbf{295.9\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.53

Use the CATT3 software to solve the previous problem.

At 100°C, 2500 kPa: s = 1.636 kJ/kg-K, v = 0.02653 m^3/kg

101°C, s = 1.636 kJ/kg-K: v = 0.02627 m^3/kg, P = 2.531 MPa
99°C, s = 1.636 kJ/kg-K: v = 0.02679 m^3/kg, P = 2.469 MPa

$$c^2 \approx -v^2\left(\frac{\Delta P}{\Delta v}\right)_s = -\,0.02653^2\,\frac{2531 - 2469}{0.02627 - 0.02679}\,\frac{kJ}{kg} = 83\,919.5\,\frac{J}{kg}$$

$$c = \sqrt{83\,919.5} = \mathbf{289.7\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.54

Consider the speed of sound as defined in Eq. 12.41. Calculate the speed of sound for liquid water at 20°C, 2.5 MPa, and for water vapor at 200°C, 300 kPa, using the steam tables.

From Eq. 12.41: $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s$

Liquid water at 20°C, 2.5 MPa, assume

$$\left(\frac{\partial P}{\partial v}\right)_s \approx \left(\frac{\Delta P}{\Delta v}\right)_T$$

Using saturated liquid at 20°C and compressed liquid at 20°C, 5 MPa,

$$c^2 = -\left(\frac{0.001\,002+0.000\,9995}{2}\right)^2\left(\frac{5-0.0023}{0.000\,9995-0.001\,002}\right)\frac{MJ}{kg}$$

$$= 2.002\times10^6\,\frac{J}{kg}$$

$$\Rightarrow \quad c = \mathbf{1415\ m/s}$$

Superheated vapor water at 200°C, 300 kPa

$$v = 0.7163\ m^3/kg, \quad s = 7.3115\ kJ/kg\ K$$

At P = 200 kPa & s = 7.3115 kJ/kg K: T = 157°C, v = 0.9766 m^3/kg

At P = 400 kPa & s = 7.3115 kJ/kg K: T = 233.8°C, v = 0.5754 m^3/kg

$$c^2 = -(0.7163)^2\left(\frac{0.400-0.200}{0.5754-0.9766}\right)\frac{MJ}{kg} = 0.2558\times10^6\ m^2/s^2$$

$$\Rightarrow \quad c = \mathbf{506\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.55

Use the CATT3 software to solve the previous problem.

From Eq. 12.41: $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s$

Liquid water at 20°C, 2.5 MPa, assume $\left(\frac{\partial P}{\partial v}\right)_s \approx \left(\frac{\Delta P}{\Delta v}\right)_s$

and CATT3: $v = 0.001001\ m^3/kg$, $s = 0.2961\ kJ/kg\text{-}K$

Using liquid at 3 MPa and 2 MPa at the same s = 0.2961 kJ/kg-K,

$$c^2 = -\,0.001001^2 \left(\frac{3 - 2}{0.001 - 0.001\,001}\right)\frac{MJ}{kg}$$

$$= 1.002\times10^6\,\frac{J}{kg}$$

$$\Rightarrow \quad c = \mathbf{1001\ m/s}$$

Superheated vapor water at 200°C, 300 kPa

CATT3: $v = 0.7163\ m^3/kg$, $s = 7.311\ kJ/kg\ K$

At P = 290 kPa & s = 7.311 kJ/kg K: $T = 196.2^oC$, $v = 0.7351\ m^3/kg$

At P = 310 kPa & s = 7.311 kJ/kg K: $T = 203.7^oC$, $v = 0.6986\ m^3/kg$

$$c^2 = -(0.7163)^2\left(\frac{0.310 - 0.290}{0.6986 - 0.7351}\right)\frac{MJ}{kg} = 0.28114 \times 10^6\ m^2/s^2$$

$$\Rightarrow \quad c = \mathbf{530\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.56

Soft rubber is used as a part of a motor mounting. Its adiabatic bulk modulus is $B_s = 2.82 \times 10^6$ kPa, and the volume expansivity is $\alpha_p = 4.86 \times 10^{-4}\ K^{-1}$. What is the speed of sound vibrations through the rubber, and what is the relative volume change for a pressure change of 1 MPa?

From Eq.12.41 and Eq.12.40

$$c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s = \frac{1}{-\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_s \rho} = \frac{1}{\beta_s \rho} = \frac{B_s}{\rho}$$

$$= 2.82 \times 10^6 \times 1000 \text{ Pa} / 1100 \text{ kg/m}^3 = 2.564 \times 10^6 \text{ m}^2/\text{s}^2$$

c = 1601 m/s

If the volume change is fast it is isentropic and if it is slow it is isothermal. We will assume it is isentropic

$$\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_s = -\beta_s = -\frac{1}{B_s}$$

then

$$\frac{\Delta V}{V} = -\frac{\Delta P}{B_s} = -\frac{1000}{2.82 \times 10^6} = \mathbf{-3.55 \times 10^{-4}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.57

Liquid methanol at 25°C has an adiabatic compressibility of 1.05×10^{-9} m^2/N. What is the speed of sound? If it is compressed from 100 kPa to 10 MPa in an insulated piston/cylinder, what is the specific work?

From Eq.12.41 and Eq.12.40 and the density from table A.4

$$c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s = \frac{1}{\beta_s \rho} = \frac{1}{1.05 \times 10^{-9} \times 787}$$

$$= 1.210 \times 10^6 \ \text{m}^2/\text{s}^2$$

$$c = \mathbf{1100\ m/s}$$

The specific work becomes

$$w = \int P\, dv = \int P\, (-\beta_s v)\, dP = -\int \beta_s v\, P\, dP = -\beta_s\, v \int_1^2 P\, dP$$

$$= -\beta_s\, v\, 0.5\, (P_2^2 - P_1^2)$$

$$= -1.05 \times 10^{-9}\ \text{m}^2/\text{N} \times \frac{0.5}{787}\ \text{m}^3/\text{kg} \times (10\,000^2 - 100^2) \times 1000^2\ \text{Pa}^2$$

$$= \mathbf{-66.7\ J/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.58

Use Eq. 12.32 to solve for $(\partial T/\partial P)_s$ in terms of T, v, C_p and α_p. How much higher does the temperature become for the compression of the methanol in Problem 12.57? Use $\alpha_p = 2.4 \times 10^{-4}\ K^{-1}$ for methanol at 25°C.

From Eq.12.32 we get for constant s (ds = 0) and Eq.12.37

$$\left(\frac{\partial T}{\partial P}\right)_s = \frac{T}{C_p}\left(\frac{\partial v}{\partial T}\right)_P = \frac{T}{C_p}\alpha_p\, v$$

Assuming the derivative is constant for the isentropic compression we estimate with heat capacity and density ($v = 1/\rho$) from Table A.4

$$\Delta T_s = \left(\frac{\partial T}{\partial P}\right)_s \Delta P_s = \frac{T}{C_p}\alpha_p\, v\, \Delta P_s$$

$$= \frac{298.15}{2.55}\frac{\text{K kg K}}{\text{kJ}} \times 2.4 \times 10^{-4}\ \text{K}^{-1} \times \frac{1}{787}\frac{\text{m}^3}{\text{kg}} \times (10\,000 - 100)\ \text{kPa}$$

$$= \mathbf{0.353\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.59

Find the speed of sound for air at 20°C, 100 kPa using the definition in Eq. 12.41 and relations for polytropic processes in ideal gases.

From problem 12.41 : $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s$

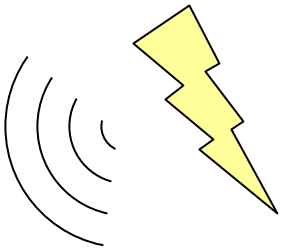
For ideal gas and isentropic process, Pv^k = constant

$P = Cv^{-k} \Rightarrow \frac{\partial P}{\partial v} = -kCv^{-k-1} = -kPv^{-1}$

$c^2 = -v^2(-kPv^{-1}) = kPv = kRT$

$c = \sqrt{kRT} = \sqrt{1.4 \times 0.287 \times 293.15 \times 1000}$ = **343.2 m/s**

For every 3 seconds after the lightning the sound travels about 1 km.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Equations of State

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.60

Use Table B3 and find the compressibility of carbon dioxide at the critical point.

$$Pv = Z\,RT$$

At the critical point from B.3:

$$P = 7377.3 \text{ kPa},\ T = 31°C = 304.15 \text{ K},\ v = 0.002139 \text{ m}^3/\text{kg}$$

from A.5: $R = 0.1889$ kJ/kg-K

$$Z = \frac{Pv}{RT} = \frac{7377.3 \times 0.002139}{0.1889 \times 304.15} = \mathbf{0.27}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.61

Use the equation of state as shown in Example 12.3 where changes in enthalpy and entropy were found. Find the isothermal change in internal energy in a similar fashion; do not compute it from enthalpy.

The equation of state is

$$\frac{Pv}{RT} = 1 - C' \frac{P}{T^4}$$

and to integrate for changes in u from Eq.12.31 we make it explicit in P as

$$P = T^4 \left(\frac{v}{R} T^3 + C' \right)^{-1}$$

Now perform the partial derivative of P

$$\left(\frac{\partial P}{\partial T}\right)_v = 4\, T^3 \left(\frac{v}{R} T^3 + C' \right)^{-1} - T^4 \left(\frac{v}{R} T^3 + C' \right)^{-2} 3 \frac{v}{R} T^2$$

$$= 4 \frac{P}{T} - \frac{P^2}{T^4} 3 \frac{v}{R} T^2 = 4 \frac{P}{T} - 3 \frac{P}{T} \times \frac{Pv}{RT} = \frac{P}{T} \left[4 - 3 \frac{Pv}{RT} \right]$$

Substitute into Eq.12.31

$$du_T = \left[T \left(\frac{\partial P}{\partial T}\right)_v - P \right] dv_T = \left[P\left(4 - 3 \frac{Pv}{RT} \right) - P \right] dv_T$$

$$= 3\, P \left(1 - \frac{Pv}{RT} \right) dv_T = 3\, P\, C' \frac{P}{T^4}\, dv_T$$

The P must be eliminated in terms of v or the opposite, we do the latter as from the equation of state

$$v = \frac{RT}{P} - C' R \frac{1}{T^3} \qquad \Rightarrow \qquad dv_T = -\frac{RT}{P^2} dP_T$$

so now

$$du_T = 3\, C' \frac{P^2}{T^4} dv_T = -3\, C' R \frac{1}{T^3}\, dP_T$$

and the integration becomes

$$u_2 - u_1 = -3\, C' R\, T^{-3} (P_2 - P_1)$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.62

Use Table B.4 to find the compressibility of R-410A at 60^{o}C and a) saturated liquid b) saturated vapor and c) 3000 kPa.

Table A.2: R = 8.31451 / 72.585 = 0.1145 kJ/kg-K

a) Table B.4.1: P = 3836.9 kPa, v = 0.001227 m^3/kg

$$Z = \frac{Pv}{RT} = \frac{3836.9 \times 0.001227}{0.1145 \times 333.15} = \mathbf{0.1234}$$

b) Table B.4.1: P = 3836.9 kPa, v = 0.00497 m^3/kg

$$Z = \frac{Pv}{RT} = \frac{3836.9 \times 0.00497}{0.1145 \times 333.15} = \mathbf{0.5}$$

c) Table B.4.2: P = 3000 kPa, v = 0.00858 m^3/kg

$$Z = \frac{Pv}{RT} = \frac{3000 \times 0.00858}{0.1145 \times 333.15} = \mathbf{0.675}$$

The R-410A is not an ideal gas at any of these states.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.63

Use a truncated virial EOS that includes the term with B for carbon dioxide at 20^{o} C, 1 MPa for which B = –0.128 m^3/kmol and T(dB/dT) = 0.266 m^3/kmol. Find the difference between the ideal-gas value and the real-gas value of the internal energy.

virial eq.: $P = \frac{RT}{v} + \frac{BRT}{v^2}$; $\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v} + \frac{BR}{v^2} + \frac{RT}{v^2}\left(\frac{dB}{dT}\right)$

$$u-u^* = -\int_{\infty}^{v}\left[\left(\frac{\partial P}{\partial T}\right)_v - P\right]dv = -\int_{\infty}^{v}\left[\frac{RT^2}{v^2}\left(\frac{dB}{dT}\right)\right]dv = -\frac{RT}{v}\left[T\left(\frac{dB}{dT}\right)\right]$$

Solution of virial equation (quadratic formula):

$$\bar{v} = \frac{1}{2}\frac{\bar{R}T}{P}\left[1 + \sqrt{1 + 4BP/\bar{R}T}\right] \qquad \text{where: } \frac{\bar{R}T}{P} = \frac{8.3145\times 293.15}{1000} = 2.43737$$

$$\bar{v} = \frac{1}{2} \times 2.43737 \left[1 + \sqrt{1 + 4(-0.128)/2.43737}\right] = 2.3018 \text{ m}^3/\text{kmol}$$

Using the minus-sign root of the quadratic formula results in a compressibility factor < 0.5, which is not consistent with such a truncated equation of state.

$$u - u^* = \frac{-8.3145 \times 293.15}{2.3018}\left[0.266\right] / 44.01 = - \mathbf{6.4\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.64

Solve the previous Problem with Table B.3 values and find the compressibility of the carbon dioxide at that state.

B.3: $v = 0.05236\ m^3/kg$, $u = 327.27\ kJ/kg$, A5: $R = 0.1889\ kJ/kg\text{-}K$

$$Z = \frac{Pv}{RT} = \frac{1000 \times 0.05236}{0.1889 \times 293.15} = 0.9455$$ close to ideal gas

To get u^* let us look at the lowest pressure 400 kPa, 20^oC: $v = 0.13551\ m^3/kg$ and $u = 331.57\ kJ/kg$.

$$Z = Pv/RT = 400 \times 0.13551/(0.1889 \times 293.15) = 0.97883$$

It is not very close to ideal gas but this is the lowest P in the printed table.

$$u - u^* = 327.27 - 331.57 = \mathbf{-4.3\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.65

A gas is represented by the virial EOS with the first two terms, B and C. Find an expression for the work in an isothermal expansion process in a piston-cylinder.

Virial EOS: $$P = \frac{RT}{v} + \frac{B(T)\,RT}{v^2} + \frac{C(T)\,RT}{v^3} + \ldots.$$

$$= RT[\, v^{-1} + B(T)\, v^{-2} + C(T)\, v^{-3} + ..\ ]$$

The work is $$w = \int P\, dv = RT \int [\, v^{-1} + B(T)\, v^{-2} + C(T)\, v^{-3} + ..\ ]\, dv$$

With just the first two terms we get

$$w = RT\, [\, \ln \frac{v_2}{v_1} - B(T)\, (v_2^{-1} - v_1^{-1}) - \frac{1}{2} C(T)\, (v_2^{-2} - v_1^{-2})\,]$$

12.66

Extend problem 12.63 to find the difference between the ideal-gas value and the real-gas value of the entropy and compare to table B.3.

Calculate the difference in entropy of the ideal-gas value and the real-gas value for carbon dioxide at the state 20°C, 1 MPa, as determined using the virial equation of state. Use numerical values given in Problem 12.63.

CO_2 at T = 20°C, P = 1 MPa

$$s^*_{P^*} - s_P = \int_{v(P)}^{RT/P^*} \left(\frac{\partial P}{\partial T}\right)_v dv \; ; \qquad \text{ID Gas:} \quad s^*_{P^*} - s_P = \int_{v(P)}^{RT/P^*} \frac{R}{v} dv = R \ln \frac{P}{P^*}$$

Therefore, at P: $$s^*_P - s_P = -R \ln \frac{P}{P^*} + \int_{v(P)}^{RT/P^*} \left(\frac{\partial P}{\partial T}\right)_v dv$$

virial: $$P = \frac{RT}{v} + \frac{BRT}{v^2} \quad \text{and} \quad \left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v} + \frac{BR}{v^2} + \frac{RT}{v^2}\left(\frac{dB}{dT}\right)$$

Integrating,

$$s^*_P - s_P = -R \ln \frac{P}{P^*} + R \ln \frac{RT}{P^* v} + R\left[B + T\left(\frac{dB}{dT}\right)\right]\left(\frac{1}{v} - \frac{P^*}{RT}\right)$$

$$= R\left[\ln \frac{RT}{Pv} + \left(B + T\left(\frac{dB}{dT}\right)\right)\frac{1}{v}\right]$$

Using values for CO_2 from solution 12.63 and R = 0.1889 kJ/kgK

$$s^*_P - s_P = 0.1889\left[\ln \frac{2.437\ 37}{2.3018} + \left(-0.128 + 0.266\right)\frac{1}{2.3018}\right]$$

$$= \mathbf{0.02214\ kJ/kg\ K}$$

From Table B.3 take the ideal as the lowest P = 400 kPa:

$$s^*_P - s_P = 1.7904 - 1.6025 + 0.1889 \ln(400/1000) = \mathbf{0.0148\ kJ/kgK}$$

The lowest P = 400 kPa in B3 is not exactly ideal gas (Z = Pv/RT = 0.9788)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

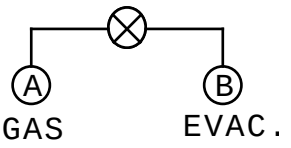
12.67

Two uninsulated tanks of equal volume are connected by a valve. One tank contains a gas at a moderate pressure P_1, and the other tank is evacuated. The valve is opened and remains open for a long time. Is the final pressure P_2 greater than, equal to, or less than $P_1/2$? Hint: Recall Fig. 12.5.

Assume the temperature stays constant then for an ideal gas the pressure will be reduced to half the original pressure. For the real gas the compressibility factor maybe different from 1 and then changes towards one as the pressure drops.

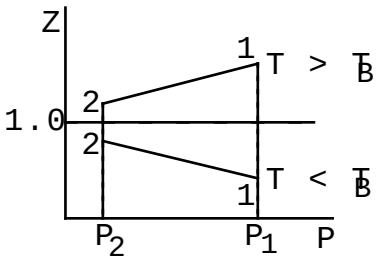
$$V_A = V_B \;\Rightarrow\; V_2 = 2V_1, \quad T_2 = T_1 = T$$

$$\frac{P_2}{P_1} = \frac{V_1}{V_2}\frac{Z_2}{Z_1}\frac{mRT}{mRT} = \frac{1}{2}\frac{Z_2}{Z_1}$$



If $T < T_B$, $Z_2 > Z_1 \;\Rightarrow\; \frac{P_2}{P_1} > \frac{1}{2}$

If $T > T_B$, $Z_2 < Z_1 \;\Rightarrow\; \frac{P_2}{P_1} < \frac{1}{2}$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.68

Show how to get the constants in Eq.12.52 for van der Waals EOS.

van der Waals EOS: $$P = \frac{RT}{v - b} - \frac{a}{v^2}$$

The conditions at the critical point relate to these derivatives

$$\left(\frac{\partial P}{\partial v}\right)_T = -\frac{RT}{(v-b)^2} + \frac{2a}{v^3} \quad ; \quad \left(\frac{\partial^2 P}{\partial v^2}\right)_T = \frac{2RT}{(v-b)^3} - \frac{6a}{v^4}$$

Set both derivatives to zero at the critical point

$$-\frac{RT_c}{(v_c - b)^2} + \frac{2a}{v_c^3} = 0 \quad (1) \; ; \qquad \frac{2RT_c}{(v_c - b)^3} - \frac{6a}{v_c^4} = 0 \quad (2)$$

we also have from the EOS

$$P_c = \frac{RT_c}{v_c - b} - \frac{a}{v_c^2} \qquad (3)$$

Now we need to solve theses three equations for v_c, a and b. Solve the first equation for a and substitute into the second equation to give

$$\frac{2a}{v_c^3} = \frac{RT_c}{(v_c - b)^2} \quad \Rightarrow \quad \frac{6a}{v_c^4} = \frac{3RT_c}{v_c\,(v_c - b)^2} \qquad \text{substitute into Eq.(2)}$$

$$\frac{3RT_c}{v_c\,(v_c - b)^2} = \frac{2RT_c}{(v_c - b)^3} \qquad \text{now solve to get} \qquad v_c = 3b$$

Substitute back into the first equation to get

$$2\,a = \frac{RT_c}{(v_c - b)^2}\, v_c^3 = RT_c\, \frac{27}{4}\, b$$

Now finally substitute a and v_c into the EOS Eq.(3) to get b.

$$P_c = \frac{RT_c}{v_c - b} - \frac{a}{v_c^2} = \frac{RT_c}{2b} - \frac{RT_c\, \frac{27}{8}\, b}{9\, b^2} = RT_c\,(0.5 - 3/8)\,/b$$

The result is as in Eq.12.52.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.69

Show that the van der Waals equation can be written as a cubic equation in the compressibility factor involving the reduced pressure and reduced temperature as

$$Z^3 - \left(\frac{P_r}{8T_r} + 1\right) Z^2 + \left(\frac{27\, P_r}{64\, T_r^2}\right) Z - \frac{27\, P_r^{\,2}}{512\, T_r^{\,3}} = 0$$

van der Waals equation, Eq.12.55: $P = \dfrac{RT}{v-b} - \dfrac{a}{v^2}$

$$a = \frac{27}{64}\frac{R^2 T_C^{\,2}}{P_C} \qquad b = \frac{RT_C}{8P_C}$$

multiply equation by $\dfrac{v^2(v-b)}{P}$

Get: $v^3 - (b + \dfrac{RT}{P})\, v^2 + (\dfrac{a}{P})\, v - \dfrac{ab}{P} = 0$

Multiply by $\dfrac{P^3}{R^3\, T^3}$ and substitute $Z = \dfrac{Pv}{RT}$

Get: $Z^3 - (\dfrac{bP}{RT} + 1)\, Z^2 + (\dfrac{aP}{R^2T^2})\, Z - (\dfrac{abP^2}{R^3\, T^3}) = 0$

Substitute for a and b, get:

$$Z^3 - \left(\frac{P_r}{8T_r} + 1\right) Z^2 + \left(\frac{27\, P_r}{64\, T_r^2}\right) Z - \frac{27\, P_r^{\,2}}{512\, T_r^{\,3}} = 0$$

Where $P_r = \dfrac{P}{P_c}$, $T_r = \dfrac{T}{T_c}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.70

Evaluate changes in an isothermal process for u, h and s for a gas with an equation of state as P (v – b) = RT.

From Eq.12.31 we get

$$du_T = [\ T \left(\frac{\partial P}{\partial T}\right)_v - P\ ]\ dv_T = [\ T\ (\frac{R}{v-b}) - P\ ]\ dv_T = [\ P - P]\ dv_T = 0$$

From Eq.12.27 we get using v = b + RT/P

$$dh_T = [\ v - T \left(\frac{\partial v}{\partial T}\right)_P\ ]\ dP_T = [\ v - T\ (\frac{R}{P})\ ]\ dP_T = \ b\ dP_T$$

From Eq.12.32 or Eq.12.34 we get

$$ds_T = - \left(\frac{\partial v}{\partial T}\right)_P dP_T \ = \ \left(\frac{\partial P}{\partial T}\right)_v dv_T$$

$$= - \frac{R}{P} dP_T \ = \ \frac{R}{v-b} dv_T$$

Now the changes in u, h and s can be integrated to find

$$u_2 - u_1 = 0$$

$$h_2 - h_1 = \int b\ dP = b(P_2 - P_1)$$

$$s_2 - s_1 = -R \ln \frac{P_2}{P_1} = R \ln \frac{v_2 - b}{v_1 - b}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.71

Develop expressions for isothermal changes in internal energy, enthalpy and entropy for a gas obeying the van der Waals equation of state.

van der Waals equation of state: $P = \frac{RT}{v-b} - \frac{a}{v^2}$

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v-b}$$

$$\left(\frac{\partial u}{\partial v}\right)_T = T\left(\frac{\partial P}{\partial T}\right)_v - P = \frac{RT}{v-b} - \frac{RT}{v-b} + \frac{a}{v^2}$$

$$(u_2-u_1)_T = \int_1^2 [T\left(\frac{\partial P}{\partial T}\right)_v - P]dv = \int_1^2 \frac{a}{v^2}dv = a(\frac{1}{v_1} - \frac{1}{v_2})$$

$$(h_2-h_1)_T = (u_2-u_1)_T + P_2v_2 - P_1v_1 = P_2v_2 - P_1v_1 + a(\frac{1}{v_1} - \frac{1}{v_2})$$

$$(s_2-s_1)_T = \int_1^2 \left(\frac{\partial P}{\partial T}\right)_v dv = \int_1^2 \frac{R}{v-b}dv = R \ln\left(\frac{v_2-b}{v_1-b}\right)$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.72

Consider the following equation of state, expressed in terms of reduced pressure and temperature: $Z = 1 + (P_r/14T_r)[1 - 6T_r^{-2}]$. What does this predict for the reduced Boyle temperature?

$$Z = \frac{Pv}{RT} = 1 + \frac{P_r}{14\,T_r}\left(1 - \frac{6}{T_r^{\,2}}\right)$$

$$\left(\frac{\partial Z}{\partial P}\right)_T = \frac{1}{14 P_c T_r}\left(1 - \frac{6}{T_r^{\,2}}\right)$$

To find the Boyle temperature we must have

$$\lim_{P \to 0} \left(\frac{\partial Z}{\partial P}\right)_T = 0 \quad \text{at } T_{boyle}$$

The above derivative is then zero if:

$$\left(1 - \frac{6}{T_r^{\,2}}\right) = 0 \quad \rightarrow \quad T_r = \sqrt{6} = \mathbf{2.45}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.73

Use the result of Problem 12.35 to find the reduced temperature at which the Joule-Thomson coefficient is zero, for a gas that follows the EOS given in Problem 12.72

$$Z = \frac{Pv}{RT} = 1 + \frac{P_r}{14\,T_r}\left(1 - \frac{6}{T_r^{\,2}}\right)$$

From Problem 12.35

$$\mu_J = \left(\frac{\partial T}{\partial P}\right)_h = \frac{T\left(\frac{\partial v}{\partial T}\right)_P - v}{C_P} = \frac{RT^2}{PC_P}\left(\frac{\partial Z}{\partial T}\right)_P$$

$$\left(\frac{\partial Z}{\partial T}\right)_P = -\frac{P_r}{14T_c}\,T_r^{-2}\left(1 - 6\,T_r^{-2}\right) + \frac{P_r}{14\,T_r}\left(12\;T_r^{-3}/T_c\right)$$

$$= \frac{P_r}{14T_c}\,T_r^{-2}\;(18\,T_r^{-2} - 1)$$

So this is zero for $18\,T_r^{-2} = 1$ or

$$T_r = \sqrt{18}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.74

What is the Boyle temperature for the following equation of state: $P = \frac{RT}{v-b} - \frac{a}{v^2 T}$ where a and b are constants.

$$P = \frac{RT}{v-b} - \frac{a}{v^2 T}$$

Multiplying by $\frac{v-b}{P}$ gives: $v - b = \frac{RT}{P} - \frac{a(1-b/v)}{PvT}$

Using for T_{Boyle}:

$$\lim_{P\to 0}\left(\frac{\partial Z}{\partial P}\right)_T = \lim_{P\to 0}\frac{Z-1}{P-0} = \frac{1}{RT}\lim_{P\to 0}\left(v - \frac{RT}{P}\right)$$

$$\lim_{P\to 0}\left(v - \frac{RT}{P}\right) = b - \frac{a(1-0)}{RT\times T} = b - \frac{a}{RT^2} = 0 \text{ at } T_{Boyle}$$

$$\text{or} \quad T_{Boyle} = \sqrt{\frac{a}{Rb}} = \sqrt{\frac{27}{64}\frac{R^2 T_C^3}{P_C}\frac{1}{R}\frac{8P_C}{RT_C}} = \sqrt{\frac{\mathbf{27}}{\mathbf{8}}}\,\mathbf{T_C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.75

Determine the reduced Boyle temperature as predicted by an equation of state (the experimentally observed value for most substances is about 2.5), using the van der Waals equation and the Redlich–Kwong equation. Note: It is helpful to use Eqs. 12.47 and 12.48 in addition to Eq. 12.46

The Boyle temp. is that T at which $\lim_{P\to 0}\left(\frac{\partial Z}{\partial P}\right)_T = 0$

But $\lim_{P\to 0}\left(\frac{\partial Z}{\partial P}\right)_T = \lim_{P\to 0}\frac{Z-1}{P-0} = \frac{1}{RT}\lim_{P\to 0}\left(v - \frac{RT}{P}\right)$

van der Waals: $P = \frac{RT}{v-b} - \frac{a}{v^2}$

multiply by $\frac{v-b}{P}$, get

$v-b = \frac{RT}{P} - \frac{a(v-b)}{Pv^2}$ or $v - \frac{RT}{P} = b - \frac{a(1-b/v)}{Pv}$

& $RT \times \lim_{P\to 0}\left(\frac{\partial Z}{\partial P}\right)_T = b - \frac{a(1-0)}{RT} = 0$ only at T_{Boyle}

or $T_{Boyle} = \frac{a}{Rb} = \frac{27}{8}T_C = \mathbf{3.375\ T_C}$

Redlich-Kwong: $P = \frac{RT}{v-b} - \frac{a}{v(v+b)T^{1/2}}$

as in the first part, get

$v - \frac{RT}{P} = b - \frac{a(1-b/v)}{Pv(1+b/v)T^{1/2}}$

& $RT \times \lim_{P\to 0}\left(\frac{\partial Z}{\partial P}\right)_T = b - \frac{a(1-0)}{Pv(1+0)T^{1/2}} = 0$ only at T_{Boyle}

or $T_{Boyle}^{3/2} = \frac{a}{Rb} = \frac{0.427\,48\,R^2\,T_C^{5/2}}{RP_C} \times \frac{P_C}{0.08\,664\,R\,T_C}$

$T_{Boyle} = \left(\frac{0.427\,48}{0.086\,64}\right)^{2/3} T_C = \mathbf{2.9\ T_C}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.76

One early attempt to improve on the van der Waals equation of state was an expression of the form

$$P = \frac{RT}{v-b} - \frac{a}{v^2 T}$$

Solve for the constants *a*, *b*, and v_C using the same procedure as for the van der Waals equation.

From the equation of state take the first two derivatives of P with v:

$$\left(\frac{\partial P}{\partial v}\right)_T = -\frac{RT}{(v-b)^2} + \frac{2a}{v^3 T} \quad \text{and} \quad \left(\frac{\partial^2 P}{\partial v^2}\right)_T = -\frac{2RT}{(v-b)^3} - \frac{6a}{v^4 T}$$

Since both these derivatives are zero at the critical point:

$$-\frac{RT}{(v-b)^2} + \frac{2a}{v^3 T} = 0 \qquad \text{and} \qquad -\frac{2RT}{(v-b)^3} - \frac{6a}{v^4 T} = 0$$

Also, $$P_C = \frac{RT_C}{v_C - b} - \frac{a}{v_C^2 T_C}$$

solving these three equations:

$$v_C = 3b, \quad a = \frac{27}{64}\frac{R^2 T_C^3}{P_C}, \qquad b = \frac{RT_C}{8P_C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.77

Develop expressions for isothermal changes in internal energy, enthalpy and entropy for a gas obeying Redlich-Kwong equation of state.

Redlich-Kwong equation of state: $P = \frac{RT}{v - b} - \frac{a}{v(v + b)T^{1/2}}$

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v - b} + \frac{a}{2v(v + b)T^{3/2}}$$

From Eq.12.31

$$(u_2 - u_1)_T = \int_1^2 \frac{3a}{2v(v + b)T^{1/2}}\, dv = \frac{-3a}{2bT^{1/2}} \ln\left[\left(\frac{v_2 + b}{v_2}\right)\left(\frac{v_1}{v_1 + b}\right)\right]$$

We find change in h from change in u, so we do not do the derivative in Eq.12.27. This is due to the form of the EOS.

$$(h_2 - h_1)_T = P_2v_2 - P_1v_1 - \frac{3a}{2bT^{1/2}} \ln\left[\left(\frac{v_2 + b}{v_2}\right)\left(\frac{v_1}{v_1 + b}\right)\right]$$

Entropy follows from Eq.12.35

$$(s_2 - s_1)_T = \int_1^2 \left[\frac{R}{v - b} + \frac{a/2}{v(v + b)T^{3/2}}\right] dv$$

$$= R \ln\left(\frac{v_2 - b}{v_1 - b}\right) - \frac{a}{2bT^{3/2}} \ln\left[\left(\frac{v_2 + b}{v_2}\right)\left(\frac{v_1}{v_1 + b}\right)\right]$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.78

Determine the second virial coefficient B(T) using the van der Waals equation of state. Also find its value at the critical temperature where the experimentally observed value is about $-0.34\ RT_c/P_c$.

From Eq.12.48: $B(T) = -\lim_{P\to 0} \alpha$ where Eq. 12.44: $\alpha = \frac{RT}{P} - v$

From Eq. 12.51:

van der Waals: $P = \frac{RT}{v-b} - \frac{a}{v^2}$ which we can multiply by $\frac{v-b}{P}$, get

$$v - b = \frac{RT}{P} - \frac{a(v-b)}{Pv^2} \quad \text{or} \quad v - \frac{RT}{P} = b - \frac{a(1-b/v)}{Pv}$$

Taking the limit for P -> 0 then (Pv -> RT and v -> ∞) we get :

$$B(T) = b - a/RT = \frac{RT_C}{P_C}\left(\frac{1}{8} - \frac{27\ T_C}{64\ T}\right)$$

where a,b are from Eq.12.52. At $T = T_C$ then we have

$$B(T_C) = \frac{RT_C}{P_C}\left(-\frac{19}{64}\right) = -0.297\ \frac{RT_C}{P_C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.79

Determine the second virial coefficient B(T) using the Redlich-Kwong equation of state. Also find its value at the critical temperature where the experimentally observed value is about $-0.34\ RT_c/P_c$.

From Eq.12.48: $B(T) = -\lim_{P\to 0} \alpha$ where Eq.12.44: $\alpha = \frac{RT}{P} - v$

For Redlich Kwong the result becomes

$$v - \frac{RT}{P} = b - \frac{a(1- b/v)}{Pv(1 + b/v)\ T^{1/2}}$$

Taking the limit for P -> 0 then (Pv -> RT and v -> ∞) we get :

$$\Rightarrow \quad B(T) = b - \frac{a}{RT^{3/2}}$$

Now substitute Eqs. 12.54 and 12.55 for a and b,

$$B(T) = \frac{RT_C}{P_C}\left[0.08664 - 0.42748\left(\frac{T_C}{T}\right)^{3/2}\right]$$

and evaluated at T_C it becomes

$$B(T_C) = \frac{RT_C}{P_C}\left[0.08664 - 0.42748\right] = -0.341\ \frac{RT_C}{P_C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.80

Oxygen in a rigid tank with 1 kg is at 160 K, 4 MPa. Find the volume of the tank by iterations using the Redlich-Kwong EOS. Compare the result with the ideal gas law.

For the ideal gas law: $Pv = RT$ so $v = RT/P$

$v = 0.2598 \times 160 / 4000 = 0.0104$ m^3/kg ; $V = mv =$ **0.0104 m^3**

For Redlich-Kwong, Eq.12.53 and oxygen

$P_c = 5040$ kPa; $T_c = 154.6$ K; $R = 0.2598$ kJ/kg K

$$b = 0.08664 \frac{RT_c}{P_c} = 0.08664 \times \frac{0.2598 \times 154.6}{5040} = 0.000\,690\,5 \text{ m}^3/\text{kg}$$

$$a = 0.427\,48 \frac{R^2 T_c^{5/2}}{P_c} = 0.427\,48 \times \frac{0.2598^2 \times 154.6^{5/2}}{5040} = 1.7013$$

$$P = \frac{RT}{v - b} - \frac{a}{v(v + b)T^{1/2}}$$ trial and error to get v due to nonlinearity

$v = 0.01$ m^3/kg $\Rightarrow$ $P = 4465.1 - 1279.9 = 3185.2$ kPa too low

$v = 0.008$ m^3/kg $\Rightarrow$ $P = 5686.85 - 1968.1 = 3718.8$ kPa too low

$v = 0.0075$ m^3/kg $\Rightarrow$ $P = 6104.41 - 2227.43 = 3876.98$ kPa

$v = 0.007$ m^3/kg $\Rightarrow$ $P = 6588.16 - 2541.70 = 4046.46$ kPa

Now we interpolate between the last two entries and check

$v = 0.00714$ m^3/kg $\Rightarrow$ $P = 6445.15 - 2447.3 = 3997.8$ kPa OK

$V = mv =$ **0.00714 m^3** (69% of the ideal gas value)

12.81

A flow of oxygen at 230 K, 5 MPa is throttled to 100 kPa in a steady flow process. Find the exit temperature and the specific entropy generation using Redlich-Kwong equation of state and ideal gas heat capacity. Notice this becomes iterative due to the non-linearity coupling *h, P, v* and *T*.

C.V. Throttle. Steady single flow, no heat transfer and no work.

Energy eq.: $h_1 + 0 = h_2 + 0$ so constant h

Entropy Eq.: $s_1 + s_{gen} = s_2$ so entropy generation

Find the change in h from Eq.12.26 assuming C_p is constant.

Redlich-Kwong equation of state: $$P = \frac{RT}{v - b} - \frac{a}{v(v + b)T^{1/2}}$$

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v - b} + \frac{a}{2v(v + b)T^{3/2}}$$

From Eq.12.31

$$(u_2 - u_1)_T = \int_1^2 \frac{3a}{2v(v + b)T^{1/2}}\,dv = \frac{-3a}{2bT^{1/2}} \ln\left[\left(\frac{v_2 + b}{v_2}\right)\left(\frac{v_1}{v_1 + b}\right)\right]$$

We find change in h from change in u, so we do not do the derivative in Eq.12.27. This is due to the form of the EOS.

$$(h_2 - h_1)_T = P_2v_2 - P_1v_1 - \frac{3a}{2bT^{1/2}} \ln\left[\left(\frac{v_2 + b}{v_2}\right)\left(\frac{v_1}{v_1 + b}\right)\right]$$

Entropy follows from Eq.12.35

$$(s_2 - s_1)_T = \int_1^2 \left[\frac{R}{v - b} + \frac{a/2}{v(v + b)T^{3/2}}\right] dv$$

$$= R \ln\left(\frac{v_2 - b}{v_1 - b}\right) - \frac{a}{2bT^{3/2}} \ln\left[\left(\frac{v_2 + b}{v_2}\right)\left(\frac{v_1}{v_1 + b}\right)\right]$$

$P_c = 5040$ kPa; $T_c = 154.6$ K; $R = 0.2598$ kJ/kg K

$$b = 0.08664 \frac{RT_c}{P_c} = 0.08664 \times \frac{0.2598 \times 154.6}{5040} = 0.000\,690\,5 \text{ m}^3/\text{kg}$$

$$a = 0.427\,48 \frac{R^2T_c^{5/2}}{P_c} = 0.427\,48 \times \frac{0.2598^2 \times 154.6^{5/2}}{5040} = 1.7013$$

We need to find T_2 so the energy equation is satisfied

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$h_2 - h_1 = h_2 - h_x + h_x - h_1 = C_p(T_2 - T_1) + (h_2 - h_1)_T = 0$$

and we will evaluate it similar to Fig. 12.4, where the first term is done from state x to 2 and the second term is done from state 1 to state x (at T_1 = 230 K). We do this as we assume state 2 is close to ideal gas, but we do not know T_2.

We first need to find v_1 from the EOS, so guess v and find P

$v_1 = 0.011$ m^3/kg $\Rightarrow$ P = 5796.0 – 872.35 = 4924 too low

$v_1 = 0.01082$ m^3/kg $\Rightarrow$ P = 5899.0 – 900.7 = 4998.3 OK

Now evaluate the change in h along the 230 K from state 1 to state x, that requires a value for v_x. Guess ideal gas at T_x = 230 K,

$$v_x = RT_x/P_2 = 0.2598 \times 230/100 = 0.59754 \text{ m}^3/\text{kg}$$

From the EOS: P_2 = 100.1157 – 0.3138 = 99.802 kPa (close)

A few more guesses and adjustments gives

$v_x = 0.59635$ m^3/kg; P_2 = 100.3157 – 0.3151 = 100.0006 kPa OK

$$(h_x - h_1)_T = P_x v_x - P_1 v_1 - \frac{3a}{2bT^{1/2}} \ln\left[\left(\frac{v_x + b}{v_x}\right)\left(\frac{v_1}{v_1 + b}\right)\right]$$

$$= 59.635 - 5000 \times 0.01082 - 243.694 \ln\left[\frac{0.59704}{0.59635} \times \frac{0.01082}{0.01151}\right]$$

$$= 59.635 - 54.1 + 14.78335 = 20.318 \text{ kJ/kg}$$

From energy eq.: $T_2 = T_1 - (h_x - h_1)_T/C_p = 230 - 20.318 / 0.922 =$ **208 K**

Now the change in s is done in a similar fashion,

$$s_{gen} = s_2 - s_1 = (s_x - s_1)_T + s_2 - s_x$$

$$= R \ln\left(\frac{v_x - b}{v_1 - b}\right) - \frac{a}{2bT^{3/2}} \ln\left[\left(\frac{v_x + b}{v_x}\right)\left(\frac{v_1}{v_1 + b}\right)\right] + C_p \ln \frac{T_2}{T_x}$$

$$= 0.2598 \ln\left(\frac{0.59566}{0.0101295}\right) - 0.35318 \ln (0.94114) + 0.922 \ln\left(\frac{208}{230}\right)$$

$$= 1.05848 + 0.021425 - 0.092699$$

$$= \mathbf{0.987 \text{ kJ/kg K}}$$

12.82

How low should the pressure be so that nitrous oxide (N_2O) gas at 278.6 K can be treated as an ideal gas with 5% accuracy or better?

From Table A.2: $T_c = 309.6$ K, $P_c = 7.24$ MPa => $T_{r1} = \dfrac{278.6}{309.6} = 0.9$

Look in Fig. D.1 following the curve $T_{r1} = 0.9$ to the point where Z = 0.95

$$P_{r1} = 0.125$$

so

$$P < 0.125 \times 7.24 \text{ MPa} = 0.9 \text{ MPA} = \mathbf{900\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.83

Nitrous oxide (N_2O) at 278.6 K is at a pressure so that it can be in a two-phase state. Find the generalized enthalpy departure for the two saturated states of liquid and vapor.

From Table A.2: $T_c = 309.6$ K, $P_c = 7.24$ MPa => $T_{r1} = \frac{278.6}{309.6} = 0.9$

From Fig. D.2:

Saturated liquid: $(h^* - h_f)/RT_c = 4.08$;

Saturated vapor: $(h^* - h_g)/RT_c = 0.875$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.84

Find the heat of evaporation, h_{fg}, for R-134a at 0°C from the generalized charts and compare to the value in Table B.5.

From Table A.2: $T_c = 374.2$ K, $P_c = 4.06$ MPa => $T_{r1} = \dfrac{273.15}{374.2} = 0.73$

From Fig. D.2:

Saturated liquid: $(h^* - h_f)/RT_c = 4.7$;

Saturated vapor: $(h^* - h_g)/RT_c = 0.3$

$h_{fg} = h_g - h_f = RT_c\,[-0.3 - (-4.7)] = 4.4\ RT_c$

$= 4.4 \times 0.08149 \times 374.2 =$ **134.2 kJ/kg**

Table B.5.1: $h_{fg} =$ **198.36 kJ/kg**

The approximation is not very good and can be improved by using the accentric factor.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.85

A 200-L rigid tank contains propane at 9 MPa, 280°C. The propane is then allowed to cool to 50°C as heat is transferred with the surroundings. Determine the quality at the final state and the mass of liquid in the tank, using the generalized compressibility chart, Fig. D.1.

Propane C_3H_8: $V = 0.2\ m^3$, $P_1 = 9$ MPa, $T_1 = 280^oC = 553.2$ K

cool to $T_2 = 50\ ^oC = 323.2$ K

From Table A.2: $T_c = 369.8$ K, $P_c = 4.25$ MPa

$P_{r1} = \frac{9}{4.25} = 2.118$, $T_{r1} = \frac{553.2}{369.8} = 1.496$ From Fig. D.1: $Z_1 = 0.825$

$$v_2 = v_1 = \frac{Z_1 RT_1}{P_1} = \frac{0.825 \times 0.188\ 55 \times 553.2}{9\ 000} = 0.00956\ m^3/kg$$

From Fig. D.1 at $T_{r2} = 0.874$,

$P_{G2} = 0.45 \times 4250 = 1912$ kPa

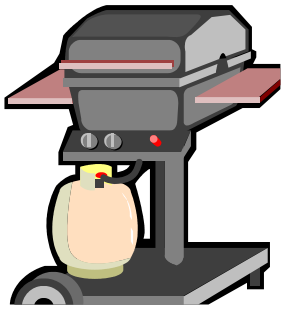
$v_{G2} = 0.71 \times 0.188\ 55 \times 323.2/1912 = 0.02263\ m^3/kg$

$v_{F2} = 0.075 \times 0.188\ 55 \times 323.2/1912 = 0.00239\ m^3/kg$

$0.00956 = 0.002\ 39 + x_2(0.02263 - 0.00239)$ => $x_2 =$ **0.354**

$m_{LIQ\ 2} = (1\text{-}0.354) \times 0.2/0.00956 =$ **13.51 kg**

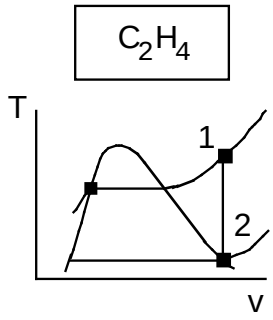
These tanks contain liquid propane.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.86

A rigid tank contains 5 kg of ethylene at 3 MPa, 30°C. It is cooled until the ethylene reaches the saturated vapor curve. What is the final temperature?



V = const m = 5 kg

P_1 = 3 MPa T_1 = 30 °C = 303.2 K

cool to x_2 = 1.0

$$P_{r1} = \frac{3}{5.04} = 0.595, \quad T_{r1} = \frac{303.2}{282.4} = 1.074$$

Fig. D.1: Z_1 = 0.82

Final state: x = 1, $v_2 = v_1$

Pv = ZRT so take the ratio between the two states

$$P_{r2} = P_{r1}\frac{Z_2 T_{r2}}{Z_1 T_{r1}} = 0.595\,\frac{Z_{G2} T_{r2}}{0.82 \times 1.074} = 0.6756\, Z_{G2} T_{r2}$$

Trial & error, Table D.4 may be easier to use than Fig. D.1:

T_{r2}	Z_{G2}	P_{r2}	$P_{r2\ CALC}$		
0.866	0.72	0.42	0.421	~ OK	=> T_2 = **244.6 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.87

The new refrigerant R-152a is used in a refrigerator with an evaporator temperature of –20°C and a condensing temperature of 30°C. What are the high and low pressures in this cycle?

Since we do not have the printed tables for R-152a we will use generalized charts. The critical properties are: $T_c = 386.4$ K, $P_c = 4.52$ MPa.

Evaporator:

$$T_{r1} = T/T_c = (273.15 - 20)/386.4 = 0.655$$

Fig. D.1: $P_{G\,T1} = P_{r1\,sat}\, P_c = 0.06 \times 4.52 =$ **0.271 MPa**

Condenser:

$$T_{r2} = T/T_c = (273.15 + 30)/386.4 = 0.785$$

Fig. D.1: $P_{G\,T2} = P_{r2\,sat}\, P_c = 0.22 \times 4.52 =$ **0.994 MPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.88

A 4-m^3 storage tank contains ethane gas at 10 MPa, 100^{o}C. Use Lee-Kesler EOS and find the mass of the ethane.

The Lee-Kesler EOS is shown as the generalized charts.

Table A.2: T_c = 305.4 K, P_c = 4.88 MPa, Table A.5: R = 0.2765 kJ/kg-K
The reduced properties are:

$$P_{r1} = \frac{10}{4.88} = 2.05, \quad T_{r1} = \frac{373.15}{305.4} = 1.22 \quad \Rightarrow \quad \text{Fig. D.1:} \quad Z = 0.56$$

$$m = \frac{PV}{ZRT} = \frac{10\,000 \times 4}{0.56 \times 0.2765 \times 373.15} = \mathbf{692.3\ kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.89

The ethane gas in the storage tank from the previous problem is cooled to 0^{o}C. Find the new pressure.

The new final state is given by: $(T_2, v_2 = v_1)$ $\quad T_{r2} = \dfrac{273.15}{305.4} = 0.8944$

Since Z and P are unknown this becomes trial and error solution.

$$P_2 / Z_2 = mRT_2 /V = 692.3 \times 0.2765 \times 273.15 /4 = 13071.7 \text{ kPa}$$

Assume it is saturated $\quad P_{r2} = 0.53$ (see Fig. D.1), $Z_g = 0.67$, $Z_f = 0.09$

$P_2 = 0.53 \times 4880 = 2586$ kPa and

$Z_2 = P_2 / 13071.7 = 0.198$ (two phase OK)

Ans.: $P_2 =$ **2586 kPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.90

Use CATT3 to solve the previous two problems when the acentric factor is used to improve the accuracy.

Problem 12.88:
The Lee-Kesler EOS is shown as the generalized charts.
Table A.2: $T_c = 305.4$ K, $P_c = 4.88$ MPa, Table A.5: R = 0.2765 kJ/kg-K
Table D.4: $\omega = 0.099$
The reduced properties are:

$$P_{r1} = \frac{10}{4.88} = 2.05, \quad T_{r1} = \frac{373.15}{305.4} = 1.22 \quad \Rightarrow \quad \text{CATT3:} \quad Z = 0.605$$

$$m = \frac{PV}{ZRT} = \frac{10\,000 \times 4}{0.605 \times 0.2765 \times 373.15} = \mathbf{640.8\ kg}$$

Problem 12.89:

The new final state is given by: $(T_2, v_2 = v_1)$ $\qquad T_{r2} = \frac{273.15}{305.4} = 0.8944$

Since Z and P are unknown this becomes trial and error solution.

$$P_2 / Z_2 = mRT_2 / V = 640.8 \times 0.2765 \times 273.15 / 4 = 12099.3 \text{ kPa}$$

Assume it is saturated vapor $P_{r2} = 0.483$ (CATT3), $Z_g = 0.69$, $Z_f = 0.078$

$P_2 = 0.483 \times 4880 = 2357$ kPa and

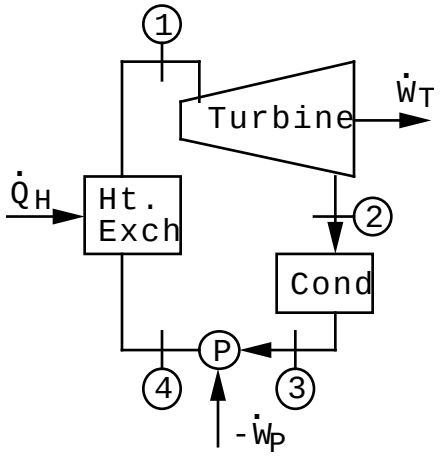
$Z_2 = P_2 / 12\,099.3 = 0.1948$ (two phase OK)

Ans.: $P_2 =$ **2357 kPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.91

A geothermal power plant uses butane as saturated vapor 80°C into the turbine and the condenser operates at 30°C. Find the reversible specific turbine work.



C_4H_{10} cycle

$T_1 = 80\ ^oC,\ x_1 = 1.0\ ;\ T_3 = 30^oC,\ x_3 = 0.0$

$$T_{r1} = \frac{353.2}{425.2} = 0.831$$

From D.1, D.2 and D.3:

$$P_1 = 0.325 \times 3800 = 1235 \text{ kPa}$$

$$(h_1^* - h_1) = 0.143\ 04 \times 425.2 \times 0.56 = 34.1$$

$$(s_1^* - s_1) = 0.143\ 04 \times 0.475 = 0.0680$$

$$T_{r3} = \frac{303.2}{425.2} = 0.713$$

From D.1, D.2 and D.3: $P_3 = 0.113 \times 3800 = 429$ kPa

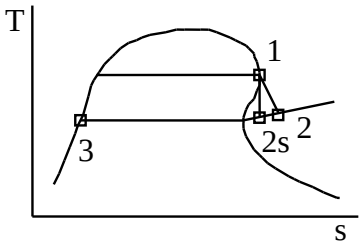
sat. liq.: $(h^* - h_f) = RT_c \times 4.81 = 292.5$; $(s^* - s_f) = R \times 6.64 = 0.950$

sat. vap.: $(h^* - h_g) = RT_c \times 0.235 = 14.3$; $(s^* - s_g) = R \times 0.22 = 0.031$

Because of the combination of properties of C_4H_{10} (particularly the large C_{p0}/R), s_1 is larger than s_g at T_3. To demonstrate,

$$(s_1^* - s_{g3}^*) = 1.7164 \ln \frac{353.2}{303.2} - 0.143\ 04 \ln \frac{1235}{429} = 0.1107$$

$$(s_1 - s_{g3}) = -0.0680 + 0.1107 + 0.031 = +0.0737 \text{ kJ/kg K}$$



so that T_{2S} will be $> T_3$, as shown in the T-s diagram. A number of other heavy hydrocarbons also exhibit this behavior.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Solution 12.91 Continued.

Assume $T_{2S} = 315$ K, => $T_{r2S} = 315 / 425.2 = 0.741$

From D.2 and D.3:

$$(h^*_{2S} - h_{2S}) = RT_c \times 0.21 = 12.8 \quad \text{and} \quad (s^*_{2S} - s_{2S}) = R \times 0.19 = 0.027$$

$$(s^*_1 - s^*_{2S}) = 1.7164 \ln \frac{353.2}{315} - 0.143\,04 \ln \frac{1235}{429} = +0.0453$$

$$(s_1 - s_{2S}) = -0.0680 + 0.0453 + 0.027 \approx 0$$

$$\Rightarrow T_{2S} = 315 \text{ K}$$

$$(h^*_1 - h^*_{2S}) = 1.7164(353.2-315) = 65.6$$

$$w_{ST} = h_1 - h_{2S} = -34.1 + 65.6 + 12.8 = \mathbf{44.3\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.92

Consider the following EOS, expressed in terms of reduced pressure and temperature:

$$Z = 1 + \frac{P_r}{14\,T_r}\left(1 - \frac{6}{T_r^2}\right)$$

What does this equation predict for enthalpy departure from the ideal gas value at the state $P_r = 0.4$, $T_r = 0.9$? What is it from the generalized charts?

$$Z = \frac{Pv}{RT} = 1 + \frac{P_r}{14\,T_r}\left(1 - \frac{6}{T_r^2}\right)$$

$$v = \frac{RT}{P} + \frac{RT_c}{14P_c}\left(1 - \frac{6T_c^2}{T^2}\right); \quad \left(\frac{\partial v}{\partial T}\right)_p = \frac{R}{P} + \frac{12RT_c^3}{14P_cT^3}$$

$$v - T\left(\frac{\partial v}{\partial T}\right)_p = \frac{RT_c}{14P_c} - \frac{18RT_c^3}{14P_cT^2}$$

Now Eq.12.27 is integrated with limits similar to Eq.12.62

$$h - h^* = \int_0^P \left[v - T\left(\frac{\partial v}{\partial T}\right)_p\right] dP = \frac{RT_c}{14}\left(1 - \frac{18}{T_r^2}\right) P_r = \mathbf{-0.606\ RT_c}$$

Evaluate at $P_r = 0.4$, $T_r = 0.9$ from Fig. D2 to get

$$h - h^* = -(h^* - h) \approx -0.6\ RT_c$$

This result matched with in the accuracy the figure can be read.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.93

Consider the following equation of state, expressed in terms of reduced pressure and temperature:

$$Z = 1 + \frac{P_r}{14\,T_r}\left(1 - \frac{6}{T_r^2}\right)$$

What does this equation predict for entropy departure from the ideal gas value at the state $P_r = 0.4$, $T_r = 0.9$?

The entropy departure is the change in s for a real gas minus the change in s for an ideal gas, so from Eq.12.32 and eq.6.14 we get

$$d(s - s^*) = C_p\frac{dT}{T} - \left(\frac{\partial v}{\partial T}\right)_p dP - \left[\, C_p\frac{dT}{T} - \frac{R}{P}\,dP\right] = \left[\frac{R}{P} - \left(\frac{\partial v}{\partial T}\right)_p\right] dP$$

Solve now for v from the compressibility factor (Z = Pv/RT) to get

$$Z = \frac{Pv}{RT} = 1 + \frac{P_r}{14\,T_r}\left(1 - \frac{6}{T_r^2}\right)$$

$$v = \frac{RT}{P} + \frac{RT_c}{14P_c}\left(1 - \frac{6T_c^2}{T^2}\right); \quad \left(\frac{\partial v}{\partial T}\right)_p = \frac{R}{P} + \frac{12RT_c^3}{14P_cT^3}$$

$$s - s^* = \int_0^P \left[\frac{R}{P} - \left(\frac{\partial v}{\partial T}\right)_p\right] dP = \int_0^P \left[- \frac{12RT_c^3}{14P_cT^3}\right] dP = -\frac{6}{7}\,R\,\frac{P_r}{T_r^3}$$

Evaluate at $P_r = 0.4$, $T_r = 0.9$ to get

$$s - s^* = -\mathbf{0.4703\ R}$$

12.94

A very low temperature refrigerator uses neon. From the compressor the neon at 1.5 MPa, 80 K goes through the condenser and comes out at saturated liquid 40 K. Find the specific heat transfer using generalized charts.

State 1: 80 K, 1.5 MPa : $T_{r1} = \frac{80}{44.4} = 1.802$, $P_{r1} = \frac{1.5}{2.76} = 0.543$

State 2: 40 K, x = 0: $T_{r2} = 0.90$, $P_{r2} = 0.532$

The enthalpy departure chart Fig. D.2:

$$(h^* - h)_1 = 0.22\ RT_c\ , \qquad (h^* - h)_2 = 4.10\ RT_c$$

$$h_2^* - h_1^* = 1.03\ (40 - 80) = -41.2\ \text{kJ/kg}$$

$$h_2 - h_1 = h_2^* - h_1^* - (h^* - h)_2 + (h^* - h)_1$$

$$= -41.2 + 0.412 \times 44.4\ (-4.10 + 0.22) = -112.2\ \text{kJ/kg}$$

$$q = h_2 - h_1 = \mathbf{-112.2\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.95

Repeat the previous problem using CATT3 software for the neon properties.

From CATT3: $h_1 = 138.3$ kJ/kg, $h_2 = 30.24$ kJ/kg (P = 1.46 MPa)

$$q = h_2 - h_1 = 30.24 - 138.3 = \mathbf{-108.1\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.96

A piston/cylinder contains 5 kg of butane gas at 500 K, 5 MPa. The butane expands in a reversible polytropic process to 3 MPa, 460 K. Determine the polytropic exponent n and the work done during the process.

C_4H_{10} m = 5 kg T_1 = 500 K P_1 = 5 MPa

Rev. polytropic process: $P_1V_1^n = P_2V_2^n$

$T_{r1} = \frac{500}{425.2} = 1.176$, $P_{r1} = \frac{5}{3.8} = 1.316$ From Fig. D.1: $Z_1 = 0.68$

$T_{r2} = \frac{460}{425.2} = 1.082$, $P_{r2} = \frac{3}{3.8} = 0.789$ From Fig. D.1: $Z_2 = 0.74$

$$V_1 = \frac{mZRT}{P} = \frac{5 \times 0.68 \times 0.1430 \times 500}{5000} = 0.0486 \text{ m}^3$$

$$V_2 = \frac{mZRT}{P} = \frac{5 \times 0.74 \times 0.1430 \times 460}{3000} = 0.0811 \text{ m}^3$$

Solve for the polytropic exponent, n, as

$$n = \ln(P_1/P_2) \,/\, \ln(V_2/V_1) = \ln(\tfrac{5}{3}) / \ln(\tfrac{0.0811}{0.0486}) = \mathbf{0.9976}$$

$$_1W_2 = \int_1^2 PdV = \frac{P_2V_2 - P_1V_1}{1-n} = \frac{3000 \times 0.0811 - 5000 \times 0.0486}{1 - 0.9976} = \mathbf{125 \text{ kJ}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.97

Calculate the heat transfer during the process described in Problem 12.96.

From solution 12.96,

$V_1 = 0.0486\ m^3, \quad V_2 = 0.0811\ m^3, \quad {}_1W_2 = 125\ kJ$

$T_{r1} = \frac{500}{425.2} = 1.176, \quad P_{r1} = \frac{5}{3.8} = 1.316$ From Fig. D.1: $Z_1 = 0.68$

$T_{r2} = 1.082, \ P_{r2} = 0.789, \ T_2 = 460\ K$

From Fig. D.2: $(h^* - h)_1 = 1.30\ RT_C, \quad (h^* - h)_2 = 0.90\ RT_C$

$h_2^* - h_1^* = 1.716(460 - 500) = -83.1\ kJ/kg$

$h_2 - h_1 = -83.1 + \frac{8.3145 \times 425.2}{58.124}(-0.90 + 1.30) = -58.8\ kJ/kg$

$U_2 - U_1 = m(h_2 - h_1) - P_2V_2 + P_1V_1$

$= 5(-58.8) - 3000 \times 0.0811 + 5000 \times 0.0486 = -288.3\ kJ$

${}_1Q_2 = U_2 - U_1 + {}_1W_2 =$ **-174.3 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.98

An ordinary lighter is nearly full of liquid propane with a small amount of vapor, the volume is 5 cm^3, and temperature is 23°C. The propane is now discharged slowly such that heat transfer keeps the propane and valve flow at 23°C. Find the initial pressure and mass of propane and the total heat transfer to empty the lighter.

Propane C_3H_8 $\quad T_1 = 23^oC = 296.2$ K = constant, $\quad x_1 = 0.0$

$V_1 = 5\ cm^3 = 5\times10^{-6}\ m^3$, $\quad T_{r1} = 296.2/369.8 = 0.804$

From Figs. D.1 and D.2,

$P_1 = P_{G\,T1} = 0.25\times4.25 =$ **1.063 MPa**, $\quad Z_1 = 0.04$

$(h_1^* - h_1) = 0.188\ 55\times369.8\times4.51 = 314.5$

$$m_1 = \frac{P_1V_1}{Z_1RT_1} = \frac{1063\times5\times10^{-6}}{0.04\times0.188\ 55\times296.2} = \mathbf{0.00238\ kg}$$

State 2: Assume vapor at 100 kPa, 23°C ideal gas so no corrections

Therefore, m_2 much smaller than m_1 (~ 9.0×10^{-6} kg)

$$Q_{CV} = m_2u_2 - m_1u_1 + m_eh_e$$

$$= m_2h_2 - m_1h_1 - (P_2 - P_1)V + (m_1 - m_2)h_e$$

$$= m_2(h_2 - h_e) + m_1(h_e - h_1) - (P_2 - P_1)V$$

$(h_e - h_1) = 0 + 0 + 314.5$

$Q_{CV} = \approx 0 + 0.00238(314.5) - (100 - 1063)\times5\times10^{-6} =$ **0.753 kJ**

Actual lighters use butane and some propane.

12.100

Find the heat of evaporation, h_{fg}, for isobutane (T_c = 408.2 K, P_c = 3.65 MPa, M = 58.124) at 12.6°C from the generalized charts and compare to the values in the CATT3 computerized tables.

To read the charts we need the reduced temperature

$$T_{r1} = T/T_c = (12.6 + 273.15)/408.2 = 0.70$$

$$(h^* - h)_g = 0.2\ RT_c \ ; \quad (h^* - h)_f = 4.85\ RT_c$$

$$h_{fg} = h_g - h_f = -(h^* - h)_g - (h^* - h)_f = (-0.2 + 4.85)\ RT_c$$

$$= 4.65\ RT_c = 4.65 \times (8.3145/58.124) \times 408.2$$

$$= \mathbf{271.5\ kJ/kg}$$

CATT3: $h_{fg} = -25.62 + 368.7 = \mathbf{343\ kJ/kg}$

The generalized charts are not super accurate, some improvement can be done using the accentric factor.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.101

A cylinder contains ethylene, C_2H_4, at 1.536 MPa, –13°C. It is now compressed isothermally in a reversible process to 5.12 MPa. Find the specific work and heat transfer.

Ethylene C_2H_4 $P_1 = 1.536$ MPa , $T_2 = T_1 = -13^oC = 260.2$ K

$T_{r2} = T_{r1} = 260.2 / 282.4 = 0.921$, $P_{r1} = 1.536 / 5.04 = 0.305$

From D.1, D.2 and D.3: $Z_1 = 0.85$

$(h_1^* - h_1) = 0.2964 \times 282.4 \times 0.40 = 33.5$ and $(s_1^* - s_1) = 0.2964 \times 0.30 = 0.0889$

From D.1, D.2 and D.3: $Z_2 = 0.17$, $P_{r2} = 5.12/5.04 = 1.016$ (comp. liquid)

$(h_2^* - h_2) = 0.2964 \times 282.4 \times 4.0 = 334.8$ and $(s_2^* - s_2) = 0.2964 \times 3.6 = 1.067$

Ideal gas: $(h_2^* - h_1^*) = 0$ and $(s_2^* - s_1^*) = 0 - 0.2964 \ln \frac{5.12}{1.536} = -0.3568$

$_1q_2 = T(s_2 - s_1) = 260.2(-1.067 - 0.3568 + 0.0889) =$ **-347.3 kJ/kg**

$(h_2 - h_1) = -334.8 + 0 + 33.5 = -301.3$ kJ/kg

$(u_2 - u_1) = (h_2 - h_1) - RT(Z_2 - Z_1) = -301.3 - 0.2964 \times 260.2(0.17 - 0.85) = -248.9$

$_1w_2 = {}_1q_2 - (u_2 - u_1) = -347.3 + 248.9 =$ **-98.4 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.102

Saturated vapor R-410A at 30°C is throttled to 200 kPa in a steady flow process. Calculate the exit temperature assuming no changes in the kinetic energy, using the generalized charts, Fig. D.2 and the R-410A tables, Table B.4.

R-410A throttling process

Energy Eq.: $h_2 - h_1 = 0 = (h_2 - h_2^*) + (h_2^* - h_1^*) + (h_1^* - h_1)$

Generalized Chart, Fig. D.2, R = 8.31451/72.585 = 0.11455 kJ/kg-K

$$T_{r1} = \frac{303.2}{344.5} = 0.88 \quad => \quad (h_1^* - h_1) = 0.11455 \times 344.5\ (0.85) = 33.54 \text{ kJ/kg}$$

For C_{P0}, use h values from Table B.4 at low pressure.

$C_{P0} \approx (330.83 - 314.40) / (40 - 20) = 0.8215$ kJ/kg K

Substituting: $(h_2 - h_2^*) + 0.8215\ (T_2 - 30) + 33.54 = 0$

at $P_{r2} = 200/4900 = 0.041$

Assume $T_2 = -10^oC$ => $T_{r2} = 263.2/344.5 = 0.764$

$(h_2^* - h_2) = RT \times 0.1 = 0.11455 \times 344.5\ (0.1) = 3.95$

Substituting : $-3.95 + 0.8215\ (-10 - 30) + 33.54 = -3.27$

Assume $T_2 = -5^oC$ => $T_{r2} = 268.2/344.5 = 0.778$

$(h_2^* - h_2) = RT \times 0.1 = 0.11455 \times 344.5\ (0.1) = 3.95$

Substituting : $-3.95 + 0.8215\ (-5 - 30) + 33.54 = 0.84$

$\Rightarrow T_2 =$ **-6.0 ^oC**

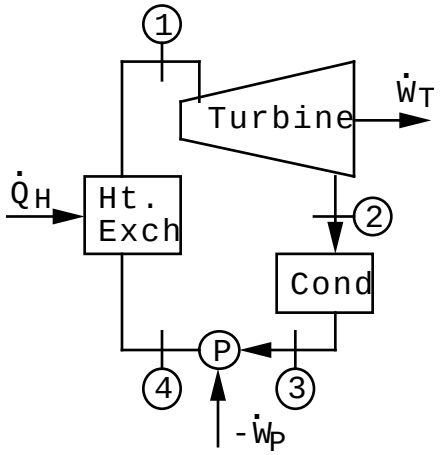
R-410A tables, B.4: at $T_1 = 30^oC$, $x_1 = 1.0$ => $h_1 = 284.16$ kJ/kg

$h_2 = h_1 = 284.16$, $P_2 = 0.2$ MPa => $T_2 =$ **-13.4 ^oC**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.103

Repeat Problem 12.91 using CATT3 and include the acentric factor for butane to improve the accuracy.



C_4H_{10} cycle

$T_1 = 80\ ^oC,\ x_1 = 1.0\ ;\ T_3 = 30^oC,\ x_3 = 0.0$

$$T_{r1} = \frac{353.2}{425.2} = 0.831$$

From CATT3 with $\omega = 0.199$:

$$P_1 = 0.2646 \times 3800 = 1005 \text{ kPa}$$

$$(h_1^* - h_1) = 0.1430 \times 425.2 \times 0.5685 = 34.6$$

$$(s_1^* - s_1) = 0.1430 \times 0.4996 = 0.0714$$

$$T_{r3} = \frac{303.2}{425.2} = 0.713$$

From CATT3 with $\omega = 0.199$: $P_3 = 0.07443 \times 3800 = 282.8$ kPa

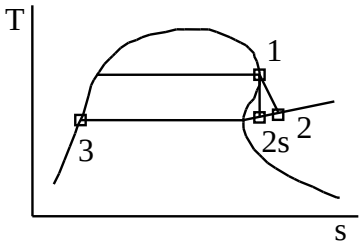
sat. liq.: $(h^* - h_f) = RT_c \times 6.048 = 367.74$; $(s^* - s_f) = R \times 8.399 = 1.201$

sat. vap.: $(h^* - h_g) = RT_c \times 0.202 = 12.28$; $(s^* - s_g) = R \times 0.201 = 0.0287$

Because of the combination of properties of C_4H_{10} (particularly the large C_{P0}/R), s_1 is larger than s_g at T_3. To demonstrate,

$$(s_1^* - s_{g3}^*) = 1.716 \ln \frac{353.2}{303.2} - 0.1430 \ln \frac{1005}{282.8} = 0.0806$$

$$(s_1 - s_{g3}) = -0.0714 + 0.0806 + 0.0287 = +0.0379 \text{ kJ/kg K}$$



so that T_{2S} will be $> T_3$, as shown in the T-s diagram. A number of other heavy hydrocarbons also exhibit this behavior.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Solution 12.103 continued.

Assume $T_{2S} = 315$ K, => $T_{r2S} = 315 / 425.2 = 0.741$

From CATT3:

$$(h^*_{2S} - h_{2S}) = RT_c \times 0.183 = 11.13 \quad \text{and} \quad (s^*_{2S} - s_{2S}) = R \times 0.1746 = 0.025$$

$$(s^*_1 - s^*_{2S}) = 1.716 \ln \frac{353.2}{315} - 0.1430 \ln \frac{1005}{282.8} = +0.01509$$

$$(s_1 - s_{2S}) = -0.0714 + 0.01509 + 0.025 = -0.031$$

Repeat at $T_{2S} = 310$ K to get $T_{r2S} = 0.729$,

$$(h^*_{2S} - h_{2S}) = RT_c \times 0.1907 = 11.595 \quad \text{and} \quad (s^*_{2S} - s_{2S}) = R \times 0.1853 = 0.0265$$

$$(s^*_1 - s^*_{2S}) = 1.716 \ln \frac{353.2}{310} - 0.1430 \ln \frac{1005}{282.8} = +0.04255$$

$$(s_1 - s_{2S}) = -0.0714 + 0.04255 + 0.0265 = -0.0023$$ very close to 0, OK

$$\Rightarrow T_{2S} = 310 \text{ K}$$

$$(h^*_1 - h^*_{2S}) = 1.716 \, (353.2 - 310) = 74.13$$

$$w_{ST} = h_1 - h_{2S} = -34.6 + 74.13 + 11.6 = \mathbf{51.1\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.104

A cylinder contains ethylene, C_2H_4, at 1.536 MPa, –13°C. It is now compressed in a reversible isobaric (constant *P*) process to saturated liquid. Find the specific work and heat transfer.

Ethylene C_2H_4 ; $P_1 = 1.536$ MPa = P_2 , $T_1 = -13^oC = 260.2$ K

State 2: saturated liquid, $x_2 = 0.0$

$$T_{r1} = \frac{260.2}{282.4} = 0.921 \quad P_{r1} = P_{r2} = \frac{1.536}{5.04} = 0.305$$

From Figs. D.1, D.2: $Z_1 = 0.85$, $(h_1^* - h_1)/RT_c = 0.40$

$$v_1 = \frac{Z_1 RT_1}{P_1} = \frac{0.85 \times 0.29637 \times 260.2}{1536} = 0.042675$$

$$(h_1^* - h_1) = 0.296\,37 \times 282.4 \times 0.40 = 33.5$$

From Figs. D.1, D.2: $T_2 = 0.824 \times 282.4 = 232.7$ K

$Z_2 = 0.05$, $(h_2^* - h_2)/RT_c = 4.42$

$$v_2 = \frac{Z_2 RT_2}{P_2} = \frac{0.05 \times 0.29637 \times 232.7}{1536} = 0.002245 \text{ m}^3/\text{kg}$$

$$(h_2^* - h_2) = 0.296\,37 \times 282.4 \times 4.42 = 369.9$$

$$(h_2^* - h_1^*) = C_{P0}(T_2 - T_1) = 1.5482(232.7 - 260.2) = -42.6$$

$$w_{12} = \int P dv = P(v_2 - v_1) = 1536 \text{ kPa } (0.002\,245 - 0.042\,675) \text{ m}^3/\text{kg}$$

$$= \mathbf{-62.1 \text{ kJ/kg}}$$

$$q_{12} = (u_2 - u_1) + w_{12} = (h_2 - h_1) = -369.9 - 42.6 + 33.5$$

$$= \mathbf{-379 \text{ kJ/kg}}$$

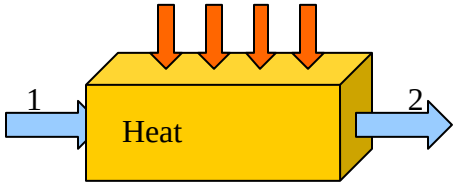
12.105

Refrigerant-123, dichlorotrifluoroethane, which is currently under development as a potential replacement for environmentally hazardous refrigerants, undergoes an isothermal steady flow process in which the R-123 enters a heat exchanger as saturated liquid at 40°C and exits at 100 kPa. Calculate the heat transfer per kilogram of R-123, using the generalized charts, Fig. D.2

R-123: M = 152.93, T_C = 456.9 K, P_C = 3.67 MPa



$T_1 = T_2 = 40\ ^oC$, $x_1 = 0$
$P_2 = 100$ kPa

$T_{r1} = T_{r2} = 313.2/456.9 = 0.685$, $P_{r2} = 0.1/3.67 = 0.027$

From Fig. D.2: $P_{r1} = 0.084$, $(h^* - h)_1/RT_C = 4.9$

From D.1: saturated $P_1 = 0.084 \times 3670 = 308$ kPa

$P_2 < P_1$ with no work done, so process is irreversibel.

Energy Eq.: $q + h_1 = h_2$, Entropy Eq.: $s_1 + \int dq/T + s_{gen} = s_2$, $s_{gen} > 0$

From Fig. D.2: $(h^* - h)_2/RT_C = 0.056$

$q = h_2 - h_1 = 8.3145 \times 456.9 \left[-0.056 + 0 + 4.90\right]/152.93 =$ **120.4 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.106

Carbon dioxide collected from a fermentation process at 5°C, 100 kPa should be brought to 243 K, 4 MPa in a steady flow process. Find the minimum amount of work required and the heat transfer. What devices are needed to accomplish this change of state?

$$T_{ri} = \frac{278.2}{304.1} = 0.915, \quad P_{ri} = \frac{100}{7380} = 0.0136$$

From D.2 and D.3 : $(h^* - h)_{ri}/RT_C = 0.02, \quad (s^* - s)_{ri}/R = 0.01$

$$T_{re} = \frac{243}{304.1} = 0.80, \quad P_{re} = \frac{4}{7.38} = 0.542$$

From D.2 and D.3: $(h^* - h)_{re}/RT_C = 4.5 , \quad (s^* - s)_{re}/R = 4.74$

$$(h_i - h_e) = -(h_i^* - h_i) + (h_i^* - h_e^*) + (h_e^* - h_e)$$

$$= -0.188\ 92 \times 304.1 \times 0.01 + 0.8418(278.2 - 243)$$

$$+ 0.188\ 92 \times 304.1 \times 4.5 = 287.6 \text{ kJ/kg}$$

$$(s_i - s_e) = -(s_i^* - s_i) + (s_i^* - s_e^*) + (s_e^* - s_e)$$

$$= -0.188\ 92 \times 0.01 + 0.8418 \ln(278.2/243)$$

$$- 0.188\ 92 \ln(0.1/4) + 0.188\ 92 \times 4.74 = 1.7044 \text{ kJ/kg K}$$

$$w^{rev} = (h_i - h_e) - T_0(s_i - s_e) = 287.6 - 278.2(1.7044) = \mathbf{-186.6\ kJ/kg}$$

$$q^{rev} = (h_e - h_i) + w^{rev} = -287.6 - 186.6 = \mathbf{-474.2\ kJ/kg}$$

We need a compressor to bring the pressure up and a cooler to bring the temperature down. Cooling it before compression and intercooling between stages in the compressor lowers the compressor work. In an actual set-up we require more work than the above reversible limit.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.107

Determine how accurate the generalized chart is for the carbon dioxide process in Problem 12.106 by using the CATT3 software for the carbon dioxide properties.

From the CATT3 software:

Inlet superheated vapor $h_i = 376.1$ kJ/kg and $s_i = 2.015$ kJ/kg-K

Exit compressed liquid $h_e = 20.21$ kJ/kg and $s_e = 0.07349$ kJ/kg-K

$$w^{rev} = (h_i - h_e) - T_0(s_i - s_e) = 376.1 - 20.21 - 278.2\,(2.015 - 0.07349)$$

$$= \mathbf{-184.1\ kJ/kg}$$

$$q^{rev} = (h_e - h_i) + w^{rev} = (20.21 - 376.1) - 184.1 = \mathbf{-540\ kJ/kg}$$

The work is very accurate but the heat transfer a little less so. The enthalpy and entropy differences are both under-estimated by the generalized charts.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.108

A geothermal power plant on the Raft River uses isobutane as the working fluid. The fluid enters the reversible adiabatic turbine at 160°C, 5.475 MPa, and the condenser exit condition is saturated liquid at 33°C. Isobutane has the properties T_c= 408.14 K, P_c= 3.65 MPa, C_{P0}= 1.664 kJ/kg K and ratio of specific heats k = 1.094 with a molecular weight as 58.124. Find the specific turbine work and the specific pump work.

Turbine inlet: $T_1 = 160^oC$, $P_1 = 5.475$ MPa

Condenser exit: $T_3 = 33^oC$, $x_3 = 0.0$, $T_{r3} = 306.2 / 408.1 = 0.75$

From Fig. D.1:

$P_{r3} = 0.16$, $Z_3 = 0.03$ => $P_2 = P_3 = 0.16 \times 3.65 = 0.584$ MPa

$T_{r1} = 433.2 / 408.1 = 1.061$, $P_{r1} = 5.475 / 3.65 = 1.50$

From Fig. D.2 & D.3:

$(h_1^* - h_1) = 0.143\ 05 \times 408.1 \times 2.84 = 165.8$

$(s_1^* - s_1) = 0.143\ 05 \times 2.15 = 0.3076$

$$(s_2^* - s_1^*) = 1.664 \ln \frac{306.2}{433.2} - 0.143\ 05 \ln \frac{0.584}{5.475} = -0.2572$$

$(s_2^* - s_2) = (s_2^* - s_{F2}) - x_2\, s_{FG2}$

$= 0.143\ 05 \times 6.12 - x_2 \times 0.143\ 05(6.12-0.29) = 0.8755 - x_2 \times 0.8340$

$(s_2 - s_1) = 0 = -0.8755 + x_2 \times 0.8340 - 0.2572 + 0.3076$ => $x_2 = 0.99$

$(h_2^* - h_1^*) = C_{P0}(T_2 - T_1) = 1.664(306.2 - 433.2) = -211.3$

From Fig. D.2:,

$(h_2^* - h_2) = (h_2^* - h_{F2}) - x_2 h_{FG2} = 0.143\ 05 \times 408.1[4.69-0.99(4.69-0.32)]$

$= 273.8 - 0.99 \times 255.1 = 21.3$

Turbine: $w_T = (h_1 - h_2) = -165.8 + 211.3 + 21.3 =$ **66.8 kJ/kg**

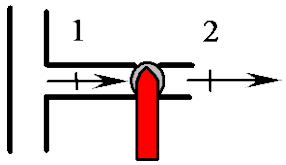
Pump: $$v_{F3} = \frac{Z_{F3} R T_3}{P_3} = \frac{0.03 \times 0.143\ 05 \times 306.2}{584} = 0.00225$$

$w_P = -\int v\, dP \approx v_{F3}(P_4 - P_3) = -0.00225\ (5475-584) =$ **-11.0 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.109

A flow of oxygen at 230 K, 5 MPa is throttled to 100 kPa in a steady flow process. Find the exit temperature and the entropy generation.



Process: Throttling

Small surface area: $\dot{Q} = 0$;

No shaft: $\dot{W} = 0$

Irreversible: $\dot{S}_{gen} > 0$

We will solve the problem using generalized charts.

$$T_{ri} = \frac{230}{154.6} = 1.488, \quad P_{ri} = \frac{5}{5.04} = 0.992, \quad P_{re} = \frac{0.1}{5.04} = 0.02$$

From D.2: $(h_i^* - h_i) = RT_c\,\Delta h = 0.2598 \times 154.6 \times 0.50 = 20.1$ kJ/kg

Energy Eq.: $(h_e - h_i) = 0 = -(h_e^* - h_e) + (h_e^* - h_i^*) + (h_i^* - h_i)$

Assume $T_e = 208$ K , $T_{re} = 1.345$:

$(h_e^* - h_i^*) = C_p\,(T_e - T_i) = 0.922\,(208 - 230) = -20.3$ kJ/kg

From D.2: $(h_e^* - h_e) = RT_c\,\Delta h = 0.2598 \times 154.6 \times 0.01 = 0.4$

Check first law $(h_e - h_i) = -0.4 - 20.3 + 20.1 \approx 0$ OK => $T_e =$ **208 K**

From D.3,

$(s_i^* - s_i) = 0.2598 \times 0.25 = 0.0649$ and $(s_e^* - s_e) = 0.2598 \times 0.01 = 0.0026$

$$(s_e^* - s_i^*) = 0.9216 \ln \frac{208}{230} - 0.2598 \ln \frac{0.1}{5} = 0.9238 \text{ kJ/kg K}$$

$s_{gen} = (s_e - s_i) = -0.0026 + 0.9238 + 0.0649 =$ **0.9861 kJ/kg K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.110

An uninsulated piston/cylinder contains propene, C_3H_6, at ambient temperature, 19°C, with a quality of 50% and a volume of 10 L. The propene now expands very slowly until the pressure in the cylinder drops to 460 kPa. Calculate the mass of propene, the work, and heat transfer for this process.

Propene C_3H_6: $T_1 = 19^oC = 292.2$ K, $x_1 = 0.50$, $V_1 = 10$ L

From Fig. D.1: $T_{r1} = 292.2/364.9 = 0.80$,

$P_{r1} = P_{r\,sat} = 0.25$, $P_1 = 0.25 \times 4.6 = 1.15$ MPa

From D.1: $Z_1 = 0.5 \times 0.04 + 0.5 \times 0.805 = 0.4225$

$$m = \frac{P_1V_1}{Z_1RT_1} = \frac{1150\times0.010}{0.4225\times0.197\,58\times292.2} = \mathbf{0.471\ kg}$$

Assume reversible and isothermal process (slow, no friction, not insulated)

$${}_1Q_2 = m(u_2-u_1) + {}_1W_2$$

$${}_1W_2 = \int_1^2 PdV \text{ (cannot integrate)}; \qquad {}_1Q_2 = \int_1^2 TdS = Tm(s_2-s_1)$$

From Figs. D.2 and D.3:

$$h_1^* - h_1 = 0.19758 \times 364.9(0.5 \times 4.51 + 0.5 \times 0.46) = 179.2 \text{ kJ/kg}$$

$$(s_1^* - s_1) = 0.197\,58\,(0.5 \times 5.46 + 0.5 \times 0.39) = 0.5779 \text{ kJ/kg K}$$

The ideal gas change in h and s are

$$(h_2^* - h_1^*) = 0 \text{ and } \qquad (s_2^* - s_1^*) = 0 - 0.197\,58 \ln\frac{460}{1161} = +\,0.1829 \text{ kJ/kg K}$$

At $T_{r2} = 0.80$, $P_{r2} = 0.10$, from D.1, D.2 and D.3, $Z_2 = 0.93$

$$(h_2^* - h_2) = 0.197\,58 \times 364.9 \times 0.16 = 11.5 \text{ kJ/kg}$$

$$(s_2^* - s_2) = 0.197\,58 \times 0.13 = 0.0257 \text{ kJ/kg K}$$

Now we can do the change in s and h from state 1 to state 2

$$(s_2 - s_1) = -(s_2^* - s_2) + (s_2^* - s_1^*) + (s_1^* - s_1)$$

$$= -0.0257 + 0.1829 + 0.5779 = 0.7351 \text{ kJ/kg K}$$

$$(h_2 - h_1) = -(h_2^* - h_2) + (h_2^* - h_1^*) + h_1^* - h_1$$

$$= -11.5 + 0 + 179.2 = 167.7 \text{ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Solution 12.110 continued.

The heat transfer is found from the second law

$${}_1q_2 = 292.2 \times 0.7351 = 214.8 \text{ kJ/kg} \quad \Rightarrow \quad {}_1Q_2 = m\ {}_1q_2 = \mathbf{101.2\ kJ}$$

We need the internal energy in the energy equation

$$u_2 - u_1 = (h_2 - h_1) + RT(Z_1 - Z_2) = 167.7 + 0.197\,58 \times 292.2\ (0.4225 - 0.93)$$

$$= 138.4 \text{ kJ/kg}$$

$${}_1w_2 = {}_1q_2 - (u_2 - u_1) = 214.8 - 138.4 = 76.4 \text{ kJ/kg}$$

$${}_1W_2 = m\ {}_1w_2 = \mathbf{36.0\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.111

An alternative energy power plant has carbon dioxide at 6 MPa, 100^{o}C flowing into a turbine with an exit as saturated vapor at 1 MPa. Find the specific turbine work using generalized charts and repeat using Table B.3.

From Table A.5: $R = 0.1889$ kJ/kgK, $C_P = 0.842$ kJ/kg

From Table A.2: $T_C = 304.1$ K, $P_C = 7.38$ MPa

$$P_{ri} = \frac{6}{7.38} = 0.813, \quad T_{ri} = \frac{373.2}{304.1} = 1.227 \quad \Rightarrow \quad \Delta \tilde{h} = 0.70$$

From D.2 and D.3,

$$(h_i^* - h_i) = RT_C \times \Delta \tilde{h} = 0.1889 \times 304.1 \times 0.70 = 46.8 \text{ kJ/kg};$$

$$P_{re} = \frac{1}{7.38} = 0.1355, \; x = 1 \; \text{so} \; T_{re} = 0.73, \; T_e = 0.73 \times 304.1 = 222 \text{ K}$$

From D.2 and D.3,

$$(h_e^* - h_e) = RT_C \times \Delta \tilde{h} = 0.1889 \times 304.1 \times 0.25 = 46.8 \text{ kJ/kg};$$

$$w = h_i - h_e = h_i^* - h_e^* - (h_i^* - h_i) + (h_e^* - h_e)$$

$$= C_P(h_i - h_e) - RT_C(\Delta \tilde{h}_i - \Delta \tilde{h}_e)$$

$$= 0.842\,(373.15 - 222) - 0.1889 \times 0304.1\,(0.7 - 0.25)$$

$$= \mathbf{101.45 \text{ kJ/kg}}$$

From Table B.3

$$w = h_i - h_e = 421.69 - 322.39 = \mathbf{99.3 \text{ kJ/kg}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.112

A distributor of bottled propane, C_3H_8, needs to bring propane from 350 K, 100 kPa to saturated liquid at 290 K in a steady flow process. If this should be accomplished in a reversible setup given the surroundings at 300 K, find the ratio of the volume flow rates $\dot{V}_{in}/\dot{V}_{out}$, the heat transfer and the work involved in the process.

From Table A.2: $T_{ri} = \frac{350}{369.8} = 0.946$, $P_{ri} = \frac{0.1}{4.25} = 0.024$

From D.1, D.2 and D.3,

$Z_i = 0.99$

$(h_i^* - h_i) = 0.1886 \times 369.8 \times 0.03 = 2.1$ kJ/kg

$(s_i^* - s_i) = 0.1886 \times 0.02 = 0.0038$ kJ/kg K

$T_{re} = \frac{290}{369.8} = 0.784$, and $x = 0$

From D.1, D.2 and D.3,

$P_{re} = 0.22$, $P_e = 0.22 \times 4.25 = 0.935$ MPa and $Z_e = 0.036$

$(h_e^* - h_e) = 0.1886 \times 369.8 \times 4.57 = 318.6$ kJ/kg

$(s_e^* - s_e) = 0.1886 \times 5.66 = 1.0672$ kJ/kg K

$(h_e^* - h_i^*) = 1.679(290 - 350) = -100.8$ kJ/kg

$(s_e^* - s_i^*) = 1.679 \ln \frac{290}{350} - 0.1886 \ln \frac{0.935}{0.1} = -0.7373$ kJ/kg K

$(h_e - h_i) = -318.6 - 100.8 + 2.1 = -417.3$ kJ/kg

$(s_e - s_i) = -1.0672 - 0.7373 + 0.0038 = -1.8007$ kJ/kg K

$$\frac{\dot{V}_{in}}{\dot{V}_{out}} = \frac{Z_i T_i / P_i}{Z_e T_e / P_e} = \frac{0.99}{0.036} \times \frac{350}{290} \times \frac{0.935}{0.1} = \mathbf{310.3}$$

$w^{rev} = (h_i - h_e) - T_0(s_i - s_e) = 417.3 - 300(1.8007) = \mathbf{-122.9\ kJ/kg}$

$q^{rev} = (h_e - h_i) + w^{rev} = -417.3 - 122.9 = \mathbf{-540.2\ kJ/kg}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.113

An insulated cylinder fitted with a frictionless piston contains saturated-vapor carbon dioxide at 0°C, at which point the cylinder volume is 20 L. The external force on the piston is now slowly decreased, allowing the carbon dioxide to expand until the temperature reaches - 30°C. Calculate the work done by the CO_2 during this process.

CO_2: T_C = 304.1 K, P_C = 7.38 MPa, C_p = 0.842 kJ/kg-K, R = 0.1889 kJ/kg K

State 1: $T_1 = 0^oC$, sat. vap., $x_1 = 1.0$, V_1 = 20 L

$T_{r1} = 0.9$, $P_1 = P_{r1}P_C = 0.53 \times 7380 = 3911$ kPa, $Z_1 = Z_g = 0.67$

$(h_1^* - h_1)_g = 0.9\ RT_C$, $(s_1^* - s_1)_g/R = 0.72$, $m = \dfrac{P_1V_1}{Z_1RT_1} = 2.262$ kg

State 2: $T_2 = -30^oC$

$T_{r2} = 0.8$, $P_2 = P_{r2}P_C = 0.25 \times 7380 = 1845$ kPa

Entropy Eq.: $S_{gen} = m(s_2 - s_1) - {}_1Q_2/T$; ${}_1Q_2 = 0$, $S_{gen} = 0$

$s_2 - s_1 = (s_2 - s_2^*) + (s_2^* - s_1^*) + (s_1^* - s_1) = 0$

$s_2^* - s_1^* = C_P \ln \dfrac{T_2}{T_1} - R \ln \dfrac{P_2}{P_1} = 0.044$ kJ/kg-K, $s_1^* - s_1 = 0.136$ kJ/kg-K

$s_2^* - s_2 = 0.180$ kJ/kg K, $(s_2^* - s_2)_f = 5.46$ R, $(s_2^* - s_2)_g = 0.39$ R

$(s_2^* - s_2) = (1-x_2)(s_2^* - s_2)_f + x_2 (s_2^* - s_2)_g \rightarrow x_2 = 0.889$

Energy Eq.: ${}_1Q_2 = m(u_2 - u_1) + {}_1W_2$; ${}_1Q_2 = 0$, $u = h - Pv$

$Z_2 = (1 - x_2)Z_f + x_2Z_g = 0.111 \times 0.04 + 0.889 \times 0.81 = 0.725$;

$(h_2 - h_1) = (h_2 - h_2^*) + (h_2^* - h_1^*) + (h_1^* - h_1)$

$h_2^* - h_1^* = C_p(T_2 - T_1) = -25.3$ kJ/kg, $(h_1^* - h_1) = 51.7$ kJ/kg

$(h_2^* - h_2)_f = 4.51\ RT_C$, $(h_2^* - h_2)_g = 0.46\ RT_C$

$(h_2^* - h_2) = (1 - x_2)(h_2^* - h_2)_f + x_2 (h_2^* - h_2)_g = 52.2$ kJ/kg

$h_2 - h_1 = -52.2 - 25.3 + 51.7 = -25.8$ kJ/kg

$u_2 - u_1 = (h_2 - h_1) - Z_2RT_2 + Z_1RT_1 = -25.8 - 0.725 \times 0.18892 \times 243.2$

$+ 0.67 \times 0.18892 \times 273.2 = -24.5$ kJ/kg

${}_1W_2$ = **55.4 kJ**

12.114

A control mass of 10 kg butane gas initially at 80°C, 500 kPa, is compressed in a reversible isothermal process to one-fifth of its initial volume. What is the heat transfer in the process?

Butane C_4H_{10}: m = 10 kg, T_1 = 80 °C, P_1 = 500 kPa

Compressed, reversible T = const, to $V_2 = V_1/5$

$$T_{r1} = \frac{353.2}{425.2} = 0.831,\ P_{r1} = \frac{500}{3800} = 0.132$$

From D.1 and D.3: $Z_1 = 0.92$, $(s_1^* - s_1) = 0.143 \times 0.16 = 0.0230$

$$v_1 = \frac{Z_1 RT_1}{P_1} = \frac{0.92 \times 0.143 \times 353.2}{500} = 0.09296\ m^3/kg$$

State 2: $v_2 = v_1/5 = 0.01859\ m^3/kg$; $T_{r2} = T_{r1} = 0.831$

From D.1: $P_G = 0.325 \times 3800 = 1235$ kPa

sat. liq.: $Z_F = 0.05$, $(s^* - s_F) = R \times 5.08 = 0.7266$

sat. vap.: $Z_G = 0.775$, $(s^* - s_G) = R \times 0.475 = 0.0680$

Therefore

$$v_F = \frac{0.05 \times 0.143 \times 353.2}{1235} = 0.00205\ m^3/kg$$

$$v_G = \frac{0.775 \times 0.143 \times 353.2}{1235} = 0.0317\ m^3/kg$$

Since $v_F < v_2 < v_G \rightarrow x_2 = (v_2 - v_F)/(v_G - v_F) = 0.5578$

$$(s_2^* - s_2) = (1 - x_2)(s_2^* - s_{F2}) + x_2(s_2^* - s_{G2})$$

$$= 0.4422 \times 0.7266 + 0.5578 \times 0.0680 = 0.3592\ kJ/kg\ K$$

$$(s_2^* - s_1^*) = C_{P0} \ln (T_2/T_1) - R \ln (P_2/P_1) = 0 - 0.143 \ln \frac{1235}{500} = -0.1293$$

$$(s_2 - s_1) = -0.3592 - 0.1293 + 0.0230 = -0.4655\ kJ/kg\ K$$

$$_1Q_2 = Tm(s_2 - s_1) = 353.2 \times 10\ (-0.4655) = \mathbf{-1644\ kJ}$$

12.115

A line with a steady supply of octane, C_8H_{18}, is at 400°C, 3 MPa. What is your best estimate for the availability in a steady flow setup where changes in potential and kinetic energies may be neglected?

Availability of Octane at $T_i = 400\ ^oC$, $P_i = 3$ MPa

From Table A.5: $R = 0.07279$ kJ/kgK, $C_P = 1.711$ kJ/kg

From Table A.2: $T_C = 568.8$ K, $P_C = 2.49$ MPa

$$P_{ri} = \frac{3}{2.49} = 1.205, \quad T_{ri} = \frac{673.2}{568.8} = 1.184$$

From D.2 and D.3,

$$(h_i^* - h_i) = RT_C \times \Delta\tilde{h} = 0.072\ 79 \times 568.8 \times 1.13 = 46.8 \text{ kJ/kg};$$

$$(s_i^* - s_i) = R\ \Delta\tilde{s} = 0.072\ 79 \times 0.69 = 0.05 \text{ kJ/kgK}$$

This is relative to the dead ambient state, assume $T_0 = 298.2$ K, $P_0 = 100$ kPa

$$T_{r0} = \frac{298.2}{568.8} = 0.524\ , \quad P_{r0} = \frac{0.1}{2.49} = 0.040$$

From D.2 and D.3, The s correction is outside chart (extrapolate or use CATT3)

$$(h_0^* - h_0) = RT_C \times 5.4 = 223.6 \quad \text{and} \quad (s_0^* - s_0) = R \times 9 = 0.655 \text{ kJ/kgK}$$

$$(h_i^* - h_0^*) = C_P(T_i - T_0) = 1.711\ (673.2 - 298.2) = 641.7 \text{ kJ/kg}$$

$$(s_i^* - s_0^*) = 1.711 \times \ln\frac{673.2}{298.2} - 0.072\ 79 \times \ln\frac{3}{0.1} = 1.1459 \text{ kJ/kgK}$$

$$(h_i - h_0) = -46.8 + 641.7 + 223.6 = 818.5 \text{ kJ/kg}$$

$$(s_i - s_0) = -0.05 + 1.1459 + 0.655 = 1.7509 \text{ kJ/kgK}$$

$$\varphi_i = w^{rev} = (h_i - h_0) - T_0(s_i - s_0) = 818.5 - 298.2(1.7509) = \mathbf{296.5\ kJ/kg}$$

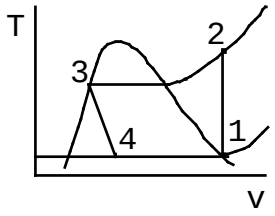
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.116

The environmentally safe refrigerant R-152a is to be evaluated as the working fluid for a heat pump system that will heat a house. It uses an evaporator temperature of –20°C and a condensing temperature of 30°C. Assume all processes are ideal and R-152a has a heat capacity of C_p = 0.996 kJ/kg K. Determine the cycle coefficient of performance.

Ideal Heat Pump $T_H = 30\ ^oC$

From A.2: M = 66.05, R = 0.125 88, $T_C = 386.4$ K, $P_C = 4.52$ MPa



$$T_{r3} = \frac{303.2}{386.4} = 0.785$$

$P_{r3} = P_{r2} = 0.22 \quad \Rightarrow \quad P_3 = P_2 = 994$ kPa

Sat.liq.: $h_3^* - h_3 = 4.56 \times RT_C = 221.8$

$T_1 = -20\ ^oC = 253.2$ K, $T_{r1} = 0.655$, $P_{r1} = 0.058 \rightarrow P_1 = 262$ kPa

$h_1^* - h_1 = 0.14 \times RT_C = 6.8$ and $s_1^* - s_1 = 0.14 \times R = 0.0176$

Assume $T_2 = 307$ K, $T_{r2} = 0.795$ given $P_{r2} = 0.22$

From D.2, D.3: $s_2^* - s_2 = 0.34 \times R = 0.0428$; $h_2^* - h_2 = 0.40 \times RT_c = 19.5$

$$s_2^* - s_1^* = 0.996 \ln \frac{307}{253.2} - 0.125\ 88 \ln \frac{994}{262} = 0.0241$$

$s_2 - s_1 = -0.0428 + 0.0241 + 0.0176 = -0.001 \approx 0$ OK

$\Rightarrow h_2 - h_1 = -19.5 + 0.996(307\text{-}253.2) + 6.8 = 40.9$

$h_2 - h_3 = -19.5 + 0.996(307\text{-}303.2) + 221.8 = 206.1$

$$\beta = \frac{q_H}{w_{IN}} = \frac{h_2 - h_3}{h_2 - h_1} = \frac{206.1}{40.9} = \mathbf{5.04}$$

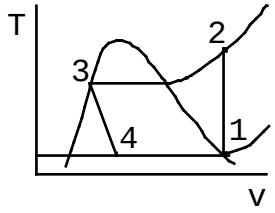
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.117

Rework the previous problem using an evaporator temperature of 0^{o}C.

Ideal Heat Pump $T_H = 30\ ^{o}$C

From A.2: M = 66.05, R = 0.125 88, $T_C = 386.4$ K, $P_C = 4.52$ MPa



$$T_{r3} = \frac{303.2}{386.4} = 0.785$$

$P_{r3} = P_{r2} = 0.22 \quad => \quad P_3 = P_2 = 994$ kPa

Sat.liq.: $h_3^* - h_3 = 4.56 \times RT_C = 221.8$

$T_1 = 0\ ^{o}$C = 273.2 K, $T_{r1} = 0.707$ => $P_{r1} = 0.106$, $P_1 = 479$ kPa

$h_1^* - h_1 = 0.22 \times RT_C = 10.7$ and $s_1^* - s_1 = 0.21 \times R = 0.0264$

Assume $T_2 = 305$ K, $T_{r2} = 0.789$

$s_2^* - s_2 = 0.35 \times R = 0.0441$ and $h_2^* - h_2 = 0.38 \times RT_C = 18.5$

$$s_2^* - s_1^* = 0.996 \ln\frac{305.0}{273.2} - 0.125\ 88 \ln\frac{994}{479} = 0.0178$$

$s_2 - s_1 = -0.0441 + 0.0178 + 0.0264 = 0.0001 \approx 0$ OK

$h_2 - h_1 = -18.5 + 0.996(305.0\text{-}273.2) + 10.7 = 23.9$

$h_2 - h_3 = -18.5 + 0.996(305.0\text{-}303.2) + 221.8 = 205.1$

$$\beta = \frac{h_2 - h_3}{h_2 - h_1} = \frac{205.1}{23.9} = \mathbf{8.58}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.118

An uninsulated compressor delivers ethylene, C_2H_4, to a pipe, $D = 10$ cm, at 10.24 MPa, 94°C and velocity 30 m/s. The ethylene enters the compressor at 6.4 MPa, 20.5°C and the work input required is 300 kJ/kg. Find the mass flow rate, the total heat transfer and entropy generation, assuming the surroundings are at 25°C.

$$T_{ri} = \frac{293.7}{282.4} = 1.040\ ,\ P_{ri} = \frac{6.4}{5.04} = 1.270$$

From D.2 and D.3,

$$(h_i^* - h_i) = 0.296\ 37 \times 282.4 \times 2.65 = 221.8\ \text{kJ/kg}$$

$$(s_i^* - s_i) = 0.296\ 37 \times 2.08 = 0.6164\ \text{kJ/kg K}$$

$$T_{re} = \frac{367.2}{282.4} = 1.30\ ,\ P_{re} = \frac{10.24}{5.04} = 2.032 \quad \Rightarrow \text{ From D.1: } \quad Z_e = 0.69$$

$$v_e = \frac{Z_e R T_e}{P_e} = \frac{0.69 \times 0.296\ 37 \times 367.2}{10\ 240} = 0.0073\ \text{m}^3/\text{kg}$$

$$A_e = \frac{\pi}{4} D_e^2 = 0.007\ 85\ \text{m}^2 \quad \Rightarrow \quad \dot{m} = \frac{A_e \mathbf{V}_e}{v_e} = \frac{0.007\ 85 \times 30}{0.0073} = \mathbf{32.26\ kg/s}$$

From D.2 and D.3,

$$(h_e^* - h_e) = 0.296\ 37 \times 282.4 \times 1.6 = 133.9\ \text{kJ/kg}$$

$$(s_e^* - s_e) = 0.296\ 37 \times 0.90 = 0.2667\ \text{kJ/kg K}$$

$$(h_e^* - h_i^*) = 1.5482(367.2 - 293.7) = 113.8$$

$$(s_e^* - s_i^*) = 1.5482 \ln \frac{367.2}{293.7} - 0.296\ 37 \ln \frac{10.24}{6.4} = 0.2065$$

$$(h_e - h_i) = -133.9 + 113.8 + 221.8 = 201.7\ \text{kJ/kg}$$

$$(s_e - s_i) = -0.2667 + 0.2065 + 0.6164 = 0.5562\ \text{kJ/kg K}$$

Energy Eq.:

$$q = (h_e - h_i) + KE_e + w = 201.7 + \frac{30^2}{2 \times 1000} - 300 = -97.9\ \text{kJ/kg}$$

$$\dot{Q}_{cv} = \dot{m} q = 32.26(-97.9) = \mathbf{-3158\ kW}$$

$$\dot{S}_{gen} = -\frac{\dot{Q}_{cv}}{T_o} + \dot{m}(s_e - s_i) = +\frac{3158}{298.2} + 32.26(0.5562) = \mathbf{28.53\ kW/K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.119

The new refrigerant fluid R-123 (see Table A.2) is used in a refrigeration system that operates in the ideal refrigeration cycle, except the compressor is neither reversible nor adiabatic. Saturated vapor at -26.5°C enters the compressor and superheated vapor exits at 65°C. Heat is rejected from the compressor as 1 kW, and the R-123 flow rate is 0.1 kg/s. Saturated liquid exits the condenser at 37.5°C. Specific heat for R-123 is C_P = 0.6 kJ/kg. Find the coefficient of performance.

R-123: T_C = 456.9 K, P_C = 3.67 MPa, M = 152.93 kg/kmol, R = 0.05438 kJ/kg K

State 1: $T_1 = -26.5^oC = 246.7$ K, sat vap., $x_1 = 1.0$

$T_{r1} = 0.54$, Fig D.1, $P_{r1} = 0.01$, $P_1 = P_{r1}P_C = 37$ kPa

Fig. D.2, $h_1^* - h_1 = 0.03\ RT_C = 0.8$ kJ/kg

State 2: $T_2 = 65^oC = 338.2$ K

State 3: $T_3 = 37.5^oC = 310.7$ K, sat. liq., $x_3 = 0$

$T_{r3} = 0.68$, Fig. D.1: $P_{r3} = 0.08$, $P_3 = P_{r3}P_C = 294$ kPa

$P_2 = P_3 = 294$ kPa, $P_{r2} = 0.080$, $T_{r2} = 0.74$,

Fig. D.2: $h_2^* - h_2 = 0.25\ RT_C = 6.2$ kJ/kg

$h_3^* - h_3 = 4.92\ RT_C = 122.2$ kJ/kg

State 4: $T_4 = T_1 = 246.7$ K, $h_4 = h_3$

Energy Eq. Evaporator: $q_L + h_4 = h_1 + w$; w = 0, $h_4 = h_3$

$q_L = h_1 - h_3 = (h_1 - h_1^*) + (h_1^* - h_3^*) + (h_3^* - h_3)$

$h_1^* - h_3^* = C_P(T_1 - T_3) = -38.4$ kJ/kg, $q_L = -0.8 - 38.4 + 122.2 = 83.0$ kJ/kg

Energy Eq. Compressor: $q + h_1 = h_2 + w_C$; $\dot{Q} = -1.0$ kW, $\dot{m} = 0.1$ kg/s

$w_C = h_1 - h_2 + q$; $h_1 - h_2 = (h_1 - h_1^*) + (h_1^* - h_2^*) + (h_2^* - h_2)$

$h_1^* - h_2^* = C_P(T_1 - T_2) = -54.9$ kJ/kg,

$w_c = -0.8 - 54.9 + 6.2 - 10.0 = -59.5$ kJ/kg

$\beta = q_L/w_c = 83.0/59.5 =$ **1.395**

12.120

An evacuated 100-L rigid tank is connected to a line flowing R-142b gas, chlorodifluoroethane, at 2 MPa, 100°C. The valve is opened, allowing the gas to flow into the tank for a period of time, and then it is closed. Eventually, the tank cools to ambient temperature, 20°C, at which point it contains 50% liquid, 50% vapor, by volume. Calculate the quality at the final state and the heat transfer for the process. The ideal-gas specific heat of R-142b is $C_p = 0.787$ kJ/kg K.

Rigid tank V = 100 L, $m_1 = 0$ Line: R-142b CH_3CClF_2

M = 100.495, $T_C = 410.3$ K, $P_C = 4.25$ MPa, $C_{P0} = 0.787$ kJ/kg K

$R = \bar{R}/M = 8.31451 / 100.495 = 0.082\ 73$ kJ/kg K

Line $P_i = 2$ MPa, $T_i = 100\ ^oC$, Flow in to $T_2 = T_0 = 20^oC$

$V_{LIQ\ 2} = V_{VAP\ 2} = 50$ L

Continuity: $m_i = m_2$; Energy: $Q_{CV} + m_i h_i = m_2 u_2 = m_2 h_2 - P_2 V$

From D.2 at i: $P_{ri} = 2 / 4.25 = 0.471$, $T_{ri} = 373.15 / 410.3 = 0.91$

$(h_i^* - h_i) = 0.082\ 73 \times 410.3 \times 0.72 = 24.4$

$(h_2^* - h_i^*) = C_{P0}(T_2 - T_i) = 0.787(20-100) = -63.0$

From D.2: $T_{r2} = \dfrac{293.2}{410.3} = 0.715$ => $P_2 = 0.115 \times 4250 = 489$ kPa

sat. liq.: $Z_F = 0.02$, $(h^* - h_F) = RT_C \times 4.85 = 164.6$

sat. vap.: $Z_G = 0.88$, $(h^* - h_G) = RT_C \times 0.25 = 8.5$

$$m_{LIQ\ 2} = \frac{P_2 V_{LIQ\ 2}}{Z_F R T_2} = \frac{489 \times 0.050}{0.02 \times 0.082\ 73 \times 293.2} = 50.4 \text{ kg}$$

$$m_{VAP\ 2} = \frac{P_2 V_{VAP\ 2}}{Z_G R T_2} = 1.15 \text{ kg}, \qquad m_2 = 51.55 \text{ kg}$$

$x_2 = m_{VAP\ 2}/m_2 = 0.0223$

$(h_2^* - h_2) = (1-x_2)(h_2^* - h_{F2}) + x_2(h_2^* - h_{G2}) = 0.9777 \times 164.6 + 0.0223 \times 8.5 = 161.1$

$Q_{CV} = m_2(h_2 - h_i) - P_2 V = 51.55(-161.1 - 63.0 + 24.4) - 489 \times 0.10$

= **-10 343 kJ**

12.121

A 2 kg mixture of 50% argon and 50% nitrogen by mole is in a tank at 2 MPa, 180 K. How large is the volume using a model of (a) ideal gas and (b) Kays rule with generalized compressibility charts.

a) Ideal gas mixture

Eq.11.5: $M_{mix} = \sum y_i M_i = 0.5 \times 39.948 + 0.5 \times 28.013 = 33.981$

$$V = \frac{m\bar{R}T}{M_{mix}P} = \frac{2 \times 8.3145 \times 180}{33.981 \times 2000} = \mathbf{0.044\ m^3}$$

b) Kay's rule Eq.12.84

$P_{c\ mix} = 0.5 \times 4.87 + 0.5 \times 3.39 = 4.13$ MPa

$T_{c\ mix} = 0.5 \times 150.8 + 0.5 \times 126.2 = 138.5$ K

Reduced properties: $P_r = \frac{2}{4.13} = 0.484, \quad T_r = \frac{180}{138.5} = 1.30$

Fig. D.1: $Z = 0.925$

$$V = Z\frac{m\bar{R}T}{M_{mix}P} = 0.925 \times 0.044 = \mathbf{0.0407\ m^3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.122

A 2 kg mixture of 50% argon and 50% nitrogen by mass is in a tank at 2 MPa, 180 K. How large is the volume using a model of (a) ideal gas and (b) van der Waals equation of state with a, b for a mixture?

a) Ideal gas mixture

Eq.11.15: $R_{mix} = \sum c_i R_i = 0.5 \times 0.2081 + 0.5 \times 0.2968 = 0.25245$ kJ/kg K

$$V = \frac{mR_{mix}T}{P} = \frac{2 \times 0.25245 \times 180}{2000} = \mathbf{0.0454\ m^3}$$

b) van der Waals equation of state. before we can do the parameters a, b for the mixture we need the individual component parameters.

$$a_{Ar} = \frac{27}{64}\frac{R^2T_c^2}{P_c} = \frac{27}{64}\frac{(0.2081 \times 150.8)^2}{4870} = 0.08531$$

$$a_{N2} = \frac{27}{64}\frac{R^2T_c^2}{P_c} = \frac{27}{64}\frac{(0.2968 \times 126.2)^2}{3390} = 0.17459$$

$$b_{Ar} = \frac{RT_c}{8P_c} = \frac{0.2081 \times 150.8}{8 \times 4870} = 0.000\ 805$$

$$b_{N2} = \frac{RT_c}{8P_c} = \frac{0.2968 \times 126.2}{8 \times 3390} = 0.001\ 381$$

Now the mixture parameters are from Eq.12.84

$$a_{mix} = \left(\sum c_i\, a_i^{1/2}\right)^2 = (0.5 \times \sqrt{0.08531} + 0.5 \times \sqrt{0.17459})^2 = 0.126$$

$$b_{mix} = \sum c_i\, b_i = 0.5 \times 0.000\ 805 + 0.5 \times 0.001\ 381 = 0.001\ 093$$

Using now Eq.12.52: $$P = \frac{RT}{v - b} - \frac{a}{v^2}$$

$$2000 = \frac{0.25245 \times 180}{v - 0.001\ 093} - \frac{0.126}{v^2}$$

By trial and error we find the specific volume, $v = 0.02097$ m^3/kg

$$V = mv = \mathbf{0.04194\ m^3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.123

R-410A is a 1:1 mass ratio mixture of R-32 and R-125. Find the specific volume at 20^{o}C, 1200 kPa using Kays rule and the generalized charts and compare to Table B.4

Kay's rule Eq.12.83

$P_{c\ mix} = 0.5 \times 5.78 + 0.5 \times 3.62 = 4.70$ MPa

$T_{c\ mix} = 0.5 \times 351.3 + 0.5 \times 339.2 = 345.25$ K

Reduced properties: $P_r = \dfrac{1.2}{4.70} = 0.255$, $T_r = \dfrac{293.15}{345.25} = 0.849$

Table A.5: R = 0.1145 kJ/kg-K or compute from mix

Fig. D.1: Z = 0.85

$v = ZRT/P = 0.85 \times 0.1145 \times 293.15 / 1200 =$ **0.0238 m^3/kg**

Table B.4: v = **0.02260 m^3/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.124

The R-410A in Problem 12.123 is flowing through a heat exchanger with an exit at 120°C, 1200 kPa. Find the specific heat transfer using Kays rule and the generalized charts and compare to solution using Table B.4

$R_{mix} = 0.5 \times 0.1598 + 0.5 \times 0.06927 = 0.1145$ kJ/kg-K,

$C_{P\,mix} = \sum c_i C_{P\,i} = 0.5 \times 0.822 + 0.5 \times 0.791 = 0.8065$ kJ/kg K

Kay's rule Eq.12.84

$P_{c\,mix} = 0.5 \times 5.78 + 0.5 \times 3.62 = 4.70$ MPa

$T_{c\,mix} = 0.5 \times 351.3 + 0.5 \times 339.2 = 345.25$ K

Reduced properties 1: $P_{r1} = \dfrac{1.2}{4.70} = 0.255, \quad T_{r1} = \dfrac{293.15}{345.25} = 0.849$

Fig. D.1: $\left(h_1^* - h_1\right) = 0.4 \times RT_c = 0.4 \times 0.1145 \times 345.25 = 15.81$ kJ/kg

Reduced properties 1: $P_{r2} = \dfrac{1.2}{4.70} = 0.255, \quad T_{r2} = \dfrac{393.15}{345.25} = 1.139$

Fig. D.1: $\left(h_2^* - h_2\right) = 0.2 \times RT_c = 0.2 \times 0.1145 \times 345.25 = 7.906$ kJ/kg

The energy equation gives

$$ {}_1q_2 = (h_2 - h_1) = \left(h_2 - h_2^*\right) + \left(h_2^* - h_1^*\right) + \left(h_1^* - h_1\right) $$

$$ = -7.906 + 0.8065\,(120 - 20) + 15.81 $$

$$ = \mathbf{88.55\ kJ/kg\ mix} $$

Table B.4.2: $q = h_2 - h_1 = 393.13 - 290.51 =$ **102.62 kJ/kg**

The main difference is in the value of specific heat, about 1 kJ/kg-K at the avg. T, whereas it is 0.8 kJ/kg-K at 25°C.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.125

A 2 kg mixture of 50% argon and 50% nitrogen by mass is in a tank at 2 MPa, 180 K. How large is the volume using a model of (a) ideal gas and (b) Redlich Kwong equation of state with a, b for a mixture.

a) Ideal gas mixture

Eq.11.15: $R_{mix} = \sum c_i R_i = 0.5 \times 0.2081 + 0.5 \times 0.2968 = 0.25245$ kJ/kg K

$$V = \frac{mR_{mix}T}{P} = \frac{2 \times 0.25245 \times 180}{2000} = \mathbf{0.0454\ m^3}$$

b) Redlich Kwong equation of state. Before we can do the parameters a, b for the mixture we need the individual component parameters, Eq.12.54, 13.55.

$$a_{Ar} = 0.42748 \frac{R^2 T_c^{5/2}}{P_c} = 0.42748 \frac{0.2081^2 \times 150.8^{2.5}}{4870} = 1.06154$$

$$a_{N2} = 0.42748 \frac{R^2 T_c^{5/2}}{P_c} = 0.42748 \frac{0.2968^2 \times 126.2^{2.5}}{3390} = 1.98743$$

$$b_{Ar} = 0.08664 \frac{RT_c}{P_c} = 0.08664 \frac{0.2081 \times 150.8}{4870} = 0.000\ 558$$

$$b_{N2} = 0.08664 \frac{RT_c}{P_c} = 0.08664 \frac{0.2968 \times 126.2}{3390} = 0.000\ 957$$

Now the mixture parameters are from Eq.12.84

$$a_{mix} = \left(\sum c_i a_i^{1/2} \right)^2 = (0.5 \times \sqrt{1.06154} + 0.5 \times \sqrt{1.98743})^2 = 1.4885$$

$$b_{mix} = \sum c_i b_i = 0.5 \times 0.000\ 558 + 0.5 \times 0.000\ 957 = 0.000\ 758$$

Using now Eq.12.53: $P = \frac{RT}{v - b} - \frac{a}{v(v + b)T^{1/2}}$

$$2000 = \frac{0.25245 \times 180}{v - 0.000\ 758} - \frac{1.4885}{v(v + 0.000\ 758)\ 180^{1/2}}$$

By trial and error we find the specific volume, $v = 0.02102\ m^3/kg$

$$V = mv = \mathbf{0.04204\ m^3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.126

A modern jet engine operates so that the fuel is sprayed into air at a P, T higher than the fuel critical point. Assume we have a rich mixture of 50% n-octane and 50% air by mole at 500 K and 3.5 MPa near the nozzle exit. Do I need to treat this as a real gas mixture or is an ideal gas assumption reasonable? To answer find Z and the enthalpy departure for the mixture assuming Kay's rule and the generalized charts.

The mole fractions are:

$y_{C8H18} = 0.5, \quad y_{N2} = 0.5 \times 0.79 = 0.395, \quad y_{O2} = 0.5 \times 0.21 = 0.105$

Eq.11.5:

$$M_{mix} = \sum y_i M_i = 0.5 \times 114.232 + 0.395 \times 28.013 + 0.105 \times 31.999$$
$$= 71.541$$

Kay's rule Eq.12.84

$$P_{c\,mix} = 0.5 \times 2.49 + 0.395 \times 3.39 + 0.105 \times 5.04 = 3.113 \text{ MPa}$$

$$T_{c\,mix} = 0.5 \times 568.8 + 0.395 \times 126.2 + 0.105 \times 154.6 = 350.5 \text{ K}$$

Reduced properties: $P_r = \frac{3.5}{3.113} = 1.124, \quad T_r = \frac{500}{350.5} = 1.427$

Fig. D.1: **Z = 0.87** I must treat it as a real gas mixture.

Fig. D.2 $h^* - h = 0.70 \times RT_c = 0.70 \times \frac{8.3145}{71.541} \times 350.5 =$ **28.51 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.127

A mixture of 60% ethylene and 40% acetylene by moles is at 6 MPa, 300 K. The mixture flows through a preheater where it is heated to 400 K at constant P. Using the Redlich Kwong equation of state with a, b for a mixture find the inlet specific volume. Repeat using Kays rule and the generalized charts.

To do the EOS we need the gas constant, so from Eq.11.5 we get

$$M_{mix} = \sum y_i M_i = 0.6 \times 28.054 + 0.4 \times 26.068 = 27.26$$

$$R_{mix} = 8.3145/27.26 = 0.305 \text{ kJ/kg K}$$

Redlich Kwong EOS the individual component parameters, Eq.12.54, 12.55.

$$a_{C2H4} = 0.42748 \frac{R^2 T_c^{5/2}}{P_c} = 0.42748 \frac{0.2964^2 \times 282.4^{2.5}}{5040} = 9.9863$$

$$a_{C2H2} = 0.42748 \frac{R^2 T_c^{5/2}}{P_c} = 0.42748 \frac{0.3193^2 \times 308.3^{2.5}}{6140} = 11.8462$$

$$b_{C2H4} = 0.08664 \frac{RT_c}{P_c} = 0.08664 \frac{0.2964 \times 282.4}{5040} = 0.001\,439$$

$$b_{C2H2} = 0.08664 \frac{RT_c}{P_c} = 0.08664 \frac{0.3193 \times 308.3}{6140} = 0.001\,389$$

Now the mixture parameters are from Eq.12.84 so we need the mass fractions

$$c_{C2H4} = \frac{y M}{M_{mix}} = \frac{0.6 \times 28.054}{27.26} = 0.6175, \qquad c_{C2H4} = 1 - c_{C2H4} = 0.3825$$

$$a_{mix} = \left(\sum c_i a_i^{1/2} \right)^2 = (0.6175 \times \sqrt{9.9863} + 0.3825 \times \sqrt{11.8462})^2 = 10.679$$

$$b_{mix} = \sum c_i b_i = 0.6175 \times 0.001\,439 + 0.3825 \times 0.001\,389 = 0.001\,42$$

Using now Eq.12.53: $$P = \frac{RT}{v - b} - \frac{a}{v(v + b)T^{1/2}}$$

$$6000 = \frac{0.305 \times 300}{v - 0.001\,42} - \frac{10.679}{v(v + 0.001\,42)\, 300^{1/2}}$$

By trial and error we find the specific volume, v = **0.006683 m^3/kg**

Kay's rule Eq.12.84

$$P_{c\,mix} = 0.6 \times 5.04 + 0.4 \times 6.14 = 5.48 \text{ MPa}$$

$$T_{c\,mix} = 0.6 \times 282.4 + 0.4 \times 308.3 = 292.8 \text{ K}$$

Reduced properties: $P_r = \frac{6}{5.48} = 1.095$, $T_r = \frac{300}{292.8} = 1.025$

Fig. D.1: Z = 0.4 (difficult to read)

$$v = ZRT/P = 0.4 \times 0.305 \times 300 / 6000 = \textbf{0.0061 m}^3\textbf{/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.128

For the previous problem, find the specific heat transfer using Kay's rule and the generalized charts.

To do the EOS we need the gas constant, so from Eq.11.5 we get

$$M_{mix} = \sum y_i M_i = 0.6 \times 28.054 + 0.4 \times 26.068 = 27.26$$

$$R_{mix} = 8.3145/27.26 = 0.305 \text{ kJ/kg K}$$

$$c_{C2H4} = \frac{y\,M}{M_{mix}} = \frac{0.6 \times 28.054}{27.26} = 0.6175, \qquad c_{C2H4} = 1 - c_{C2H4} = 0.3825$$

$$C_{P\,mix} = \sum c_i C_{P\,i} = 0.6175 \times 1.548 + 0.3825 \times 1.699 = 1.606 \text{ kJ/kg K}$$

Kay's rule Eq.12.84

$$P_{c\,mix} = 0.6 \times 5.04 + 0.4 \times 6.14 = 5.48 \text{ MPa}$$

$$T_{c\,mix} = 0.6 \times 282.4 + 0.4 \times 308.3 = 292.8 \text{ K}$$

Reduced properties 1: $P_{r1} = \frac{6}{5.48} = 1.095, \quad T_{r1} = \frac{300}{292.8} = 1.025$

Fig. D.1: $\left(h_1^* - h_1\right) = 2.1 \times RT_c = 2.1 \times 0.305 \times 292.8 = 187.5 \text{ kJ/kg}$

Reduced properties 2: $P_{r2} = \frac{6}{5.48} = 1.095, \quad T_{r2} = \frac{400}{292.8} = 1.366$

Fig. D.1: $\left(h_2^* - h_2\right) = 0.7 \times RT_c = 0.7 \times 0.305 \times 292.8 = 62.5 \text{ kJ/kg}$

The energy equation gives

$$_1q_2 = (h_2 - h_1) = \left(h_2 - h_2^*\right) + \left(h_2^* - h_1^*\right) + \left(h_1^* - h_1\right)$$

$$= -62.5 + 1.606\,(400 - 300) + 187.5$$

$$= \mathbf{285.6 \text{ kJ/kg mix}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.129

A gas mixture of a known composition is frequently required for different purposes, e.g., in the calibration of gas analyzers. It is desired to prepare a gas mixture of 80% ethylene and 20% carbon dioxide (mole basis) at 10 MPa, 25°C in an uninsulated, rigid 50-L tank. The tank is initially to contain CO2 at 25°C and some pressure *P*1. The valve to a line flowing C2H4 at 25°C, 10 MPa, is now opened slightly, and remains open until the tank reaches 10 MPa, at which point the temperature can be assumed to be 25°C. Assume that the gas mixture so prepared can be represented by Kay's rule and the generalized charts. Given the desired final state, what is the initial pressure of the carbon dioxide, *P*1?

	A = C_2H_4, B = CO_2 T_1 = 25 °C P_2 = 10 MPa, T_2 = 25 °C y_{A2} = 0.8, y_{B2} = 0.2	
Mixture at 2 :

$$P_{C2} = 0.8 \times 5.04 + 0.2 \times 7.38 = 5.508 \text{ MPa}$$

$$T_{C2} = 0.8 \times 282.4 + 0.2 \times 304.1 = 286.7 \text{ K}$$

$$T_{r2} = 298.15/286.7 = 1.040;\ P_{r2} = 10/5.508 = 1.816$$

D.1 : $Z_2 = 0.32$

$$n_2 = \frac{P_2 V}{Z_2 \bar{R} T_2} = \frac{10\,000 \times 0.05}{0.32 \times 8.3145 \times 298.2} = 0.6302 \text{ kmol}$$

$$n_{A2} = n_i = 0.8\ n_2 = 0.5042 \text{ kmol } C_2H_4$$

$$n_{B2} = n_1 = 0.2\ n_2 = 0.1260 \text{ kmol } CO_2$$

$$T_{r1} = \frac{298.2}{304.1} = 0.981$$

$$P_{r1} = \frac{n_1 Z_{B1} \bar{R} T_1}{P_{CB} V} = \frac{0.126\ Z_{B1} \times 8.3145 \times 298.2}{7380 \times 0.05} = 0.8466\ Z_{B1}$$

By trial & error: $P_{r1} = 0.618$ & $Z_{B1} = 0.73$

$\Rightarrow P_1 = 0.618 \times 7.38 =$ **4.56 MPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.130

One kmol/s of saturated liquid methane, CH_4, at 1 MPa and 2 kmol/s of ethane, C_2H_6, at 250°C, 1 MPa are fed to a mixing chamber with the resultant mixture exiting at 50°C, 1 MPa. Assume that Kay's rule applies to the mixture and determine the heat transfer in the process.

Control volume the mixing chamber, inlet CH_4 is 1, inlet C_2H_6 is 2 and the exit state is 3. Energy equation is

$$\dot{Q}_{CV} = \dot{n}_3 \bar{h}_3 - \dot{n}_1 \bar{h}_1 - \dot{n}_2 \bar{h}_2$$

Select the ideal gas reference temperature to be T_3 and use the generalized charts for all three states.

$P_{r1} = P_{rsat} = 1/4.60 = 0.2174 \Rightarrow \quad T_{rsat} = 0.783,$

$T_1 = 0.783 \times 190.4 = 149.1$ K, $\quad \Delta h_1 = 4.57$

$P_{r2} = 1/4.88 = 0.205, \quad T_{r2} = 523/305.4 = 1.713, \quad \Delta h_2 = 0.08$

$$\bar{h}_1 = \bar{C}_1(T_1 - T_3) - \Delta h_1 \bar{R} T_c = 36.15(149.1 - 323.2) - 4.57 \times 8.3145 \times 190.4$$
$$= -13528 \text{ kJ/kmol}$$

$$\bar{h}_2 = \bar{C}_2(T_2 - T_3) - \Delta h_2 \bar{R} T_c = 53.11(250 - 50) - 0.08 \times 8.3145 \times 305.4$$
$$= 10\,419 \text{ kJ/kmol}$$

Kay's rule Eq.12.84

$T_{cmix} = (1 \times 190.4 + 2 \times 305.4)/3 = 267.1$ K

$P_{cmix} = (1 \times 4.60 + 2 \times 4.88)/3 = 4.79$ MPa

$T_{r3} = 323.2/267.1 = 1.21 \ , \quad P_{r3} = 1/4.79 = 0.21, \quad \Delta h_3 = 0.15$

$$\bar{h}_3 = 0 - 0.15 \times 267.1 \times 8.3145 = -333 \text{ kJ/kmol}$$

$$\dot{Q}_{CV} = 3(-333) - 1(-13528) - 2(10\,419) = \mathbf{-8309\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.131

Saturated-liquid ethane at $T_1 = 14°C$ is throttled into a steady flow mixing chamber at the rate of 0.25 kmol/s. Argon gas at $T_2 = 25°C$, $P_2 = 800$ kPa, enters the chamber at the rate of 0.75 kmol/s. Heat is transferred to the chamber from a heat source at a constant temperature of 150^oC at a rate such that a gas mixture exits the chamber at $T_3 = 120^oC$, $P_3 = 800$ kPa. Find the rate of heat transfer and the rate of entropy generation.

Argon, $T_{a2} = 25^oC$, $P_2 = 800$ kPa, $\dot{n}_2 = 0.75$ kmol/s

$T_{ca} = 150$ K, $P_{ca} = 4.87$ MPa, $M_a = 39.948$ kg/kmol, $C_{pa} = 0.52$ kJ/kg K

$\bar{h}_{a3} - \bar{h}_{a2} = M_a C_{pa}(T_3 - T_{a2}) = 1973.4$ kJ/kmol

Inlet: Ethane, $T_{b1} = 14^oC$, sat. liq., $x_{b1} = 0$, $\dot{n}_1 = 0.25$ kmol/s

$T_{cb} = 305.4$ K, $P_{cb} = 4.88$ MPa, $M_b = 30.07$ kg/kmol, $C_{pb} = 1.766$ kJ/kg-K

$T_{r1} = 0.94$, $P_{b1} = P_{r1}P_{cb} = 0.69 \times 4880 = 3367$ kPa

$\bar{h}^*_{b1} - \bar{h}_{b1} = 3.81\ \bar{R}T_{cb} = 9674.5$ kJ/kmol, $\bar{s}^*_{b1} - \bar{s}_{b1} = 3.74\ \bar{R} = 31.1$

$\bar{h}^*_{b3} - \bar{h}^*_{b1} = M_b C_{pb}(T_3 - T_{b1}) = 5629.6$ kJ/kmol

Exit: Mix, $T_3 = 120^oC$, $P_3 = 800$ kPa consider this an ideal gas mixture.

Energy Eq.: $\dot{n}_1\bar{h}_{b1} + \dot{n}_2\bar{h}_{a2} + \dot{Q} = \dot{n}_3\bar{h}_3 = \dot{n}_1\bar{h}_{b3} + \dot{n}_2\bar{h}_{a3}$

$\dot{Q} = \dot{n}_1(\bar{h}_{b3} - \bar{h}_{b1}) + \dot{n}_2(\bar{h}_{a3} - \bar{h}_{a2}) = 0.25\ (5629.6 + 9674.5) + 0.75(1973.4)$

$= \mathbf{5306\ kW}$

Entropy Eq.: $\dot{S}_{gen} = \dot{n}_1(\bar{s}_{b3} - \bar{s}_{b1}) + \dot{n}_2(\bar{s}_{a3} - \bar{s}_{a2}) - \dot{Q}/T_H$; $T_H = 150^oC$

$y_a = \dot{n}_2/\dot{n}_{tot} = 0.75$; $y_b = \dot{n}_1/\dot{n}_{tot} = 0.25$

$$\bar{s}_{a3} - \bar{s}_{a2} = M_a C_{pa} \ln\frac{T_3}{T_{a2}} - \bar{R} \ln\frac{y_a P_3}{P_{a2}} = 8.14 \text{ kJ/kmol-K}$$

$$\bar{s}_{b3} - \bar{s}_{b1} = M_b C_{pb} \ln\frac{T_3}{T_{b1}} - \bar{R} \ln\frac{y_b P_3}{P_{b1}} + \bar{s}^*_{b1} - \bar{s}_{b1} =$$

$$= 40.172 + 31.1 = 71.27 \text{ kJ/kmol K}$$

$\dot{S}_{gen} = 0.25 \times 71.27 + 0.75 \times 8.14 - 5306 / 423 = \mathbf{11.38\ kW/K}$

12.132

A cylinder/piston contains a gas mixture, 50% CO2 and 50% C2H6 (mole basis) at 700 kPa, 35°C, at which point the cylinder volume is 5 L. The mixture is now compressed to 5.5 MPa in a reversible isothermal process. Calculate the heat transfer and work for the process, using the following model for the gas mixture:

a. Ideal gas mixture.

b. Kay's rule and the generalized charts.

a) Ideal gas mixture

$$U_2 - U_1 = mC_{v\,mix}(T_2 - T_1) = 0$$

$$Q_{12} = W_{12} = \int P\,dV = P_1V_1 \ln(V_2/V_1) = - P_1V_1 \ln(P_2/P_1)$$

$$= - 700 \times 0.005 \ln(5500/700) = \mathbf{-7.71\ kJ}$$

b) Kay's rule

$$T_{cmix} = 0.5 \times 304.1 + 0.5 \times 305.4 = 304.75\ K$$

$$P_{cmix} = 0.5 \times 7.38 + 0.5 \times 4.88 = 6.13\ MPa$$

$$T_{r1} = 308.15/304.75 = 1.011, \quad P_{r1} = 0.7/6.13 = 0.1142$$

$$Z_1 = 0.96, \quad \Delta h_1 = 0.12, \quad \Delta s_1 = 0.08$$

$$n = P_1V_1/Z_1\bar{R}\,T_1 = \frac{700*0.005}{0.962*8.3145*308.15} = 0.00142\ kmol$$

$$T_{r2} = T_{r1}\ , \quad P_{r2} = 5.5/6.13 = 0.897,$$

$$Z_2 = 0.58, \quad \Delta h_2 = 1.35, \quad \Delta s_2 = 1.0$$

$$\bar{h}_2 - \bar{h}_1 = (\bar{h}_2 - \bar{h}_1) - \bar{R}\,T_c(\Delta h_2 - \Delta h_1)$$

$$= 0 - 8.3145 \times 304.75(1.35 - 0.12) = - 3117$$

$$\bar{u}_2 - \bar{u}_1 = \bar{h}_2 - \bar{h}_1 + \bar{R}T(Z_1 - Z_2) = - 3117$$

$$+ 8.3145 \times 308.15(0.96 - 0.58) = -2143\ kJ/kmol$$

$$Q_{12} = nT(\bar{s}_2 - \bar{s}_1)_T = 0.00142 \times 308.15 \times 8.3145[\ 0 - \ln(5.5/0.7) - 1.0$$

$$+ 0.08\ ] = \mathbf{-\ 10.85\ kJ}$$

$$W_{12} = Q_{12} - n(\bar{u}_2 - \bar{u}_1) = -10.85 - 0.00142(-2143) = \mathbf{-\ 7.81\ kJ}$$

12.133

A cylinder/piston contains a gas mixture, 50% CO_2 and 50% C_2H_6 (mole basis) at 700 kPa, 35°C, at which point the cylinder volume is 5 L. The mixture is now compressed to 5.5 MPa in a reversible isothermal process. Calculate the heat transfer and work for the process, using the following model for the gas mixture:

a. Ideal gas mixture. b. The van der Waals equation of state.

a) Ideal gas mixture

$$U_2 - U_1 = mC_{v\,mix}(T_2 - T_1) = 0$$

$$Q_{12} = W_{12} = \int P\,dV = P_1V_1 \ln(V_2/V_1) = - P_1V_1 \ln(P_2/P_1)$$

$$= - 700 \times 0.005 \ln(5500/700) = \mathbf{-7.71\ kJ}$$

b) van der waal's equation

For CO_2 : $b = \bar{R}\,T_c/8P_c = 8.3145 \times 304.1/8 \times 7380 = 0.04282$

$$a = 27\,P_c\,b^2 = 27 \times 7380 \times 0.04282^2 = 365.45$$

For C_2H_6 : $b = \bar{R}\,T_c/8P_c = 8.3145 \times 305.4/8 \times 4880 = 0.06504$

$$a = 27\,P_c\,b^2 = 27 \times 4880 \times 0.06504^2 = 557.41$$

$$a_{mix} = (0.5\sqrt{365.45} + 0.5\sqrt{557.41})^2 = 456.384$$

$$b_{mix} = 0.5 \times 0.04282 + 0.5 \times 0.06504 = 0.05393$$

$$\frac{8.3145*308.2}{\bar{v}_1 - 0.05393} - \frac{456.384}{\bar{v}_1^2} - 700 = 0$$

By trial and error: $\bar{v}_1 = 3.5329\ m^3/kmol$

$$\frac{8.3145*308.2}{\bar{v}_2 - 0.05393} - \frac{456.384}{\bar{v}_2^2} - 5500 = 0$$

By trial and error: $\bar{v}_2 = 0.2815\ m^3/kmol$

$$n = V_1/\bar{v}_1 = 0.005/3.5329 = 0.00142$$

$$Q_{12} = nT(\bar{s}_2 - \bar{s}_1)_T = n\,\bar{R}\,T \ln \frac{\bar{v}_2 - b}{\bar{v}_1 - b}$$

$$= 0.00142 \times 8.3145 \times 308.2 \ln \frac{0.2815 - 0.05392}{3.5329 - 0.05392} = \mathbf{-\ 9.93\ kJ}$$

$$U_2 - U_1 = 0.00142 \times 456.39(3.5329^{-1} - 0.2815^{-1}) = -2.12\ kJ$$

$$Q_{12} = U_2 - U_1 + W_{12} \Rightarrow W_{12} = -9.93 -(-2.12) = \mathbf{-7.81\ kJ}$$

12.134

Verify that the ideal gas part of Helmholtz function substituted in Eq.12.89 does lead to the ideal gas law as in note after Eq.12.97.

The ideal gas Helmholtz function is from its definition, see Eq.12.12,

$$a^* = u^* - Ts^* = h^* - RT - T\,s^*$$

We have

$$h^* = h_o^* + \int C_{Po}\,dT$$

$$s^* = s_o^* + \int \frac{C_{Po}}{T}\,dT - R\,\ln\left(\frac{\rho T}{\rho_o T_o}\right)$$

Now from Eq.12.89 we need to look at $\left(\frac{\partial a^*}{\partial \rho}\right)_T$ so following 12.92

$$\left(\frac{\partial a^*}{\partial \rho}\right)_T = \left(\frac{\partial h^*}{\partial \rho}\right)_T - \left(\frac{\partial RT}{\partial \rho}\right)_T - T\left(\frac{\partial s^*}{\partial \rho}\right)_T$$

$$= 0 - 0 + TR\,\frac{\partial}{\partial \rho}\left(\ln\frac{\rho T}{\rho_o T_o}\right)_T$$

$$= RT / \rho$$

So then

$$\rho^2\left(\frac{\partial a^*}{\partial \rho}\right)_T = P = \rho RT \qquad \text{Ideal gas OK}$$

12.135

Gases like argon and neon have constant specific heats. Develop an expression for the ideal gas contribution to Helmholtz function in Eq.12.92 for these cases.

The ideal gas Helmholtz function is from its definition, see Eq.12.92,

$$a^* = u^* - Ts^* = h^* - RT - T\,s^*$$

We have

$$h^* = h_o^* + \int C_{Po}\,dT = h_o^* + C_{Po}(T - T_o)$$

$$s^* = s_o^* + \int \frac{C_{Po}}{T}\,dT - R\ln\left(\frac{\rho T}{\rho_o T_o}\right)$$

$$= s_o^* + C_{Po}\ln(T/T_o) - R\ln\left(\frac{\rho T}{\rho_o T_o}\right)$$

So now we get

$$a^* = h_o^* + C_{Po}(T - T_o) - RT - T\,s^*$$

$$= h_o^* - T\,s_o^* + C_{Po}(T - T_o) - C_{Po}T\ln\left(\frac{T}{T_o}\right) - RT + RT\ln\left(\frac{\rho T}{\rho_o T_o}\right)$$

$$= C_o + C_1\,T - C_2\,T\ln\left(\frac{T}{T_o}\right) + RT\ln\left(\frac{\rho}{\rho_o}\right)$$

where

$$C_o = h_o^* - C_{Po}T_o\,; \qquad C_1 = C_{Po} - R - s_o^*\,; \qquad C_2 = C_{Po} - R$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.136

Find an expression for the change in Helmholtz function for a gas with an EOS as $P(v - b) = RT$.

From Eq.12.31 we get

$$du_T = [\ T \left(\frac{\partial P}{\partial T}\right)_v - P\ ]\ dv_T = [\ T\ (\frac{R}{v - b}) - P\ ]\ dv_T = [\ P - P]\ dv_T = 0$$

From Eq.12.32 or Eq.12.34 we get

$$ds_T = -\left(\frac{\partial v}{\partial T}\right)_P dP_T = \left(\frac{\partial P}{\partial T}\right)_v dv_T$$

$$= -\frac{R}{P} dP_T = \frac{R}{v - b} dv_T$$

Now the changes in u and s can be integrated to find

$$(u_2 - u_1)_T = 0$$

$$(s_2 - s_1)_T = -R \ln \frac{P_2}{P_1} = R \ln \frac{v_2 - b}{v_1 - b}$$

to this we now need to add the variation due to T. For this we get

$$(u_2 - u_1)_v = \int_1^2 C_v\, dT \qquad \text{and} \qquad (s_2 - s_1)_v = \int_1^2 \frac{C_v}{T} dT$$

Finally since the Helmholtz function contains the product Ts we need the absolute value of the entropy so

$$s_1 = s_o + \int_o^1 \frac{C_v}{T} dT + R \ln \frac{v_1 - b}{v_o - b}$$

Then the change in Helmholtz function becomes

$$a_2 - a_1 = u_2 - u_1 - T_2 s_2 + T_1 s_1 = u_2 - u_1 - T_2(s_2 - s_1) + (T_1 - T_2)\, s_1$$

$$= \int_1^2 C_v\, dT - T_2[\ \int_1^2 \frac{C_v}{T} dT + R \ln \frac{v_2 - b}{v_1 - b}\ ] + (T_1 - T_2)\, s_1$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.137

Use the equation of state in Example 12.3 and find an expression for isothermal changes in Helmholtz function between two states.

The EOS is

$$\frac{Pv}{RT} = 1 - C'\frac{P}{T^4} \qquad \text{or} \qquad v = \frac{RT}{P} - \frac{C}{T^3}$$

and we use the isothermal changes found in Ex.14.3 as

$$(h_2 - h_1)_T = -\frac{4C}{T^3}(P_2 - P_1)_T$$

$$(s_2 - s_1)_T = -R \ln\left(\frac{P_2}{P_1}\right)_T - \frac{3C}{T^4}(P_2 - P_1)_T$$

As Helmholtz function is: a = u – Ts; we get

$$\begin{aligned}(a_2 - a_1)_T &= (u_2 - u_1)_T - T(s_2 - s_1)_T \\ &= (h_2 - h_1)_T - (P_2v_2 - P_1v_1) - T(s_2 - s_1)_T \\ &= -\frac{4C}{T^3}(P_2 - P_1)_T - [RT_2 - RT_1 - \frac{C}{T^3}(P_2 - P_1)_T\,] \\ &\quad + RT \ln\left(\frac{P_2}{P_1}\right)_T + \frac{3C}{T^3}(P_2 - P_1)_T \\ &= -\frac{4C}{T^3}(P_2 - P_1)_T + \frac{C}{T^3}(P_2 - P_1)_T + RT \ln\left(\frac{P_2}{P_1}\right)_T + \frac{3C}{T^3}(P_2 - P_1)_T\end{aligned}$$

This now reduces to the final answer

$$(a_2 - a_1)_T = RT \ln\left(\frac{P_2}{P_1}\right)_T$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.138

Assume a Helmholtz equation as

$$a^* = C_o + C_1\, T - C_2\, T \ln\left(\frac{T}{T_o}\right) + RT \ln\left(\frac{\rho}{\rho_o}\right)$$

where C_o, C_1, C_2 are constants and T_o and ρ_o reference values for temperature and density, see Eqs. 12.92 - 95. Find the properties P, u and s from this expression. Is anything assumed for this particular form.

Given Helmholtz function we can find the pressure and entropy from Eq. 12.21 and then u from the definition: $a = u - Ts$.

$$a^* = C_o + C_1\, T - C_2\, T \ln\left(\frac{T}{T_o}\right) - RT \ln\left(\frac{v}{v_o}\right)$$

$$\left(\frac{\partial a^*}{\partial v}\right)_T = -RT \frac{\partial}{\partial v} \ln\left(\frac{v}{v_o}\right) = -RT / v$$

$$P = -\left(\frac{\partial a^*}{\partial v}\right)_T = RT / v \qquad \text{i.e. Ideal gas.}$$

$$s = -\left(\frac{\partial a^*}{\partial T}\right)_v = -C_1 + C_2 \ln\left(\frac{T}{T_o}\right) + C_2 + R \ln\left(\frac{v}{v_o}\right)$$

Notice how it looks like Eq.6.17.

$$u = a + Ts = C_o + C_1\, T - C_2\, T \ln\left(\frac{T}{T_o}\right) - RT \ln\left(\frac{v}{v_o}\right)$$

$$- C_1 T + C_2 T \ln\left(\frac{T}{T_o}\right) + C_2 T + RT \ln\left(\frac{v}{v_o}\right)$$

$$= C_o + C_2 T$$

We find that u is linear in T.

Not only is it ideal gas but it also has constant specific heats.

12.139

Saturated liquid ethane at 2.44 MPa enters a heat exchanger and is brought to 611 K at constant pressure, after which it enters a reversible adiabatic turbine where it expands to 100 kPa. Find the heat transfer in the heat exchanger, the turbine exit temperature and turbine work.

From D.2,

$P_{r1} = 2.44/4.88 = 0.50$, $T_{r1} = 0.89$, $T_1 = 0.89 \times 305.4 = 271.8$ K

$(h_1^* - h_1) = 0.2765 \times 305.4 \times 4.12 = 347.9$

$(h_2^* - h_1^*) = 1.766\ (611 - 271.8) = 599.0$

$P_{r2} = 0.50$, $T_{r2} = 611/305.4 = 2.00$

From D.2: $(h_2^* - h_2) = RT_c \times 0.14 = 0.2765 \times 305.4 \times 0.14 = 11.8$

$q = (h_2 - h_1) = -11.8 + 599.0 + 347.9 =$ **935.1 kJ/kg**

From D.3,

$(s_2^* - s_2) = 0.2765 \times 0.05 = 0.0138$

$$(s_3^* - s_2^*) = 1.766 \ln \frac{T_3}{611} - 0.2765 \ln \frac{100}{2440}$$

Assume $T_3 = 368$ K , $T_{r3} = 1.205$

at $P_{r3} = 0.020$

$(s_3^* - s_2^*) = -0.8954 + 0.8833 = -0.0121$

From D.3,

$(s_3^* - s_3) = 0.2765 \times 0.01 = 0.0028$

$(s_3 - s_2) = -0.0028 - 0.0121 + 0.0138 \approx 0$ OK

Therefore, $T_3 =$ **368 K**

From D.2,

$(h_3^* - h_3) = 0.2765 \times 305.4 \times 0.01 = 0.8$

$w = (h_2 - h_3) = -11.8 + 1.766\ (611 - 368) + 0.8 =$ **418.1 kJ/kg**

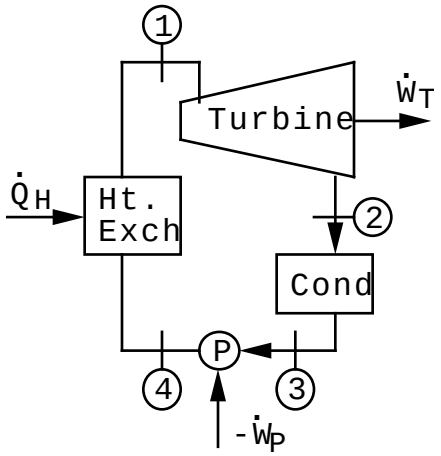
12.141

A newly developed compound is being considered for use as the working fluid in a small Rankine-cycle power plant driven by a supply of waste heat. Assume the cycle is ideal, with saturated vapor at 200°C entering the turbine and saturated liquid at 20°C exiting the condenser. The only properties known for this compound are molecular weight of 80 kg/kmol, ideal gas heat capacity C_{PO}= 0.80 kJ/kg K and T_C = 500 K, P_C = 5 MPa. Calculate the work input, per kilogram, to the pump and the cycle thermal efficiency.



$T_1 = 200^oC = 473.2$ K, $x_1 = 1.0$

$T_3 = 20^oC = 293.2$ K, $x_3 = 0.0$

Properties known:

M = 80, C_{PO} = 0.8 kJ/kg K

T_C = 500 K, P_C = 5.0 MPa

$$T_{r1} = \frac{473.2}{500} = 0.946\ , \quad T_{r3} = \frac{293.2}{500} = 0.586$$

R = R/M = 8.31451/80 = 0.10393 kJ/kg K

From Fig. D.1,

$P_{r1} = 0.72$, $P_1 = 0.72 \times 5 = 3.6$ MPa = P_4

$P_{r3} = 0.023$, $P_3 = 0.115$ MPa = P_2 , $Z_{F3} = 0.004$

$$v_{F3} = \frac{Z_{F3}RT_3}{P_3} = \frac{0.004 \times 0.10393 \times 293.2}{115} = 0.00106\ m^3/kg$$

$$w_P = -\int_3^4 vdP \approx v_{F3}(P_4 - P_3) = -0.00106(3600-115) = \mathbf{-3.7\ kJ/kg}$$

$q_H + h_4 = h_1$, but $h_3 = h_4 + w_P$ => $q_H = (h_1 - h_3) + w_P$

From Fig. D.2:

$(h_1^* - h_1) = RT_C \times 1.25 = 0.103\ 93 \times 500 \times 1.25 = 64.9$ kJ/kg

$(h_3^* - h_3) = 0.103\ 93 \times 500 \times 5.2 = 270.2$ kJ/kg

$(h_1^* - h_3^*) = C_{P0}(T_1 - T_3) = 0.80(200-20) = 144.0$ kJ/kg

$(h_1 - h_3) = -64.9 + 144.0 + 270.2 = 349.3$ kJ/kg

$q_H = 349.3 + (-3.7) = 345.6$ kJ/kg

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Turbine, $(s_2 - s_1) = 0 = -(s_2^* - s_2) + (s_2^* - s_1^*) + (s_1^* - s_1)$

From Fig. D.3,

$(s_1^* - s_1) = 0.10393 \times 0.99 = 0.1029$ kJ/kg K

$$(s_2^* - s_1^*) = 0.80 \ln \frac{293.2}{473.2} - 0.103\,93 \ln \frac{115}{3600} = -0.0250$$

Substituting,

$s_2^* - s_2 = +0.1029 - 0.0250 = 0.0779 = (s_2^* - s_{F2}) - x_2 s_{FG2}$

$0.0779 = 0.103\,93 \times 8.85 - x_2 \times 0.103\,93(8.85-0.06) \quad \Rightarrow \quad x_2 = 0.922$

$(h_2^* - h_2) = (h_2^* - h_{F2}) - x_2 h_{FG2}$

From Fig. D.2,

$h_{FG2} = 0.10393 \times 500\ (5.2-0.07) = 266.6$

$(h_2^* - h_2) = 270.2 - 0.922 \times 266.6 = 25.0$

$w_T = (h_1 - h_2) = -64.9 + 144.0 + 25.0 = 104.1$ kJ/kg

$$\eta_{TH} = \frac{w_{NET}}{q_H} = \frac{104.1-3.7}{345.6} = \mathbf{0.29}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.142

A 200-L rigid tank contains propane at 400 K, 3.5 MPa. A valve is opened, and propane flows out until half the initial mass has escaped, at which point the valve is closed. During this process the mass remaining inside the tank expands according to the relation $Pv^{1.4}$ = constant. Calculate the heat transfer to the tank during the process.

C_3H_8: V = 200 L, T_1 = 400 K, P_1 = 3.5 MPa

Flow out to $m_2 = m_1/2$; $Pv^{1.4}$ = const inside

$T_{r1} = \dfrac{400}{369.8} = 1.082$, $P_{r1} = \dfrac{3.5}{4.25} = 0.824$ Fig D.1: $Z_1 = 0.74$

$v_1 = \dfrac{0.74 \times 0.188\ 55 \times 400}{3500} = 0.01594$, $v_2 = 2v_1 = 0.03188$

$m_1 = \dfrac{0.2}{0.015\ 94} = 12.55$ kg, $m_2 = \dfrac{1}{2} m_1 = 6.275$ kg,

$P_2 = P_1 \left(\dfrac{v_1}{v_2}\right)^{1.4} = \dfrac{3500}{2^{1.4}} = 1326$ kPa

$P_{r2} = \dfrac{1.326}{4.25} = 0.312$

$P_2 v_2 = Z_2 R T_2$

Trial & error: saturated with $T_2 = 0.826 \times 369.8 = 305.5$ K &

$Z_2 = \dfrac{1326 \times 0.03188}{0.188\ 55 \times 305.5} = 0.734$

$Z_2 = Z_{F2} + x_2(Z_{G2} - Z_{F2}) = 0.734 = 0.05 + x_2(0.78\text{-}0.05)$ => $x_2 = 0.937$

$(h_1^* - h_1) = 0.188\ 55 \times 369.8(0.9) = 62.8$

$(h_2^* - h_1^*) = 1.6794(305.5\text{-}400) = -158.7$

$(h_2^* - h_2) = (h_2^* - h_{F2}) - x_2 h_{FG2} = 0.188\ 55 \times 369.8 \left[4.41 - 0.937(4.41\text{-}0.55) \right]$

$= 55.3$

Energy Eq.: $Q_{CV} = m_2 h_2 - m_1 h_1 + (P_1 - P_2)V + m_e h_{e\ AVE}$

Let $h_1^* = 0$ then $h_1 = 0 + (h_1 - h_1^*) = -62.8$

$h_2 = h_1^* + (h_2^* - h_1^*) + (h_2 - h_2^*) = 0 - 158.7 - 55.3 = -214.0$

$h_{e\ AVE} = (h_1 + h_2)/2 = -138.4$

$Q_{CV} = 6.275(-214.0) - 12.55(-62.8)$

$+ (3500\text{-}1326) \times 0.2 + 6.275(-138.4) =$ **-981.4 kJ**

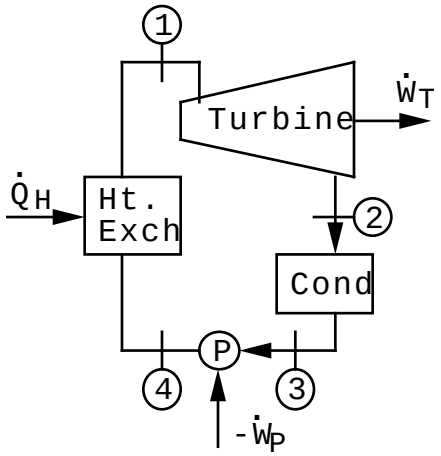
12.143

One kilogram per second water enters a solar collector at 40°C and exits at 190°C, as shown in Fig. P12.143. The hot water is sprayed into a direct-contact heat exchanger (no mixing of the two fluids) used to boil the liquid butane. Pure saturated-vapor butane exits at the top at 80°C and is fed to the turbine. If the butane condenser temperature is 30°C and the turbine and pump isentropic efficiencies are each 80%, determine the net power output of the cycle.

H_2O cycle: solar energy input raises 1 kg/s of liquid H_2O from 40°C to 190°C. Therefore, corresponding heat input to the butane in the heat exchanger is

$$\dot{Q}_H = \dot{m}(h_{F\ 190\ C} - h_{F\ 40\ C})_{H2O} = 1(807.62 - 167.57) = 640.05 \text{ kW}$$



C_4H_{10} cycle

$T_1 = 80\ ^oC,\ x_1 = 1.0\ ;\ T_3 = 30\ ^oC,\ x_3 = 0.0$

$\eta_{ST} = \eta_{SP} = 0.80$

$$T_{r1} = \frac{353.2}{425.2} = 0.831$$

From D.1, D.2 and D.3:

$P_1 = 0.325 \times 3800 = 1235$ kPa

$(h_1^* - h_1) = 0.143\ 04 \times 425.2 \times 0.56 = 34.1$

$(s_1^* - s_1) = 0.143\ 04 \times 0.475 = 0.0680$

$$T_{r3} = \frac{303.2}{425.2} = 0.713$$

From D.1, D.2 and D.3: $P_3 = 0.113 \times 3800 = 429$ kPa

sat. liq.: $(h^* - h_F) = RT_C \times 4.81 = 292.5$; $(s^* - s_F) = R \times 6.64 = 0.950$

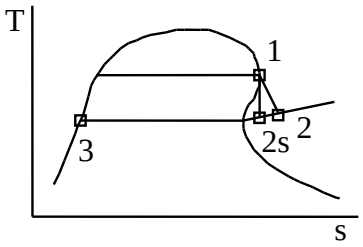
sat. vap.: $(h^* - h_G) = RT_C \times 0.235 = 14.3$; $(s^* - s_G) = R \times 0.22 = 0.031$

Because of the combination of properties of C_4H_{10} (particularly the large C_{P0}/R), s_1 is larger than s_G at T_3. To demonstrate,

$$(s_1^* - s_{G3}^*) = 1.7164 \ln\frac{353.2}{303.2} - 0.143\ 04 \ln\frac{1235}{429} = 0.1107$$

$(s_1 - s_{G3}) = -0.0680 + 0.1107 + 0.031 = +0.0737$ kJ/kg K

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*



so that T_{2S} will be $> T_3$, as shown in the T-s diagram. A number of other heavy hydrocarbons also exhibit this behavior.
Assume $T_{2S} = 315$ K, $T_{r2S} = 0.741$

From D.2 and D.3:

$$(h^*_{2S}-h_{2S}) = RT_C\times 0.21 = 12.8 \quad \text{and} \quad (s^*_{2S}-s_{2S}) = R\times 0.19 = 0.027$$

$$(s^*_1-s^*_{2S}) = 1.7164 \ln\frac{353.2}{315} - 0.143\,04 \ln\frac{1235}{429} = +0.0453$$

$$(s_1-s_{2S}) = -0.0680 + 0.0453 + 0.027 \approx 0$$

$$\Rightarrow T_{2S} = 315 \text{ K}$$

$$(h^*_1-h^*_{2S}) = 1.7164(353.2-315) = 65.6$$

$$w_{ST} = h_1-h_{2S} = -34.1 + 65.6 + 12.8 = 44.3 \text{ kJ/kg}$$

$$w_T = \eta_S\times w_{ST} = 0.80\times 44.3 = 35.4 \text{ kJ/kg}$$

At state 3,

$$v_3 = \frac{0.019\times 0.143\,04\times 303.2}{429} = 0.001\,92 \text{ m}^3/\text{kg}$$

$$-w_{SP} \approx v_3(P_4-P_3) = 0.001\,92(1235-429) = 1.55 \text{ kJ/kg}$$

$$-w_P = \frac{-w_{SP}}{\eta_{SP}} = \frac{1.55}{0.8} = 1.94 \text{ kJ/kg}$$

$$w_{NET} = w_T + w_P = 35.4 - 1.94 = 33.46 \text{ kJ/kg}$$

For the heat exchanger,

$$\dot{Q}_H = 640.05 = \dot{m}_{C4H10}(h_1-h_4)$$

But $h_1-h_4 = h_1-h_3+w_P$

$$h_1-h_3 = (h_1-h^*_1) + (h^*_1-h^*_3) + (h^*_3-h_3)$$

$$= -34.1 + 1.716(80 - 30) + 292.5 = 344.2 \text{ kJ/kg}$$

Therefore,

$$\dot{m}_{C4H10} = \frac{640.05}{344.2-1.94} = 1.87 \text{ kg/s}$$

$$\dot{W}_{NET} = \dot{m}_{C4H10}w_{NET} = 1.87 \times 33.46 = \mathbf{62.57\ kW}$$

12.144

A piston/cylinder contains ethane gas, initially at 500 kPa, 100 L, and at ambient temperature, 0°C. The piston is now moved, compressing the ethane until it is at 20°C, with a quality of 50%. The work required is 25% more than would have been required for a reversible polytropic process between the same initial and final states. Calculate the heat transfer and the entropy generation for the process.

Ethane: $T_c = 305.4$ K, $P_c = 4.88$ MPa,

$R = 0.2765$ kJ/kg-K, $C_p = 1.766$ kJ/kg K

State 1: $T_{r1} = 0.895$, $P_{r1} = 0.102 \rightarrow Z_1 = 0.95$

$v_1 = Z_1 RT_1/P_1 = 0.1435$ m^3/kg, $m_1 = V_1/v_1 = 0.697$ kg

$(h_1^* - h_1) = 0.13RT_c = 11.0$ kJ/kg, $(s_1^* - s_1) = 0.09\ R = 0.025$ kJ/kg K

State 2: $T_2 = 20^oC$, $x_2 = 0.5$, ${}_1W_2 = 1.25W_{rev}$

$T_{r2} = 0.96$, $P_{r2} = 0.78$, $P_2 = P_{r2}P_c = 3806$ kPa

$Z_{f2} = 0.14$, $Z_{g2} = 0.54$, $Z_2 = (1 - x_2)Z_f + x_2 Z_g = 0.34$

$(h_2^* - h_2) = (1 - x_2)\ 3.65\ RT_c + x_2\ (1.39\ RT_c) = 212.8$ kJ/kg

$(s_2^* - s_2) = (1 - x_2)\ 3.45\ R + x_2 \times 1.10\ R = 0.629$ kJ/kg K

$v_2 = Z_2 RT_2/P_2 = 0.0072$ m^3/kg, $V_2 = mv_2 = 0.005$ m^3

Polytropic process

$$P_1V_1^n = P_2V_2^n, \quad \ln\frac{P_2}{P_1} = n \ln\frac{V_1}{V_2} \rightarrow n = 0.6783$$

$$W_{rev} = \int P\, dV = \frac{P_2V_2 - P_1V_1}{1 - n} = -96.3 \text{ kJ},$$

$${}_1W_2 = 1.25W_{rev} = -120.4 \text{ kJ}$$

a) Energy Eq.: ${}_1Q_2 = m(u_2 - u_1) + {}_1W_2$; $u = h - Pv$

$$h_2 - h_1 = (h_2 - h_2^*) + (h_2^* - h_1^*) + (h_1^* - h_1)$$

$$= -212.8 + 1.766(20 - 0) + 11.0 = -166.5 \text{ kJ/kg}$$

$$u_2 - u_1 = (h_2 - h_1) - (P_2v_2 - P_1v_1) = -122.2 \text{ kJ/kg}$$

${}_1Q_2 = 0.697$ kg (-122.2) kJ/kg - 120.4 kJ = **-205.6 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

b) Entropy Eq.: $S_{gen} = m(s_2 - s_1) - {}_1Q_2 / T_o$; $T_o = 0^oC = 273.15$ K

$s_2 - s_1 = (s_2 - s_2^*) + (s_2^* - s_1^*) + (s_1^* - s_1)$

$(s_2^* - s_1^*) = C_p \ln(T_2 / T_1) - R \ln(P_2 / P_1) = -0.436$ kJ/kg K,

$S_{gen} = 0.697(-0.629 - 0.436 + 0.025) + \frac{205.6}{273.15} =$ **0.028 kJ/K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.145

Carbon dioxide gas enters a turbine at 5 MPa, 100°C, and exits at 1 MPa. If the isentropic efficiency of the turbine is 75%, determine the exit temperature and the second-law efficiency using the generalized charts.

CO_2 turbine: $\eta_S = w/w_S = 0.75$

inlet: $T_1 = 100^oC$, $P_1 = 5$ MPa, exhaust: $P_2 = 1$ MPa

a) $P_{r1} = \frac{5}{7.38} = 0.678$, $T_{r1} = \frac{373.2}{304.1} = 1.227$, $P_{r2} = \frac{1}{7.38} = 0.136$

From D.2 and D.3,

$(h_1^* - h_1) = 0.188\ 92 \times 304.1 \times 0.52 = 29.9$

$(s_1^* - s_1) = 0.188\ 92 \times 0.30 = 0.0567$

Assume $T_{2S} = 253$ K, $T_{r2S} = 0.832$

From D.2 and D.3: $(h_{2S}^* - h_{2S}) = RT_C \times 0.20 = 11.5$

$(s_{2S}^* - s_{2S}) = R \times 0.17 = 0.0321$

$(s_{2S}^* - s_1^*) = 0.8418 \ln \frac{253}{373.2} - 0.188\ 92 \ln \frac{1}{5} = -0.0232$

$(s_{2S} - s_1) = -0.0321 - 0.0232 + 0.0567 \approx 0$

$\Rightarrow T_{2S} = 253$ K

$(h_{2S}^* - h_1^*) = 0.8418(253 - 373.2) = -101.2$

$w_S = (h_1 - h_{2S}) = -29.9 + 101.2 + 11.5 = 82.8$ kJ/kg

$w = \eta_S \times w_S = 0.75 \times 82.8 = 62.1$ kJ/kg $= (h_1 - h_1^*) + (h_1^* - h_2^*) + (h_2^* - h_2)$

Assume $T_2 = 275$ K, $T_{r2} = 0.904$

$(h_1^* - h_2^*) = 0.8418\ (373.2 - 275) = 82.7$

From D.2 and D.3,

$(h_2^* - h_2) = RT_C \times 0.17 = 9.8$; $(s_2^* - s_2) = R \times 0.13 = 0.0245$

Substituting,

$w = -29.9 + 82.7 + 9.8 = 62.7 \approx 62.1$ $\Rightarrow T_2 =$ **275 K**

For the exergies we need the entropy changes

12.146

A 10- m^3 storage tank contains methane at low temperature. The pressure inside is 700 kPa, and the tank contains 25% liquid and 75% vapor, on a volume basis. The tank warms very slowly because heat is transferred from the ambient.

a. What is the temperature of the methane when the pressure reaches 10 MPa?

b. Calculate the heat transferred in the process, using the generalized charts.

c. Repeat parts (a) and (b), using the methane tables, Table B.7. Discuss the differences in the results.

CH_4: $V = 10\ m^3$, $P_1 = 700$ kPa

$V_{LIQ\,1} = 2.5\ m^3$, $V_{VAP\,1} = 7.5\ m^3$

a) $P_{r1} = \dfrac{0.70}{4.60} = 0.152$, $P_{r2} = \dfrac{10}{4.60} = 2.174$

From D.1: $Z_{F1} = 0.025$, $Z_{G1} = 0.87$ &

$T_1 = 0.74 \times 190.4 = 140.9$ K

$$v_{F1} = \frac{0.025 \times 0.5183 \times 140.9}{700} = 0.00261$$

$$v_{G1} = \frac{0.87 \times 0.5183 \times 140.9}{700} = 0.0908$$

$$m_{LIQ\,1} = \frac{2.5}{0.00261} = 957.9 \text{ kg}, \quad m_{VAP\,1} = \frac{7.5}{0.0908} = 82.6 \text{ kg}$$

Total m = 1040.3 kg

$$v_2 = v_1 = \frac{V}{m} = \frac{10}{1040.5} = 0.00961 = \frac{Z_2 \times 0.5183 \times 190.4 \times T_{r2}}{10\,000}$$

or $Z_2 T_{r2} = 0.9737$ at $P_{r2} = 2.174$

By trial and error

$T_{r2} = 1.334$ & $Z_2 = 0.73$, $T_2 = 1.334 \times 190.4 =$ **254.0 K**

b) Energy Eq.:

$$Q_{12} = m(u_2 - u_1) = m(h_2 - h_1) - V(P_2 - P_1)$$

Using D.2 & $x_1 = \dfrac{82.6}{1040.5} = 0.0794$

$$(h_1^* - h_1) = (h_1^* - h_{f1}) - x_1 h_{fg1}$$

$$= 0.518\,35 \times 190.4 \left[4.72 - 0.0794(4.72 - 0.29) \right] = 431.1$$

$$(h_2^* - h_1^*) = C_P (T_2 - T_1) = 2.254\ (254.0 - 140.9) = 254.9$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$(h_2^* - h_2) = 0.5183 \times 190.4(1.47) = 145.1$

$(h_2 - h_1) = -145.1 + 254.9 + 431.1 = 540.9$ kJ/kg

$Q_{12} = 1040.5$ kg (540.9) kJ/kg – 10 m^3 (10 000-700) kPa

= **469 806 kJ**

c) Using Table B.7 for CH_4

$T_1 = T_{SAT\,1} = 141.7$ K, $v_{F1} = 0.002\,675$, $u_{F1} = -178.47$

$v_{G1} = 0.090\,45$, $u_{G1} = 199.84$

$$m_{LIQ\,1} = \frac{2.5}{0.002\,675} = 934.6, \qquad m_{VAP\,1} = \frac{7.5}{0.090\,45} = 82.9$$

Total mass m = 1017.5 kg and $v_2 = \frac{10}{1017.5} = 0.009\,828$ m^3/kg

$$\text{At } v_2 \text{ \& } P_2 = 10 \text{ MPa} \rightarrow \begin{cases} T_2 = 259.1 \text{ K} \\ u_2 = 296.11 \end{cases}$$

$Q_{12} = m(u_2 - u_1) = 1017.5 \times 296.11 - 934.6(-178.47) - 82.9(199.84)$

= **451 523 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.147

Consider the following reference state conditions: the entropy of real saturated liquid methane at −100°C is to be taken as 100 kJ/kmol K, and the entropy of hypothetical ideal gas ethane at −100°C is to be taken as 200 kJ/kmol K. Calculate the entropy per kmol of a real gas mixture of 50% methane, 50% ethane (mole basis) at 20°C, 4 MPa, in terms of the specified reference state values, and assuming Kay's rule for the real mixture behavior.

CH_4: T_0 = -100 °C, $\bar{s}_{LIQ\,0}$ = 100 kJ/kmol K

C_2H_6: T_0 = -100 °C, P_0 = 1 MPa, $\bar{s}^*_0$ = 200 kJ/kmol K

Also for CH_4: T_C = 190.4 K, P_C = 4.60 MPa

For a 50% mixture Kay's rule Eq.12.84:

$$T_{cmix} = 0.5 \times 190.4 + 0.5 \times 305.4 = 247.9 \text{ K}$$

$$P_{cmix} = 0.5 \times 4.60 + 0.5 \times 4.88 = 4.74 \text{ MPa}$$

IG MIX at T_0(=-100 °C), P_0(=1 MPa):

CH_4: $T_{r0} = 0.91$, $P_G = 0.57 \times 4.60 = 2.622$ MPa

$$\bar{s}^*_{0\,CH4} = \bar{s}_{LIQ\,0\,P_G} + (\bar{s}^* - \bar{s}_{LIQ})_{at\,P_G} - \bar{R} \ln (P_0/P_G)$$

$$= 100 + 4.01 \times 8.3145 - 8.3145 \ln (1/2.622) = 141.36$$

$$\bar{s}^*_{0\,MIX} = 0.5 \times 141.36 + 0.5 \times 200 - 8.3145(0.5 \ln 0.5 + 0.5 \ln 0.5) = 176.44$$

$$\bar{C}_{P0\,MIX} = 0.5 \times 16.04 \times 2.254 + 0.5 \times 30.07 \times 1.766 = 44.629$$

$$\bar{s}^*_{TP\,MIX} = 176.44 + 44.629 \ln \frac{293.2}{173.2} - 8.3145 \ln \frac{4}{1} = 188.41 \text{ kJ/kmol K}$$

For the mixture at T, P: T_r = 1.183, P_r = 0.844

Entropy departure $\bar{s}^*_{TP\,MIX} - \bar{s}_{TP\,MIX} = 0.4363 \times 8.3145 = 3.63$ kJ/kmol K

Therefore,

$$\bar{s}_{TP\,MIX} = 188.41 - 3.63 = \mathbf{184.78 \text{ kJ/kmol K}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

An alternative is to form the ideal gas mixture at T, P instead of at T_0, P_0 :

$$\bar{s}^*_{TP\ CH4} = \bar{s}_{LIQ\ 0} + (\bar{s}^* - \bar{s}_{LIQ}) + \bar{C}_{P0\ CH4} \ln\frac{T}{T_0} - \bar{R} \ln\frac{P}{P_G}$$

P_G, T_0 at P_G, T_0

$$= 100 + 33.34 + 16.04 \times 2.254 \ln\frac{293.2}{173.2} - 8.3145 \ln\frac{4}{2.6}$$

$$= 100 + 33.34 + 19.03 - 3.53 = 148.84 \text{ kJ/kmol K}$$

$$\bar{s}^*_{TP\ C2H6} = 200 + 30.07 \times 1.766 \ln\frac{293.2}{173.2} - 8.3145 \ln\frac{4}{1}$$

$$= 200 + 27.96 - 11.53 = 216.43 \text{ kJ/kmol K}$$

$$\bar{s}^*_{TP\ MIX} = 0.5 \times 148.84 + 0.5 \times 216.43$$

$$- 8.3145(0.5 \ln 0.5 + 0.5 \ln 0.5) = 188.41 \text{ kJ/kmol K}$$

$$\bar{s}_{TP\ MIX} = 188.41 - 3.63 = \mathbf{184.78\ kJ/kmol\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.148

Determine the heat transfer and the net entropy change in problem 12.129. Use the initial pressure of the carbon dioxide to be 4.56 MPa before the ethylene is flowing into the tank.

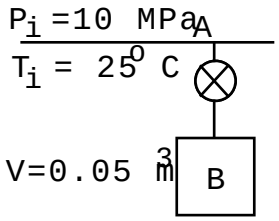
A gas mixture of a known composition is frequently required for different purposes, e.g., in the calibration of gas analyzers. It is desired to prepare a gas mixture of 80% ethylene and 20% carbon dioxide (mole basis) at 10 MPa, 25°C in an uninsulated, rigid 50-L tank. The tank is initially to contain CO2 at 25°C and some pressure *P*1. The valve to a line flowing C2H4 at 25°C, 10 MPa, is now opened slightly, and remains open until the tank reaches 10 MPa, at which point the temperature can be assumed to be 25°C. Assume that the gas mixture so prepared can be represented by Kay's rule and the generalized charts. Given the desired final state, what is the initial pressure of the carbon dioxide, *P*1?

$A = C_2H_4$, $B = CO_2$

$T_1 = 25\ ^oC$

$P_2 = 10$ MPa, $T_2 = 25\ ^oC$

$y_{A2} = 0.8$, $y_{B2} = 0.2$



Mixture at 2 :

$P_{C2} = 0.8 \times 5.04 + 0.2 \times 7.38 = 5.508$ MPa

$T_{C2} = 0.8 \times 282.4 + 0.2 \times 304.1 = 286.7$ K

$T_{r2} = 298.15/286.7 = 1.040$; $P_{r2} = 10/5.508 = 1.816$

D.1 : $Z_2 = 0.32$

$$n_2 = \frac{P_2 V}{Z_2 \bar{R} T_2} = \frac{10\,000 \times 0.05}{0.32 \times 8.3145 \times 298.2} = 0.6302 \text{ kmol}$$

$n_{A2} = n_i = 0.8\ n_2 = 0.5042$ kmol C_2H_4

$n_{B2} = n_1 = 0.2\ n_2 = 0.1260$ kmol CO_2

$$T_{r1} = \frac{298.2}{304.1} = 0.981 \quad \text{and} \quad P_{r1} = \frac{4560}{7380} = 0.618$$

Energy Eq.: $Q_{CV} + n_i \bar{h}_i = n_2 \bar{u}_2 - n_1 \bar{u}_1 = n_2 \bar{h}_2 - n_1 \bar{h}_1 - (P_2 - P_1)V$

or $Q_{CV} = n_2(\bar{h}_2 - \bar{h}_2^*) - n_1(\bar{h}_1 - \bar{h}_1^*) - n_i(\bar{h}_i - \bar{h}_i^*) - (P_2 - P_1)V$

(since $T_i = T_1 = T_2$, $\bar{h}_i^* = \bar{h}_1^* = \bar{h}_2^*$)

$(\bar{h}_1^* - \bar{h}_1) = 0.83 \times 8.3145 \times 304.1 = 2099$ kJ/kmol

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$(\bar{h}_2^* - \bar{h}_2) = 3.40 \times 8.3145 \times 286.7 = 8105$ kJ/kmol

$T_{ri} = \frac{298.2}{282.4} = 1.056$, $P_{ri} = \frac{10}{5.04} = 1.984$

$(\bar{h}_i^* - \bar{h}_i) = 3.35 \times 8.3145 \times 282.4 = 7866$ kJ/kmol

$Q_{CV} = 0.6302(-8105) - 0.126(-2099) - 0.5042(-7866) - (10\,000 - 4560) \times 0.05$

$= \mathbf{-1149\ kJ}$

$\Delta S_{CV} = n_2 \bar{s}_2 - n_1 \bar{s}_1$, $\Delta S_{SURR} = - Q_{CV}/T_0 - n_i \bar{s}_i$

$\Delta S_{gen} = n_2 \bar{s}_2 - n_1 \bar{s}_1 - Q_{CV}/T_0 - n_i \bar{s}_i$

Let $\bar{s}_{A0}^* = \bar{s}_{B0}^* = 0$ at $T_0 = 25\ ^oC$, $P_0 = 0.1$ MPa

Then $\bar{s}_{MIX\ 0}^* = -8.3145\ (0.8 \ln 0.8 + 0.2 \ln 0.2) = 4.161$ kJ/kmol K

$\bar{s}_1 = \bar{s}_{B0}^* + (\bar{s}_{P1\ T1}^* - \bar{s}_{P0\ T0}^*)_B + (\bar{s}_1 - \bar{s}_{P1\ T1}^*)_B$

$= 0 + (0 - 8.3145 \ln \frac{4.56}{0.1}) - 0.60 \times 8.3145 = -36.75$ kJ/kmol K

$\bar{s}_i = \bar{s}_{A0}^* + (\bar{s}_{Pi\ Ti}^* - \bar{s}_{P0\ T0}^*)_A + (\bar{s}_i - \bar{s}_{Pi\ Ti}^*)_A$

$= 0 + (0 - 8.3145 \ln \frac{10}{0.1}) - 2.44 \times 8.3145 = -58.58$ kJ/kmol K

$\bar{s}_2 = \bar{s}_{MIX\ 0}^* + (\bar{s}_{P2\ T2}^* - \bar{s}_{P0\ T0}^*)_{MIX} + (\bar{s}_2 - \bar{s}_{P2\ T2}^*)_{MIX}$

$= 4.161 + (0 - 8.3145 \ln \frac{10}{0.1}) - 2.551 \times 8.3145 = -55.34$ kJ/kmol K

$S_{gen} = 0.6302(-55.33) - 0.126(-36.75) - 0.5042(-58.58) + 1149/298.2$

$= \mathbf{+3.15\ kJ/K}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Clapeyron Equation

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.149E

Verify that Clapeyrons equation is satisfied for R-410A at 30 F in Table F.9.

Clapeyron Eq.: $$\frac{dP_{sat}}{dT} = \frac{dP_g}{dT} = \frac{h_{fg}}{Tv_{fg}}$$

F.9: $P = 111.796$ psia, $h_{fg} = 95.75$ Btu/lbm, $v_{fg} = 0.5289$ ft^3/lbm

Slope around 30 F best approximated by cord from 20 F to 40 F

$$\frac{dP_g}{dT} = \frac{133.163 - 93.128}{40 - 20} = 2.00 \text{ psia/R},$$

$$\frac{h_{fg}}{Tv_{fg}} = \frac{95.75}{489.7 \times 0.5289} \frac{778}{144} = 1.997 \text{ psia/R}$$

This fits very well.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.150E

Use the approximation given in Problem 12.16 and Table F.7 to determine A and B for steam from properties at 70 F only. Use the equation to predict the saturation pressure at 80 F and compare to table value.

$$\ln P_{sat} = A - B/T \qquad \Rightarrow \qquad \frac{dP_{sat}}{dT} = P_{sat}\,(-B)(-T^{-2})$$

so we notice from Eq.12.7 and Table values from F.7.1 and F.4 that

$$B = \frac{h_{fg}}{R} = \frac{1053.95}{85.76 / 778} = 9561.3\ R$$

Now the constant A comes from the saturation pressure as

$$A = \ln P_{sat} + B/T = \ln 0.363 + \frac{9561.3}{459.67 + 70} = 17.038$$

Use the equation to predict the saturation pressure at 80 F as

$$\ln P_{sat} = A - B/T = 17.038 - \frac{9561.3}{459.67 + 80} = -0.6789$$

$$P_{sat} = 0.5071\ \text{psia}$$

compare this with the table value of $P_{sat} = 0.507$ psia and we have a very accurate approximation.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.151E

Find the saturation pressure for refrigerant R-410A at –100 F assuming it is higher than the triple point temperature.

The lowest temperature in Table F.9 for R-410A is -80 F, so it must be extended to -100 F using the Clapeyron Eq. 12.7 integrated as in example 12.1

At T_1 = -80 F = 379.7 R ,

P_1 = 8.196 lbf/in.^{2} and $R = \frac{1.9859}{72.585}$ = 0.027 36 Btu/lbm R

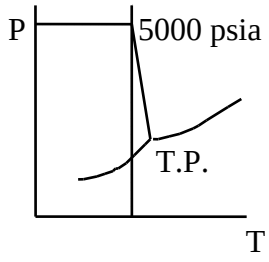
$$\ln \frac{P}{P_1} = \frac{h_{fg}}{R} \frac{(T-T_1)}{T \times T_1} = \frac{121.14}{0.027\ 36} \frac{(359.7-379.7)}{359.7 \times 379.7} = -0.6484$$

$P = P_1 \exp(-0.6484) =$ **4.286 lbf/in.^{2}**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.152E

Using thermodynamic data for water from Tables F.7.1 and F.7.3, estimate the freezing temperature of liquid water at a pressure of 5000 lbf/in.^{2}.



H_2O $\quad \dfrac{dP_{if}}{dT} = \dfrac{h_{if}}{Tv_{if}} \approx$ constant

At the triple point,

$v_{if} = v_f - v_i = 0.016\,022 - 0.017\,473$

$= -0.001\,451$ ft^3/lbm

$h_{if} = h_f - h_i = 0.0 - (-143.34) = 143.34$ Btu/lbm

$$\frac{dP_{if}}{dT} = \frac{143.34}{491.69(-0.001\,451)} \times \frac{778.2}{144} = -1085.8 \text{ lbf/in.}^2 \text{ R}$$

$\Rightarrow$ at P = 5000 lbf/in^2,

$$T \approx 32.02 + \frac{(5000-0.09)}{(-1085.8)} = \mathbf{27.4\ F}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.153E

Ice (solid water) at 27 F, 1 atm is compressed isothermally until it becomes liquid. Find the required pressure.

Water, triple point T = 32.02 F = 491.69 R, P = 0.088 67 lbf/in.^{2}

v_f = 0.016 022 ft^3/lbm, v_i = 0.017 473 ft^3/lbm

h_f = 0.00 Btu/lbm h_i = -143.34 Btu/lbm

Clapeyron $$\frac{dP_{if}}{dT} = \frac{h_f - h_i}{(v_f - v_i)T} = \frac{143.34 \times 778.2}{-0.001\,451 \times 491.69 \times 144} = -1085.8 \text{ psia/R}$$

$$\Delta P \approx \frac{dP_{if}}{dT}\Delta T = -1085.8\,(27 - 32.02) = 5450.7 \text{ lbf/in.}^2$$

$$P = P_{tp} + \Delta P = \mathbf{5451 \text{ lbf/in.}^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Volume Expansivity and Compressibility

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.154E

Determine the volume expansivity, α_P, and the isothermal compressibility, β_T, for water at 50 F, 500 lbf/in.^{2} and at 400 F, 1500 lbf/in.^{2} using the steam tables.

Water at 50 F, 500 lbf/in.^{2} (compressed liquid)

$$\alpha_P = \frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_P \approx \frac{1}{v}\left(\frac{\Delta v}{\Delta T}\right)_P$$

Using values at 32 F, 50 F and 100 F

$$\alpha_P \approx \frac{1}{0.015\ 99}\frac{0.016\ 1 - 0.015\ 99}{100 - 32} = \mathbf{0.000\ 101\ F^{-1}}$$

$$\beta_T = -\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_T \approx -\frac{1}{v}\left(\frac{\Delta v}{\Delta P}\right)_T$$

Using values at saturation, 500 and 1000 lbf/in.^{2}

$$\beta_T \approx -\frac{1}{0.015\ 99}\frac{0.015\ 99 - 0.016\ 02}{1000 - 0.178} = \mathbf{0.000\ 0019\ in.^2/lbf}$$

Water at 400 F, 1500 lbf/in.^{2} (compressed liquid)

$$\alpha_P \approx \frac{1}{0.018\ 45}\frac{0.019\ 25 - 0.017\ 85}{450 - 350} = \mathbf{0.000\ 76\ F^{-1}}$$

$$\beta_T \approx -\frac{1}{0.018\ 45}\frac{0.0184 - 0.0185}{2000 - 1000} = \mathbf{0.000\ 0054\ in.^2/lbf}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.155E

Use the CATT3 software to solve the previous problem.

The benefit of the software to solve for the partial derivatives is that we can narrow the interval over which we determine the slope.

Water at 50 F, 500 lbf/in.^{2} (compressed liquid)

$$\alpha_P = \frac{1}{v}\left(\frac{\partial v}{\partial T}\right)_P \approx \frac{1}{v}\left(\frac{\Delta v}{\Delta T}\right)_P \quad ; \quad \beta_T = -\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_T \approx -\frac{1}{v}\left(\frac{\Delta v}{\Delta P}\right)_T$$

Estimate by finite difference using values at 40 F, 50 F and 60 F,

$$\alpha_P \approx \frac{1}{0.01600}\frac{0.01601 - 0.01599}{60 - 40} = \mathbf{0.000\ 0625\ F^{-1}}$$

Using values at saturation, 500 psia and 1000 psia,

$$\beta_T \approx -\frac{1}{0.0160}\frac{0.01597 - 0.01602}{1000 - 0.178} = \mathbf{0.000\ 0031\ psi^{-1}}$$

Water at 400 F, 1500 lbf/in.^{2} (compressed liquid)

Estimate by finite difference using values at 350 F, 400 F and 450 F,

$$\alpha_P \approx \frac{1}{0.01\ 849}\frac{0.019\ 26 - 0.017\ 86}{450 - 350} = \mathbf{0.000\ 757\ F^{-1}}$$

Using values at 1000 psia, 1500 psia and 2000 psia,

$$\beta_T \approx -\frac{1}{0.018\ 49}\frac{0.01\ 844 - 0.01\ 855}{2000 - 1000} = \mathbf{0.000\ 0059\ psi^{-1}}$$

12.156E

A cylinder fitted with a piston contains liquid methanol at 70 F, 15 lbf/in.^{2} and volume 1 ft^3. The piston is moved, compressing the methanol to 3000 lbf/in.^{2} at constant temperature. Calculate the work required for this process. The isothermal compressibility of liquid methanol at 70 F is 8.3×10^{-6} in.^{2}/lbf.

$$ {}_1w_2 = \int_1^2 P dv = \int P \left(\frac{\partial v}{\partial P}\right)_T dP_T = -\int_1^2 v\beta_T P dP_T $$

For $v \approx$ const & $\beta_T \approx$ const. $\Rightarrow$ $ {}_1w_2 = -\frac{v\beta_T}{2}\left(P_2^2 - P_1^2\right) $

For liquid methanol, from Table F.3 : $\rho = 49.1$ lbm/ft^3

$V_1 = 1.0$ ft^3, $m = 1.0 \times 49.1 = 49.1$ lbm

$$ {}_1W_2 = \frac{1.0 \times 8.3 \times 10^{-6}}{2}\left[(3000)^2 - (15)^2\right] \times 144 = 5378.4 \text{ ft lbf} = \mathbf{6.9\ Btu} $$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.157E

Sound waves propagate through a media as pressure waves that causes the media to go through isentropic compression and expansion processes. The speed of sound c is defined by $c^2 = (\partial P/\partial \rho)_s$ and it can be related to the adiabatic compressibility, which for liquid ethanol at 70 F is 6.4×10^{-6} in.^{2}/lbf. Find the speed of sound at this temperature.

$$c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s = \frac{1}{-\frac{1}{v}\left(\frac{\partial v}{\partial P}\right)_s \rho} = \frac{1}{\beta_s \rho}$$

From Table F.3 for ethanol, $\rho = 48.9$ lbm/ft^3

$$\Rightarrow c = \left(\frac{32.174 \times 144}{6.4 \times 10^{-6} \times 48.9}\right)^{1/2} = \mathbf{3848\ ft/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.158E

Consider the speed of sound as defined in Eq. 12.42. Calculate the speed of sound for liquid water at 50 F, 250 lbf/in.^{2} and for water vapor at 400 F, 80 lbf/in.^{2} using the steam tables.

From Eq 12.42 : $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s$

Liquid water at 50 F, 250 lbf/in.^{2}

Assume $\left(\frac{\partial P}{\partial v}\right)_s \approx \left(\frac{\Delta P}{\Delta v}\right)_T$

Using saturated liquid at 50 F and compressed liquid at 50 F, 500 lbf/in.^{2},

$$c^2 = -\left(\frac{0.016024+0.015998}{2}\right)^2\left(\frac{(500-0.18)\times 144\times 32.174}{0.015998-0.016024}\right) = 22.832\times 10^6$$

c = **4778 ft/s**

Superheated vapor water at 400 F, 80 lbf/in.^{2}

$v = 6.217$ ft^3/lbm, $s = 1.6790$ Btu/lbm R

At P = 60 lbf/in.^{2} & s = 1.6790: T = 343.8 F, v = 7.7471 ft^3/lbm

At P = 100 lbf/in.^{2} & s = 1.6790: T = 446.2 F, v = 5.2394 ft^3/lbm

$$c^2 = -(6.217)^2\left(\frac{(100-60)\times 144\times 32.174}{5.2394-7.7471}\right) = 2.856 \times 10^6$$

c = **1690 ft/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.159E

Liquid methanol at 77 F has an adiabatic compressibility of 7.1×10^{-6} in^2/lbf. What is the speed of sound? If it is compressed from 15 psia to 1500 psia in an insulated piston/cylinder, what is the specific work?

From Eq.12.41 and Eq.12.42 and the density from table F.3

$$c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s = \frac{1}{\beta_s \rho} = \frac{1}{7.1 \times 10^{-6} \times 49.1} 144 \times 32.174 \text{ ft}^2/\text{s}^2$$

$$= 13.290 \times 10^6 \text{ ft}^2/\text{s}^2$$

$$c = \mathbf{3645 \text{ ft/s}}$$

The specific work becomes

$$w = \int P\, dv = \int P\, (-\beta_s v)\, dP = -\int \beta_s v\, P\, dP = -\beta_s\, v \int_1^2 P\, dP$$

$$= -\beta_s\, v\, 0.5\, (P_2^2 - P_1^2)$$

$$= -7.1 \times 10^{-6} \text{ in}^2/\text{lbf} \times \frac{0.5}{49.1} \text{ ft}^3/\text{lbm} \times (1500^2 - 15^2) \text{ psi}^2$$

$$= -0.163 \text{ (ft-lbf/lbm) (ft/in)}^2 = \mathbf{-23.4 \text{ ft-lbf/lbm} = -0.03 \text{ Btu/lbm}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Equations of State

12.160E

Use Table F.9 to find the compressibility of R-410A at 140 F and a) saturated liquid b) saturated vapor and c) 400 psia

.

Table F.1: R = 1545.36 / 72.585 = 21.29 lbf-ft/lbm-R

a) Table F.9.1: P = 556.488 psia, v = 0.01966 ft^3/lbm

$$Z = \frac{Pv}{RT} = \frac{556.488 \times 0.01966 \times 144}{21.29 \times 599.7} = \mathbf{0.1234}$$

b) Table F.9.1: P = 556.488 psia, v = 0.0796 ft^3/lbm

$$Z = \frac{Pv}{RT} = \frac{556.488 \times 0.0796 \times 144}{21.29 \times 599.7} = \mathbf{0.5}$$

c) Table F.9.2: P = 400 psia, v = 0.1574 ft^3/lbm

$$Z = \frac{Pv}{RT} = \frac{400 \times 0.1574 \times 144}{21.29 \times 599.7} = \mathbf{0.71}$$

The R-410A is not an ideal gas at any of these states.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.161E

Calculate the difference in internal energy of the ideal-gas value and the real-gas value for carbon dioxide at the state 70 F, 150 lbf/in.^{2}, as determined using the virial EOS. At this state B = -2.036 ft^3/lb mol, T(dB/dT) = 4.236 ft^3/lb mol.

Solution: CO_2 at 70 F, 150 lbf/in^2

virial: $P = \frac{RT}{v} + \frac{BRT}{v^2}$; $\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v} + \frac{BR}{v^2} + \frac{RT}{v^2}\left(\frac{dB}{dT}\right)$

$$u-u^* = -\int_v^\infty \left[T\left(\frac{\partial P}{\partial T}\right)_v - P\right]dv = -\int_v^\infty \frac{RT^2}{v^2}\left(\frac{dB}{dT}\right) dv = -\frac{RT^2}{v}\frac{dB}{dT}$$

$B = -2.036$ ft^3/lbmol $\quad T\left(\frac{dB}{dT}\right) = 4.236$ ft^3/lbmol

Solution of virial equation (quadratic formula):

$$\bar{v} = \frac{1}{2}\frac{\bar{R}T}{P}\left[1 + \sqrt{1+4BP/\bar{R}T}\right]$$

But $\frac{\bar{R}T}{P} = \frac{1545\times 529.7}{150\times 144} = 37.8883$

$$\bar{v} = 0.5\times 37.8883\left[1 + \sqrt{1+4(-2.036)/37.8883}\right] = 35.7294 \text{ ft}^3\text{/lbmol}$$

Using the minus-sign root of the quadratic formula results in a compressibility factor < 0.5, which is not consistent with such a truncated equation of state.

$$\bar{u} - \bar{u}^* = -\frac{RT}{v} T\frac{dB}{dT} = \frac{-1.9859\times 529.7}{35.7294} 4.236 = \mathbf{-123.9\ Btu/lbmol}$$

12.162E

How low should the pressure be so that nitrous oxide (N_2O) gas at 501.6 R can be treated as an ideal gas with 5% accuracy or better?

From Table F.1: $T_c = 557.3$ R, $P_c = 1050$ psi

$$\Rightarrow \quad T_{r1} = \frac{501.6}{557.3} = 0.9$$

Look in Fig. D.1 following the curve $T_{r1} = 0.9$ to the point where Z = 0.95

$$P_{r1} = 0.125 \quad \text{so} \quad P < 0.125 \times 1050 \text{ psi} = \mathbf{131\ psi}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.163E

Nitrous oxide (N_2O) at 501.6 R is at a pressure so that it can be in a two-phase state. Find the generalized enthalpy departure for the two saturated states of liquid and vapor.

From Table F.1: $T_c = 557.3$ R, $P_c = 1050$ psi

$$\Rightarrow \quad T_{r1} = \frac{501.6}{557.3} = 0.9$$

From Fig. D.2:

Saturated liquid: $(h^* - h_f)/RT_c = 4.08$;

Saturated vapor: $(h^* - h_g)/RT_c = 0.875$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.164E

Find the heat of evaporation, h_{fg}, for R-134a at 30 F from the generalized charts and compare to the value in Table F.10.

From Table F.1: $T_c = 673.6$ R, $P_c = 589$ psia => $T_{r1} = \dfrac{489.7}{673.6} = 0.727$

$R = 1.98589/102.03 = 0.01946$ Btu/lbm-R

From Fig. D.2:

Saturated liquid: $(h^* - h_f)/RT_c = 4.7$;

Saturated vapor: $(h^* - h_g)/RT_c = 0.3$

$h_{fg} = h_g - h_f = RT_c\,[-0.3 - (-4.7)] = 4.4\ RT_c$

$= 4.4 \times 0.01946 \times 673.6 =$ **57.67 Btu/lbm**

Table F. 10: $h_{fg} =$ **85.63 Btu/lbm**

The approximation is not very good and can be improved by using the accentric factor.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.165E

A 7-ft^3 rigid tank contains propane at 1300 lbf/in.^{2}, 540 F. The propane is then allowed to cool to 120 F as heat is transferred with the surroundings. Determine the quality at the final state and the mass of liquid in the tank, using the generalized compressibility charts.

Propane C_3H_8:

$V = 7.0$ ft^3, $P_1 = 1300$ lbf/in.^{2}, $T_1 = 540$ F $= 1000$ R

cool to $T_2 = 120$ F $= 580$ R

From Table F.1 : $T_C = 665.6$ R, $P_C = 616$ lbf/in.^{2}

$$P_{r1} = \frac{1300}{616} = 2.110, \quad T_{r1} = \frac{1000}{665.6} = 1.502$$

From D.1: $Z_1 = 0.83$

$$v_2 = v_1 = \frac{Z_1 RT_1}{P_1} = \frac{0.83 \times 35.04 \times 1000}{1300 \times 144} = 0.1554 \text{ ft}^3/\text{lbm}$$

From D.1 at $T_{r2} = 0.871$, saturated => $P_{G2} = 0.43 \times 616 = 265$ lbf/in.^{2}

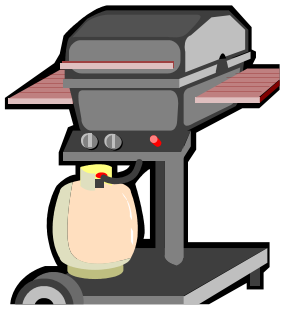
$$v_{G2} = \frac{0.715 \times 35.04 \times 580}{265 \times 144} = 0.3808 \text{ ft}^3/\text{lbm}$$

$$v_{F2} = \frac{0.075 \times 35.04 \times 580}{265 \times 144} = 0.0399 \text{ ft}^3/\text{lbm}$$

$0.1554 = 0.0399 + x_2(0.3781\text{-}0.0399)$ => $x_2 =$ **0.3388**

$$m_{LIQ\,2} = (1 - 0.3388)\frac{7.0}{0.1554} = \textbf{29.8 lbm}$$

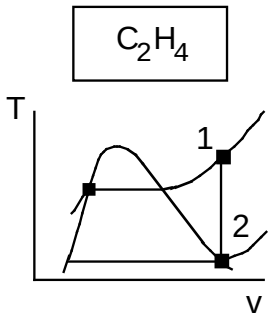
These tanks contain liquid propane.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.166E

A rigid tank contains 5 lbm of ethylene at 450 lbf/in.^{2}, 90 F. It is cooled until the ethylene reaches the saturated vapor curve. What is the final temperature?



C_2H_4 m = 5 lbm

P_1 = 450 lbf/in^2, T_1 = 90 F = 249.7 R

$$P_{r1} = \frac{450}{731} = 0.616, \quad T_{r1} = \frac{549.7}{508.3} = 1.082$$

Fig. D.1 $\Rightarrow$ $Z_1 = 0.82$

$$P_{r2} = P_{r1}\frac{Z_2 T_{r2}}{Z_1 T_{r1}} = 0.616\frac{Z_{G2} T_{r2}}{0.82 \times 1.082} = 0.6943\, Z_{G2} T_{r2}$$

Trial & error to match a saturated P_{r2}, T_{r2} and the Z_{G2} so Eq. is satisfied.

Guess a T_{r2} and find the rest and compare with computed P_{r2} from Eq.

T_{r2}	Z_{G2}	P_{r2}	$P_{r2\ CALC}$			
0.871	0.715	0.43	0.432	~ OK	=>	T_2 = **442.7 R**

12.167E

A piston/cylinder contains 10 lbm of butane gas at 900 R, 750 lbf/in.^{2}. The butane expands in a reversible polytropic process with polytropic exponent, $n = 1.05$, until the final pressure is 450 lbf/in.^{2}. Determine the final temperature and the work done during the process.

C_4H_{10} , m = 10 lbm , T_1 = 900 R , P_1 = 750 lbf/in.^{2}

Rev. polytropic process (n = 1.05), P_2 = 450 lbf/in.^{2}

$$T_{r1} = \frac{900}{765.4} = 1.176, \quad P_{r1} = \frac{750}{551} = 1.361 \quad \Rightarrow \quad \text{From Fig. D.1 :} \quad Z_1 = 0.67$$

$$V_1 = mZRT/P = \frac{10 \times 0.67 \times 26.58 \times 900}{750 \times 144} = 1.484 \text{ ft}^3$$

$$P_1V_1^n = P_2V_2^n \rightarrow V_2 = 1.484 \left(\frac{750}{450}\right)^{\frac{1}{1.05}} = 2.414 \text{ ft}^3$$

$$Z_2T_{r2} = \frac{P_2V_2}{mRT_C} = \frac{450 \times 144 \times 2.414}{10 \times 26.58 \times 765.4} = 0.7688$$

at P_{r2} = 450/551 = 0.817

Trial & error: $T_{r2} = 1.068$, $Z_2 = 0.72$ => T_2 = **817.4 R**

$$_1W_2 = \int_1^2 PdV = \frac{P_2V_2 - P_1V_1}{1-n} = \left(\frac{450 \times 2.414 - 750 \times 1.484}{1 - 1.05}\right) \times \frac{144}{778} = \textbf{98.8 Btu}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.168E

Calculate the heat transfer during the process described in Problem 12.167E.

From solution 12.167,

$V_1 = 1.473\ ft^3, \quad V_2 = 2.396\ ft^3, \quad {}_1W_2 = 98.8\ Btu$

$T_{r1} = 1.176, \quad P_{r1} = 1.361, \quad T_{r2} = 1.068, \quad P_{r2} = 0.817, \quad T_2 = 817.4\ R$

From D.1: $\left(\frac{h^*-h}{RT_C}\right)_1 = 1.36, \quad \left(\frac{h^*-h}{RT_C}\right)_2 = 0.95$

$h_2^* - h_1^* = 0.415\ (817.4 - 900) = -34.3\ Btu/lbm$

$h_2 - h_1 = -34.3 + \frac{26.58 \times 765.4}{778}(-0.95 + 1.36) = -23.6\ Btu/lbm$

$U_2 - U_1 = m(h_2 - h_1) - P_2V_2 + P_1V_1$

$= 10(-23.6) - \frac{450 \times 144 \times 2.414}{778} + \frac{750 \times 144 \times 1.484}{778} = -231.1\ Btu$

${}_1Q_2 = U_2 - U_1 + {}_1W_2 = \mathbf{-132.3\ Btu}$

12.169E

The new refrigerant R-152a is used in a refrigerator with an evaporator temperature of -10 F and a condensing temperature of 90 F. What are the high and low pressures in this cycle?

Since we do not have the printed tables for R-152a we will use generalized charts. The critical properties are: $T_c = 695.5$ R, $P_c = 656$ psi.

$T_{r1} = T/T_c = (459.67 - 10)/ 695.5 = 0.646$

Fig. D.1: $P_{G\,T1} = P_{r1\ sat}\, P_c = 0.06 \times 656 =$ **39.4 psi**

$T_{r2} = T/T_c = (459.67 + 90)/ 695.5 = 0.79$

Fig. D.1: $P_{G\,T2} = P_{r2\ sat}\, P_c = 0.25 \times 656 =$ **164 psi**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.170E

A cylinder contains ethylene, C_2H_4, at 222.6 lbf/in.^{2}, 8 F. It is now compressed in a reversible isobaric (constant *P*) process to saturated liquid. Find the specific work and heat transfer.

Ethylene C_2H_4 $P_1 = 222.6$ lbf/in.$^2 = P_2$, $T_1 = 8$ F = 467.7 R

State 2: saturated liquid, $x_2 = 0.0$

R = 55.07 ft lbf/lbm R = 0.070 78 Btu/lbm R

$$T_{r1} = \frac{467.7}{508.3} = 0.920 \quad P_{r1} = P_{r2} = \frac{222.6}{731} = 0.305$$

From D.1 and D.2: $Z_1 = 0.85$, $\left(\frac{h^*-h}{RT_C}\right)_1 = 0.40$

$$v_1 = \frac{Z_1 RT_1}{P_1} = \frac{0.85 \times 55.07 \times 467.7}{222.6 \times 144} = 0.683$$

$$(h_1^*-h_1) = 0.070\ 78 \times 508.3 \times 0.40 = 14.4$$

From D.1 and D.2: $T_2 = 0.822 \times 508.3 = 417.8$ R

$$Z_2 = 0.05, \quad \left(\frac{h^*-h}{RT_C}\right)_2 = 4.42$$

$$v_2 = \frac{Z_2 RT_2}{P_2} = \frac{0.05 \times 55.07 \times 417.8}{222.6 \times 144} = 0.035\ 89 \ \text{ft}^3/\text{lbm}$$

$$(h_2^*-h_2) = 0.070\ 78 \times 508.3 \times 4.42 = 159.0 \text{ Btu/lbm}$$

$$(h_2^*-h_1^*) = C_{P0}(T_2-T_1) = 0.411(417.8 - 467.7) = -20.5 \text{ Btu/lbm}$$

$$_1w_2 = \int_1^2 Pdv = P(v_2-v_1) = 222.6(0.035\ 89 - 0.683) \times \frac{144}{778} = \mathbf{-26.7\ Btu/lbm}$$

$$_1q_2 = (u_2 - u_1) + {}_1w_2 = (h_2-h_1) = -159.0 - 20.5 + 14.4 = \mathbf{-165.1\ Btu/lbm}$$

12.171E

Saturated vapor R-410A at 80 F is throttled to 30 lbf/in.^{2} in a steady flow process. Find the exit temperature, neglecting kinetic energy, using the generalized charts, Fig. D.2 and repeat using Table F.9.

R-410A throttling process, R = 1.98589/72.585 = 0.02736 Btu/lbm-R

T_1 = 80 F, x_1 = 1.00, P_2 = 30 lbf/in.^{2},

Energy Eq.: $h_2 - h_1 = (h_2 - h_2^*) + (h_2^* - h_1^*) + (h_1^* - h_1) = 0$

Generalized charts, $T_{r1} = \dfrac{539.7}{620.1} = 0.87$

From D.2: $(h_1^* - h_1) = 0.02736 \times 620.1 \times 0.75 = 12.72$ Btu/lbm

To get C_{P0}, use h values from Table F.9 at low pressure (5 psia).

$$C_{P0} \approx \frac{137.6 - 133.75}{80 - 60} = 0.1925 \text{ Btu/lbm R}$$

Substituting into energy Eq.: $(h_2 - h_2^*) + 0.1925\,(T_2 - 30) + 12.72 = 0$

at $P_{r2} = \dfrac{30}{711} = 0.042$

Assume T_2 = 10 F = 469.7 R => $T_{r2} = \dfrac{469.7}{620.1} = 0.757$

$(h_2^* - h_2) = 0.02736 \times 620.1 \times 0.07 = 1.19$

Substituting,

$-1.19 + 0.1925(10 - 80) + 12.72 = -1.945$

Guess T_2 = 20 F = 479.7 R => $T_{r2} = \dfrac{479.7}{620.1} = 0.774$

$(h_2^* - h_2) = 0.02736 \times 620.1 \times 0.07 = 1.19$

Substituting,

$-1.19 + 0.1925(20 - 80) + 12.72 = -0.02$ nearly OK

$\Rightarrow T_2$ **= 20 F** (maybe re-estimate C_{P0} at avg T)

R-410A tables, F.9: T_1 = 80 F, x_1 = 1.0 => h_1 = 122.14 Btu/lbm

$h_2 = h_1$ = 122.14 Btu/lbm, P_2 = 30 lbf/in.^{2} => T_2 = **8.15 F**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.172E

Find the heat of evaporation, h_{fg}, for isobutane (T_c = 735.8 R, P_c = 529.4 psia, M = 58.124) at 54.7 F from the generalized charts and compare to the values in the CATT3 computerized tables.

To read the charts we need the reduced temperature

$$T_{r1} = T/T_c = (54.7 + 459.7)/735.8 = 0.70$$

$$R = 1.98589 / 58.124 = 0.03417 \text{ Btu/lbm-R}$$

From Fig. D.2: $\quad (h^* - h)_g = 0.2\ RT_c \ ; \quad (h^* - h)_f = 4.85\ RT_c$

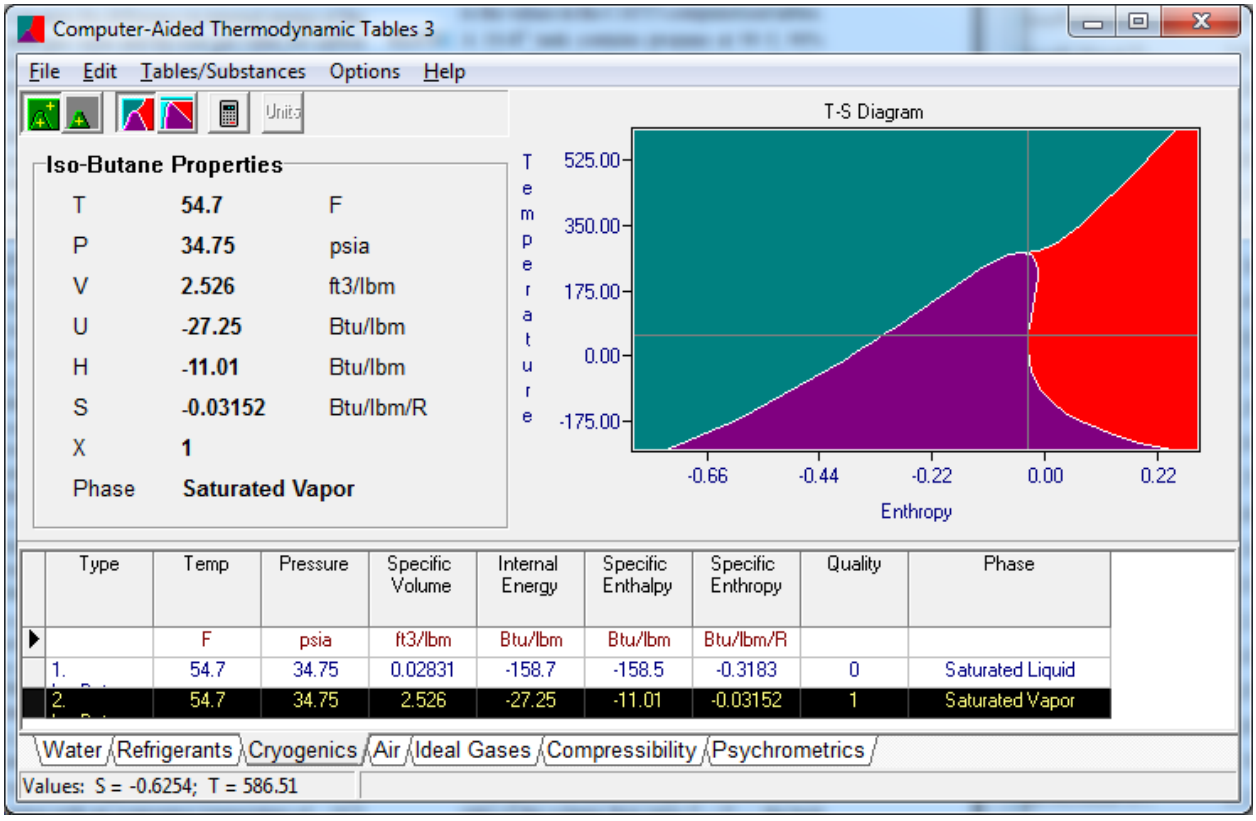
$$h_{fg} = h_g - h_f = -(h^* - h)_g - (h^* - h)_f = (-0.2 + 4.85)\ RT_c$$

$$= 4.65\ RT_c = 4.65 \times 0.03417 \text{ Btu/lbm-R} \times 735.8 \text{ R}$$

$$= \mathbf{116.9\ kJ/kg}$$

CATT3: $\quad h_{fg} = -11.01 - (-158.5) = \mathbf{147.5\ Btu/lbm}$

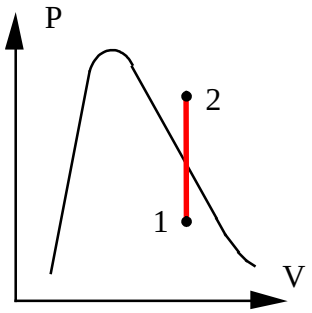
The generalized charts are not super accurate, some improvement can be done using the accentric factor.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.173E

A 10-ft^3 tank contains propane at 90 F, 90% quality. The tank is heated to 600 F. Calculate the heat transfer during the process.



$V = 10$ ft^3

$T_1 = 90$ F $= 549.7$ R, $x_1 = 0.90$

Heat to $T_2 = 600$ F $= 1059.7$ R

$M = 44.094$, $T_C = 665.6$ R

$P_C = 616$ lbf/in.^{2}

$R = 35.04$, $C_{P0} = 0.407$ Btu/lbm R

$T_{r1} = 0.826$ Figs. D.1 and D.2 $\rightarrow$ $Z_1 = 0.1 \times 0.053 + 0.9 \times 0.78 = 0.707$,

$$\frac{h_1^* - h_1}{RT_c} = 0.1 \times 4.4 + 0.9 \times 0.55 = 0.935$$

$$P_r^{SAT} = 0.31 \; ; \quad P_1^{SAT} = 0.31 \times 616 = 191 \text{ lbf/in.}^2$$

$$m = \frac{PV}{ZRT} = \frac{191 \times 144 \times 10}{0.707 \times 35.04 \times 549.7} = 20.2 \text{ lbm}$$

$$P_{r2} = \frac{20.2 \times Z_2 \times 35.04 \times 1059.7}{616 \times 144 \times 10} = \frac{Z_2}{1.183} \qquad \text{at } T_{r2} = 1.592$$

Trial & error:
$$\begin{cases} P_{r2} = 0.79 \text{ and } P_2 = 490 \text{ lbf/in.}^2 \\ Z_2 = 0.94 \text{ and } \dfrac{h_2^* - h_2}{RT_c} = 0.36 \end{cases}$$

$$(h_2^* - h_1^*) = 0.407(600-90) = 207.6 \text{ Btu/lbm}$$

$$(h_1^* - h_1) = 0.935 \times 35.04 \times 665.9/\ 778 = 28.0$$

$$(h_2^* - h_2) = 0.36 \times 35.04 \times 665.9/\ 778 = 10.8$$

From the energy equation

$$Q_{12} = m(h_2 - h_1) - (P_2 - P_1)V$$

$$= 20.2\ (-10.8 + 207.6 + 28.0) - (490 - 191) \times \frac{144 \times 10}{778}$$

$$= +4541 - 553 = \mathbf{3988\ Btu}$$

12.175E

A cylinder contains ethylene, C_2H_4, at 222.6 lbf/in.^{2}, 8 F. It is now compressed isothermally in a reversible process to 742 lbf/in.^{2}. Find the specific work and heat transfer.

Ethylene C_2H_4 , R = 55.07 ft lbf/lbm R = 0.070 78 Btu/lbm R

State 1: P_1 = 222.6 lbf/in.^{2}, $T_2 = T_1$ = 8 F = 467.7 R

State 2: P_2 = 742 lbf/in.^{2}

$$T_{r2} = T_{r1} = \frac{467.7}{508.3} = 0.920; \quad P_{r1} = \frac{222.6}{731} = 0.305$$

From D.1, D.2 and D.3: $Z_1 = 0.85$, $\left(\frac{h^* - h}{RT_C}\right)_1 = 0.40$

$$(h_1^* - h_1) = 0.070\ 78 \times 508.3 \times 0.40 = 14.4 \text{ Btu/lbm}$$

$$(s_1^* - s_1) = 0.070\ 78 \times 0.30 = 0.0212 \text{ Btu/lbm R}$$

$$P_{r2} = \frac{742}{731} = 1.015 \text{ (comp. liquid)}$$

From D.1, D.2 and D.3: $Z_2 = 0.17$

$$(h_2^* - h_2) = 0.070\ 78 \times 508.3 \times 4.0 = 143.9$$

$$(s_2^* - s_2) = 0.070\ 78 \times 3.6 = 0.2548$$

$$(h_2^* - h_1^*) = 0$$

$$(s_2^* - s_1^*) = 0 - 0.070\ 78 \ln \frac{742}{222.6} = -0.0852$$

$${}_1q_2 = T(s_2 - s_1) = 467.7(-0.2548 - 0.0852 + 0.0212) = \mathbf{-149.1\ Btu/lbm}$$

$$(h_2 - h_1) = -143.9 + 0 + 14.4 = -129.5$$

$$(u_2 - u_1) = (h_2 - h_1) - RT(Z_2 - Z_1)$$

$$= -129.5 - 0.070\ 78 \times 467.7\ (0.17 - 0.85) = -107.0$$

$${}_1w_2 = {}_1q_2 - (u_2 - u_1) = -149.1 + 107.0 = \mathbf{-42.1\ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.176E

A geothermal power plant on the Raft river uses isobutane as the working fluid. The fluid enters the reversible adiabatic turbine at 320 F, 805 lbf/in.^{2} and the condenser exit condition is saturated liquid at 91 F. Isobutane has the properties *Tc* = 734.65 R, *Pc* = 537 lbf/in.^{2}, *Cpo* = 0.3974 Btu/lbm R and ratio of specific heats *k* = 1.094 with a molecular weight as 58.124. Find the specific turbine work and the specific pump work.

R = 26.58 ft lbf/lbm R = 0.034 166 Btu/lbm R

Turbine inlet: $T_{r1} = 779.7 / 734.7 = 1.061$, $P_{r1} = 805 / 537 = 1.499$

Condenser exit: $T_3 = 91$ F , $x_3 = 0.0$; $T_{r3} = 550.7 / 734.7 = 0.75$

From D.1 : $P_{r3} = 0.165$, $Z_3 = 0.0275$

$P_2 = P_3 = 0.165 \times 537 = 88.6$ lbf/in.^{2}

From D.2 and D.3,

$(h_1^* - h_1) = 0.034\ 166 \times 734.7 \times 2.85 = 71.5$ Btu/lbm

$(s_1^* - s_1) = 0.034\ 166 \times 2.15 = 0.0735$ Btu/lbm R

$$(s_2^* - s_1^*) = 0.3974 \ln \frac{550.7}{779.7} - 0.034\ 166 \ln \frac{88.6}{805} = -0.0628 \text{ Btu/lbm R}$$

$(s_2^* - s_2) = (s_2^* - s_{F2}) - x_2 s_{FG2} = 0.034\ 166 \times 6.12 - x_2 \times 0.034\ 166(6.12 - 0.29)$

$= 0.2090 - x_2 \times 0.1992$

$(s_2 - s_1) = 0 = -0.2090 + x_2 \times 0.1992 - 0.0628 + 0.0735 \quad \Rightarrow \quad x_2 = 0.9955$

$(h_2^* - h_1^*) = C_{P0}(T_2 - T_1) = 0.3974(550.7 - 779.7) = -91.0$ Btu/lbm

From D.2,

$(h_2^* - h_2) = (h_2^* - h_{F2}) - x_2 h_{FG2} = 0.034\ 166 \times 734.7[4.69 - 0.9955(4.69 - 0.32)]$

$= 117.7 - 0.9955 \times 109.7 = 8.5$ Btu/lbm

Turbine: $w_T = (h_1 - h_2) = -71.5 + 91.0 + 8.5 =$ **28.0 Btu/lbm**

Pump $$v_{F3} = \frac{Z_{F3} R T_3}{P_3} = \frac{0.0275 \times 26.58 \times 550.7}{88.6 \times 144} = 0.031\ 55 \text{ ft}^3\text{/lbm}$$

$$w_P = -\int_3^4 v dP \approx v_{F3}(P_4 - P_3) = -0.031\ 55(805 - 88.6) \times \frac{144}{778} =$$ **-4.2 Btu/lbm**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.177E

A line with a steady supply of octane, C_8H_{18}, is at 750 F, 440 lbf/in.^{2}. What is your best estimate for the availability in an steady flow setup where changes in potential and kinetic energies may be neglected?

Availability of Octane at $T_i = 750$ F, $P_i = 440$ lbf/in.^{2}

R = 13.53 ft lbf/lbm-R = 0.017 39 Btu/lbm-R

$$P_{ri} = \frac{440}{361} = 1.219, \quad T_{ri} = \frac{1209.7}{1023.8} = 1.182$$

From D.2 and D.3:

$$(h_1^* - h_1) = 0.017\ 39 \times 1023.8 \times 1.15 = 20.5 \text{ Btu/lbm}$$

$$(s_1^* - s_1) = 0.017\ 39 \times 0.71 = 0.0123 \text{ Btu/lbm R}$$

Exit state in equilibrium with the surroundings

Assume $T_0 = 77$ F, $P_0 = 14.7$ lbf/in.^{2}

$$T_{r0} = \frac{536.7}{1023.8} = 0.524\ , \ P_{r0} = \frac{14.7}{361} = 0.041$$

From D.2 and D.3:

$$(h_0^* - h_0) = RT_C \times 5.41 = 96.3 \quad \text{and} \quad (s_0^* - s_0) = R \times 10.38 = 0.1805$$

$$(h_i^* - h_0^*) = 0.409(1209.7 - 536.7) = 275.3 \text{ Btu/lbm}$$

$$(s_i^* - s_0^*) = 0.409 \ln \frac{1209.7}{536.7} - 0.017\ 39 \ln \frac{440}{14.7} = 0.2733 \text{ Btu/lbm R}$$

$$(h_i - h_0) = -20.5 + 275.3 + 96.3 = 351.1 \text{ Btu/lbm}$$

$$(s_i - s_0) = -0.0123 + 0.2733 + 0.1805 = 0.4415 \text{ Btu/lbm R}$$

$$\psi_i = w^{rev} = (h_i - h_0) - T_0(s_i - s_0) = 351.1 - 536.7\ (0.4415) = \mathbf{114.1\ Btu/lbm}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.178E

A distributor of bottled propane, C_3H_8, needs to bring propane from 630 R, 14.7 lbf/in.^{2} to saturated liquid at 520 R in a steady flow process. If this should be accomplished in a reversible setup given the surroundings at 540 R, find the ratio of the volume flow rates V_{in}/V_{out}, the heat transfer and the work involved in the process.

R = 35.04/778 = 0.045 04 Btu/lbm R

$$T_{ri} = \frac{630}{665.6} = 0.947 \quad P_{ri} = \frac{14.7}{616} = 0.024$$

From D.1, D.2 and D.3 : $Z_i = 0.99$

$(h_i^* - h_i) = 0.045\ 04 \times 665.6 \times 0.03 = 0.9$ Btu/lbm

$(s_i^* - s_i) = 0.045\ 04 \times 0.02 = 0.0009$ Btu/lbm R

$T_{re} = 520/665.6 = 0.781,$

From D.1, D.2 and D.3 :

$P_{re} = = 0.21$, $P_e = 0.21 \times 616 = 129$ lbf/in.^{2} , $Z_e = 0.035$

$(h_e^* - h_e) = 0.045\ 04 \times 665.6 \times 4.58 = 137.3$ Btu/lbm

$(s_e^* - s_e) = 0.045\ 04 \times 5.72 = 0.2576$ Btu/lbm R

$(h_e^* - h_i^*) = 0.407\ (520 - 630) = -44.8$ Btu/lbm

$$(s_e^* - s_i^*) = 0.407 \ln \frac{520}{630} - 0.045\ 04 \ln \frac{132}{14.7} = -0.1770 \text{ Btu/lbm R}$$

$(h_e - h_i) = -137.3 - 44.8 + 0.9 = -181.2$ Btu/lbm

$(s_e - s_i) = -0.2576 - 0.1759 + 0.0009 = -0.4326$ Btu/lbm R

$$\frac{\dot{V}_{in}}{\dot{V}_{out}} = \frac{Z_i T_i / P_i}{Z_e T_e / P_e} = \frac{0.99}{0.035} \times \frac{630}{520} \times \frac{129}{14.7} = \mathbf{300.7}$$

$w^{rev} = (h_i - h_e) - T_0(s_i - s_e) = 181.2 - 540(0.4326) =$ **-52.4 Btu/lbm**

$q^{rev} = (h_e - h_i) + w^{rev} = -181.2 - 52.4 =$ **-233.6 Btu/lbm**

12.179E

A 4 lbm mixture of 50% argon and 50% nitrogen by mole is in a tank at 300 psia, 320 R. How large is the volume using a model of (a) ideal gas and (b) Kays rule with generalized compressibility charts.

a) Ideal gas mixture

Eq.11.5: $M_{mix} = \sum y_i M_i = 0.5 \times 39.948 + 0.5 \times 28.013 = 33.981$

$R = 1545.36 / 33.981 = 45.477$ lbf-ft/lbm-R

$$V = \frac{mRT}{P} = \frac{4 \times 45.477 \times 320}{300 \times 144} \frac{\text{lbf-ft}}{\text{psi} \times \text{in}^2/\text{ft}^2} = \mathbf{1.347\ ft^3}$$

b) Kay's rule Eq.12.84

$P_{c\ mix} = 0.5 \times 706 + 0.5 \times 492 = 599$ psia

$T_{c\ mix} = 0.5 \times 271.4 + 0.5 \times 227.2 = 249.3$ R

Reduced properties: $P_r = \frac{300}{599} = 0.50, \quad T_r = \frac{320}{249.3} = 1.284$

Fig. D.1: $Z = 0.92$

$$V = Z \frac{m\bar{R}T}{M_{mix}P} = Z\ V_{ID\ gas} = 0.92 \times 1.347 = \mathbf{1.24\ ft^3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.180E

R-410A is a 1:1 mass ratio mixture of R-32 and R-125. Find the specific volume at 80 F, 200 psia using Kays rule and the generalized charts and compare to Table F.9

Kay's rule Eq.12.84

$P_{c\ mix} = 0.5 \times 838 + 0.5 \times 525 = 681.5$ psia

$T_{c\ mix} = 0.5 \times 632.3 + 0.5 \times 610.6 = 621.45$ R

Reduced properties: $P_r = \dfrac{200}{681.5} = 0.293, \quad T_r = \dfrac{539.67}{621.45} = 0.868$

Table F.1: R = 1545.36 / 72.585 = 21.29 lbf-ft/lbm-R

Fig. D.1: Z = 0.82

$$v = \frac{ZRT}{P} = \frac{0.82 \times 21.29 \times 539.67}{200 \times 144} \frac{\text{lbf-ft/lbm}}{\text{psi} \times \text{in}^2/\text{ft}^2} = \mathbf{0.327\ ft^3/lbm}$$

Table F.9: $v = \mathbf{0.3174\ ft^3/lbm}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.181E

The R-410A in Problem 12.180E flows through a heat exchanger and exits at 280 F, 200 psia. Find the specific heat transfer using Kay's rule and the generalized charts and compare this to solution found using Table F.9.

Kay's rule Eq.12.84

$P_{c\,mix} = 0.5 \times 838 + 0.5 \times 525 = 681.5$ psia

$T_{c\,mix} = 0.5 \times 632.3 + 0.5 \times 610.6 = 621.45$ R

Table F.1: $R = 1545.36 / 72.585 = 21.29$ lbf-ft/lbm-R $= 0.02736$ Btu/lbm-R

$C_{P\,mix} = \sum c_i C_{P\,i} = 0.5 \times 0.196 + 0.5 \times 0.189 = 0.1925$ Btu/lbm-R

Reduced properties 1: $P_{r1} = \dfrac{200}{681.5} = 0.293$, $T_{r1} = \dfrac{539.67}{621.45} = 0.868$

Fig. D.1: $(h_1^* - h_1) = 0.45 \times RT_c = 0.45 \times 0.02736 \times 621.45 = 7.65$ Btu/lbm

Reduced properties 2: $P_{r2} = \dfrac{200}{681.5} = 0.293$, $T_{r2} = \dfrac{739.67}{621.45} = 1.19$

Fig. D.1: $(h_2^* - h_2) = 0.25 \times RT_c = 0.25 \times 0.02736 \times 621.45 = 4.25$ Btu/lbm

The energy equation gives

$$_1q_2 = (h_2 - h_1) = (h_2 - h_2^*) + (h_2^* - h_1^*) + (h_1^* - h_1)$$

$$= -4.25 + 0.1925\,(280 - 80) + 7.65$$

$$= \mathbf{41.9\ Btu/lbm\ mix}$$

Table F.9.2: $q = h_2 - h_1 = 176.26 - 126.34 =$ **49.92 Btu/lbm**

The main difference is in the value of specific heat, about 0.25 Btu/lbm-R at the avg. T, whereas it is 0.1925 Btu/lbm-R at 77 F.

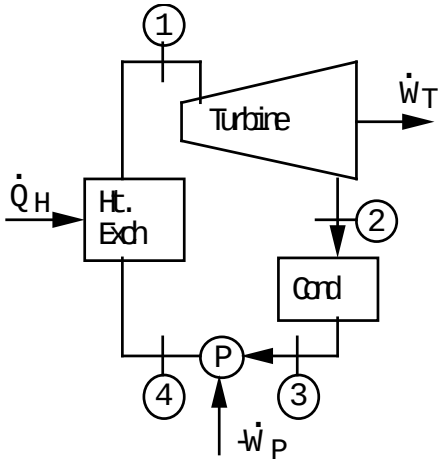
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Review Problem

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

12.182E

A new compound is used in an ideal Rankine cycle where saturated vapor at 400 F enters the turbine and saturated liquid at 70 F exits the condenser. The only properties known for this compound are a molecular mass of 80 lbm/lbmol, an ideal gas heat capacity of *Cpo* = 0.20 Btu/lbm-R and *Tc* = 900 R, *Pc* = 750 psia. Find the specific work input to the pump and the cycle thermal efficiency using the generalized charts.



T_1 = 400 F = 860 R

x_1 = 1.0

T_3 = 70 F = 530 R

x_3 = 0.0

Properties known:

M = 80, C_{PO} = 0.2 Btu/lbm R

T_C = 900 R, P_C = 750 lbf/in.^{2}

$$T_{r1} = \frac{860}{900} = 0.956, \quad T_{r3} = \frac{530}{900} = 0.589$$

From D.1: $P_{r1} = 0.76$, $P_1 = 0.76 \times 750 = 570$ lbf/in.$^2 = P_4$

$P_{r3} = 0.025$, $P_3 = 19$ lbf/in.$^2 = P_2$, $Z_{f3} = 0.0045$

$$v_{f3} = Z_{f3}RT_3/P_3 = \frac{0.0045 \times 1545 \times 530}{19 \times 144 \times 80} = 0.0168 \text{ ft}^3\text{/lbm}$$

$$w_P = -\int_3^4 v dP \approx v_{f3}(P_4 - P_3) = -0.0168\,(570 - 19) \times \frac{144}{778} = \mathbf{-1.71\ Btu/lbm}$$

$q_H + h_4 = h_1$, but $h_3 = h_4 + w_P$ => $q_H = (h_1 - h_3) + w_P$

From D.2,

$(h_1^* - h_1) = (1.9859/80) \times 900 \times 1.34 = 30.0$ Btu/lbm

$(h_3^* - h_3) = (1.9859/80) \times 900 \times 5.2 = 116.1$ Btu/lbm

$(h_1^* - h_3^*) = C_{P0}(T_1 - T_3) = 0.2(400\text{-}70) = 66.0$ Btu/lbm

$(h_1 - h_3) = -30.0 + 66.0 + 116.1 = 152.1$ Btu/lbm

$q_H = 152.1 + (-1.71) = 150.4$ Btu/lbm

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Turbine, $(s_2 - s_1) = 0 = -(s_2^* - s_2) + (s_2^* - s_1^*) + (s_1^* - s_1)$

From D.3,

$$(s_1^* - s_1) = (1.9859/80) \times 1.06 = 0.0263 \text{ Btu/lbm R}$$

$$(s_2^* - s_1^*) = 0.20 \ln \frac{530}{860} - 0.024\,82 \ln \frac{19}{570} = -0.0124 \text{ Btu/lbm R}$$

Substituting,

$$(s_2^* - s_2) = -0.0124 + 0.0263 = 0.0139 = (s_2^* - s_{f2}) - x_2 s_{fg2}$$

$$0.0139 = 0.024\,82 \times 8.77 - x_2 \times 0.024\,82\,(8.77 - 0.075)$$

$$\Rightarrow \quad x_2 = 0.9444$$

$$(h_2^* - h_2) = (h_2^* - h_{f2}) - x_2 h_{fg2}$$

From D.2,

$$h_{fg2} = 0.024\,82 \times 900\,(5.2 - 0.07) = 114.6 \text{ Btu/lbm}$$

$$(h_2^* - h_2) = 116.1 - 0.9444 \times 114.6 = 7.9 \text{ Btu/lbm}$$

$$w_T = (h_1 - h_2) = -30.0 + 66.0 + 7.9 = 43.9 \text{ Btu/lbm}$$

$$\eta_{TH} = \frac{w_{NET}}{q_H} = \frac{43.9 - 1.7}{150.4} = \mathbf{0.281}$$

In-Text Concept Questions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.a

How many kmol of air are needed to burn 1 kmol of carbon?

Combustion Eq.: $C + O_2 \Rightarrow 1\ CO_2$

One kmol of O_2 is required to form one kmol CO_2 . Since air is 21 % O_2 , this means 4.76 kmol of air.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.b

If I burn 1 kmol of hydrogen H_2 with 6 kmol of air what is the air-fuel ratio on a mole basis and what is the percent theoretical air?

Combustion Eq. stoichiometric:

$$H_2 + \nu_{O2}(O_2 + 3.76\ N_2) \Rightarrow 1\ H_2O + 3.76\ \nu_{O2}\ N_2$$

$$\nu_{O2} = 0.5\ ; \qquad (A/F)_S = \nu_{O2} \times (1 + 3.76) / 1 = 2.38$$

Six kmol of air is: $1.26\ O_2 + 4.74\ N_2$.

The A/F mole ratio is 6, so the percent theoretical air is

$$\%\text{Theoretical air} = \frac{(A/F)_{ac}}{(A/F)_S} \times 100 = \frac{6}{2.38} \times 100 = 252\ \%$$

Hydrogen flames are nearly colorless, but even small traces of other substances can give color.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.c

For the 110% theoretical air in Eq.13.8 what is the equivalence ratio? Is that mixture rich or lean?

110% Theoretical air means also $AF = 1.1\ AF_S$

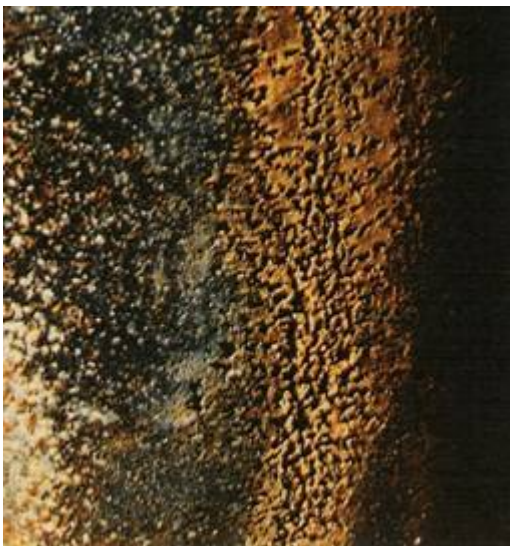
so from the definition in Eq.13.6

$$\Phi = \frac{AF_S}{AF} = \frac{1}{1.10} = 0.909$$ a lean mixture

13.d

In most cases combustion products are exhausted above the dew point. Why?

If any water in the products condenses, it will be acidic due to the other gases in the products. There are always minute amounts of unburned or partially burned fuel and intermediate species in the products that can combine with water and create a very corrosive mixture.



Corrosion on a metal surface.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.e

How is a fuel enthalpy of combustion connected to its enthalpy of formation?

The enthalpy of combustion of a fuel is the difference in enthalpy of the products and reactants for the combustion involving the fuel, these enthalpies include the various enthalpies of formation.

At reference condition: $$H^\circ_{RP} = H^\circ_P - H^\circ_R = H^\circ_P - \bar{h}^0_{f\ \text{fuel vap or liq}}$$

The value is negative so talk about the heating value as $HV = - H^\circ_{RP}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.f

What is the higher and lower heating value HHV, LHV of n-butane?

The heating value is the negative of the enthalpy of combustion. From Table 13.3, the HHV of gaseous n-butane at 25°C is

$$\text{HHV} = 49\ 500 \text{ kJ/kg},$$

and the corresponding LHV is

$$\text{LHV} = 45\ 714 \text{ kJ/kg}.$$

Notice the table is on a mass basis (per kg fuel).

A butane flame

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.g

What is the value of h_{fg} for n-octane?

This can be obtained from two places. From Table A.10 we get

$$h_{fg} = (\bar{h}^0_{f\ vap} - \bar{h}^0_{f\ liq}) / M = [(-208\ 600 - (-250\ 105)] / 114.232 = \mathbf{363\ kJ/kg}$$

The h_{fg} of a fuel listed in Table 13.3 is the difference between the first two columns in the table (or the third and fourth). For n-octane, this value is

$$h_{fg} = -47\ 893 - (-48\ 256) = \mathbf{363\ kJ/kg}$$

To see this remember

$$\overset{\circ}{H}_{RP} = \overset{\circ}{H}_P - \overset{\circ}{H}_R = \overset{\circ}{H}_P - \bar{h}^0_{f\ fuel\ vap\ or\ liq}$$

so when we take the difference between fuel as gas and fuel as liquid all other terms will cancel out leaving h_{fg} for the fuel when numbers are on mass basis.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.h

What happens to the adiabatic flame temperature if I burn rich or lean?

The higher the percent theoretical air used in combustion (the leaner), the larger the number of moles of products, especially nitrogen, which decreases the adiabatic flame temperature. Burning rich causes incomplete combustion, however, with a smaller release of energy.

Experimentally the highest temperature is reached for slightly rich.

Heavy molecules show up as yellow. Oxygen diffuses in from the air and the fuel evaporates from the wick. As air mixes in, the flame cools.

13.i

Is the irreversibility in a combustion process significant? Why is that?

A combustion process is highly irreversible with a large increase in entropy. It takes place at a rapid rate, due to large driving forces, and results in stable products of combustion that have little or no tendency to return to their former constituents and states.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.j

If the air-fuel ratio is larger than stoichiometric is it more or less reversible?

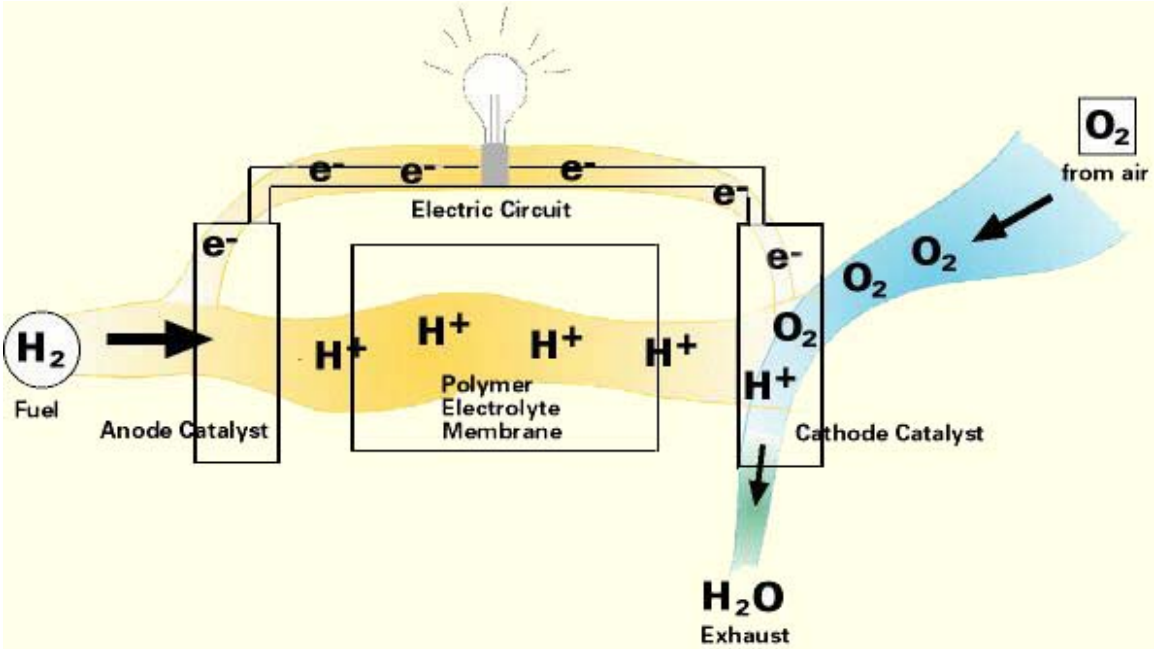
Less reversible, more irreversible. The excess oxidizer (air) is being heated up, Q over a finite temperature difference is an irreversible process. The same is true for A/F smaller than one where the excess fuel is heated up.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.k

What makes the fuel cell attractive from a power-generating point of view?

Fuel cells are attractive for power generation because their direct output is electrical energy. They also have a much higher power density as power per unit volume or power per unit mass and thus can be used in mobile applications.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Concept-Study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.1

Is mass conserved in combustion? Is the number of moles constant?

Yes mass is conserved as we do not consider the quantum physic effect of mass and energy conversion.

Moles are not conserved, what is conserved are the atoms so each atom in the reactants must be found in the products.

13.2

Does all combustion take place with air?

Most combustion takes place with air as the oxidizer, special cases do occur where a different oxidizer is used. To reach very high temperatures a gas welder uses a bottle of pure oxygen (and one with the fuel) instead of air and then the flame can cut through steel.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.3

Why would I sometimes need A/F on a mole basis? on a mass basis?

If you want to meter (measure) the fuel and air flows it can be done as a volume flowrate which is proportional to moles ($P\dot{V} = \dot{n}\bar{R}T$) in which case concentrations on a mole basis are needed.

The fuel and air flows can also be measured with a method that measures mass flow rate $\dot{m}$ or if you are filling up tanks to store the fuel and oxidizer as in a rocket in both cases the concentrations on a mass basis are needed.

13.4

Why is there no significant difference between the number of moles of reactants versus products in combustion of hydrocarbon fuels with air?

In most hydrocarbon fuels, there are approximately twice as many hydrogen atoms as carbon atoms, so the numbers of moles of CO_2 and H_2O in the products are roughly equal, the total of which is not too different from the O_2 required in the reactants. The number of excess O_2 is the same in reactants and products. The total number of moles is dominated by the N_2 in each, especially with excess air.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.5

Why are products measured on a dry basis?

Combustion products have traditionally been measured by passing the gas mixture through a series of solutions that selectively absorb the components one-by-one and measuring the resulting gas volume decreases. The water component is condensed out in these processes, leaving the others – that is, a dry basis. Other and newer instruments measure the concentrations by optical means and these are sensitive to moisture content, which can corrode the surfaces and destroy the sensors. If the water stays in the mixture it typically has to stay hot to prevent condensation at undesirable locations where that would alter the concentrations of the remaining gas mixture components.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.6

What is the dew point of hydrogen burned with stoichiometric pure oxygen? air?

For H_2 burned with pure oxygen

$$H_2 + 0.5\ O_2 \quad \Rightarrow \quad 1\ H_2O$$

with the only product as water, so the dew-point at 100 kPa pressure is **99.6°C**.

For H_2 burned with stoichiometric air

$$H_2 + 0.5\ (O_2 + 3.76\ N_2) \quad \Rightarrow \quad 1\ H_2O\ + 1.88\ N_2$$

the product mixture is water and nitrogen. The partial pressure of the water at a total pressure of 100 kPa is

$$P_v = P_{tot}\ y_v = 100 \times \frac{1}{1 + 1.88} = 34.7 \text{ kPa},$$

corresponding to a dew-point of **72.3°C** .

A hydrogen flame is nearly colorless. If other species are present they can give rise to some color of the flame.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.7

How does the dew point change as equivalence ratio goes from 0.9 to 1 to 1.1?

For a given amount of water in the products, the smaller the total number of moles of other gases is (as Φ increases), the higher the partial pressure of the water and therefore the dew-point temperature. As Φ becomes greater than 1.0, there will be incomplete combustion, and the resulting composition will be affected to have some unburned fuel and therefore relative less water. The relative maximum amount of water is then at a stoichiometric mixture Φ = 1 and this is also maximum dew point temperature.

13.8

Why does combustion contribute to global warming?

Any combustion of a hydrocarbon fuel produces carbon dioxide, which in the atmosphere is a contributing factor to global warming. Carbon dioxide absorbs radiation over a wide spectrum and thus heats the atmosphere. This is not just man-made, but nature has forest fires and volcanic action that liberate gases into the atmosphere.

Natural gas, mainly methane CH_4, has the highest hydrogen to carbon ratio of the hydrocarbons we find on earth (very little hydrogen can be found).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.9

What is the enthalpy of formation for oxygen as O_2? If O? For CO_2?

The enthalpy of formation of O_2 is zero, by choice of the reference base. Relative to this base, the value for the monatomic form O is

$$\bar{h}^{\circ}_{f\,O} = +249\,170 \text{ kJ/kmol (Table A.9)},$$

and the value for CO_2 is

$$\bar{h}^{\circ}_{f\,CO2} = -393\,522 \text{ kJ/kmol (Table A.9 or A.10)}.$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.10

If the nitrogen content of air could be lowered will the adiabatic flame temperature increase or decrease?

Since that would reduce the number of nitrogen molecules in the products it will increase the adiabatic flame temperature, more energy per molecule.

Energy Eq.: $\Delta H_P = HV + \Delta H_R$ = given

$$\Delta H_P = \nu_{CO_2} \Delta\bar{h}_{CO_2} + \nu_{H_2O} \Delta\bar{h}_{H_2O} + \nu_{N_2} \Delta\bar{h}_{N_2} \quad \text{at Tad}$$

so a lower ν_{N_2} means the $\Delta\bar{h}$'s must be larger.

13.11

Does the enthalpy of combustion depend on AF?

NO.

$H_{RP} = H_P - H_R$ depends on T, P in general.

Assuming ideal gas it does not depend on P.

It is assumed the number is scaled to 1 kmol or 1 kg of fuel burned.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.12

Why do some fuels not have entries for liquid fuel in Table 13.3?

Those fuels cannot exist as liquids at 25°C (above their critical temperature).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.13

Is a heating value a fixed number for a fuel?

Yes.

The heating value is the negative of the enthalpy of combustion and is only useful if it is a well defined number. It is fixed, but there are normally 4 values quoted as the **higher** (water liquid) and **lower** (water vapor) **heating value** for the fuel as a liquid or vapor if applicable. It should also be clear whether it is the enthalpies or the internal energies that are used, i.e. do you have a flow or a non flow situation. So these qualifiers must accompany the number for it to be unique.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.14

Is an adiabatic flame temperature a fixed number for a fuel?

Qualified **Yes.**

It is a single number if we assume reactants are supplied at the reference conditions in a stoichiometric ratio and we know the phase of the fuel (liquid or gas) and the type of oxidizer (air or pure oxygen). Also you need to know if the combustion takes place at constant pressure (the most common) or it may take place at constant volume (unusual). If anyone of these conditions is changed the adiabatic flame temperature is changed. This is less fixed than the heating value, more variables can change the adiabatic flame temperature, say, adding an inert gas will lower the flame temperature, but keep the heating value the same. Chemical equilibrium reactions and incomplete combustion makes the real flame temperature lower than the theoretical adiabatic flame temperature.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.15

Does it make a difference for the enthalpy of combustion whether I burn with pure oxygen or air? What about the adiabatic flame temperature?

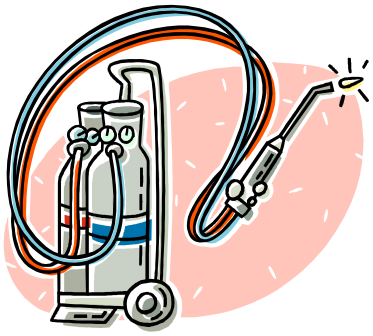
No difference in the enthalpy of combustion – the nitrogen in the air is the same in the reactants and products, and its enthalpy cancels out (nitrogen and oxygen formation enthalpy are both zero).

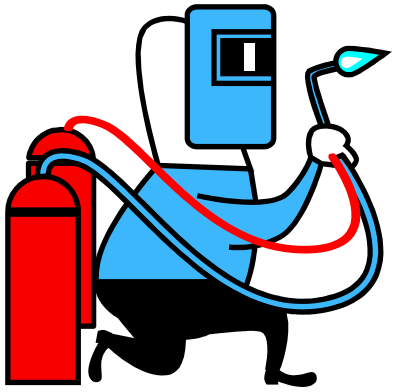
The adiabatic flame temperature is much lower for combustion with air, because a significant part of the energy release from the combustion goes into heating the nitrogen (as well as the other products) to the flame temperature.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.16

A welder uses a bottle with acetylene and a bottle with oxygen. Why does he use oxygen instead of air?





The oxygen in the air comes with nitrogen that is also being heated up to the flame temperature. The heating value is being shared among all the product components so when they increase (having the nitrogen also) the adiabatic flame temperature drops correspondingly.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.17

Some gas-welding is done using bottles of fuel, oxygen and argon. Why do you think argon is used?

Argon is used to shield the welding spot from the oxygen in the surrounding air. If oxygen is on the surface of the liquid metal it may form metal-oxides creating a weak location in the weld.

13.18

Is combustion a reversible process?

NO. It is a highly irreversible process.

13.19

Is combustion with more than 100% theoretical air more or less reversible?

It is **less** reversible. Any deviation from a stoichiometric mixture (lean or rich) will increase the irreversibility. You may also think of the adiabatic flame temperature which is highest for a stoichiometric mixture (like adding the heating value at that T). So with any other mixture the adiabatic flame temperature is lower so the heating value is added at a lower T (a more irreversible process).

13.20

In a picnic grill gaseous propane is fed to a burner together with stoichiometric air. Find the air-fuel ratio on a mass basis and the total amount of reactant mass for 1 kg propane burned.

The reaction equation for stoichiometric mixture is:

$$C_3H_8 + \nu_{O2} (O_2 + 3.76\ N_2) \rightarrow a\ H_2O + b\ CO_2 + c\ N_2$$

C balance: $3 = b$;

H balance: $8 = 2a \quad => \quad a = 4$

O balance: $2\ \nu_{O2} = a + 2b = 4 + 2 \times 3 \quad => \quad \nu_{O2} = 5$

N_2 balance: $3.76\ \nu_{O2} = c = 18.8$

The reaction is

$$C_3H_8 + 5 (O_2 + 3.76\ N_2) \rightarrow 4\ H_2O + 3\ CO_2 + 18.8\ N_2$$

$$AF_{mol} = \frac{5 + 18.8}{1} = 23.8$$

$$AF_{mass} = AF_{mol} \frac{M_{air}}{M_{fuel}} = 23.8 \times \frac{28.97}{44.097} = \mathbf{15.64}$$

Total mass of reactants = 1 + 15.64 = **16.64 kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.21

A mixture of fuels is E85, which is 85% ethanol and 15% gasoline (assume octane) by mass. Find the A/F ratio on a mass basis for stoichiometric combustion.

Since the fuel mixture is specified on a mass basis we need to find the mole fractions for the combustion equation. From Eq.13.4 we get

$$y_{ethanol} = (0.85/46.069) / [0.85/46.069 + 0.15/114.232] = 0.93356$$

$$y_{octane} = 1 - y_{ethanol} = 0.06644$$

The reaction equation is

$$0.93356\, C_2H_5OH + 0.06644\, C_8H_{18} + \nu_{O2}\,(O_2 + 3.76\, N_2)$$

$$\rightarrow \nu_{CO2}\, CO_2 + \nu_{H2O} H_2O + 3.76\, \nu_{O2}\, N_2$$

C balance: $2 \times 0.93356 + 8 \times 0.06644 = \nu_{CO2} = 2.39864$

H balance: $6 \times 0.93356 + 18 \times 0.06644 = 2\nu_{H2O} = 6.79728;\ \nu_{H2O} = 3.39864$

O balance: $0.93356 + 2\, \nu_{O2} = 2\, \nu_{CO2} + \nu_{H2O} = 8.19592 \Rightarrow \nu_{O2} = 3.63118$

The A/F ratio is

$$A/F = 4.76\, \nu_{O2} \times 28.97 / [0.93356 \times 46.069 + 0.06644 \times 114.232]$$

$$= \mathbf{9.896}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.22

Calculate the theoretical air-fuel ratio on a mass and mole basis for the combustion of ethanol, C_2H_5OH.

Reaction Eq.: $C_2H_5OH + \nu_{O2}(O_2 + 3.76N_2) \Rightarrow aCO_2 + bH_2O + cN_2$

Do the atom balance

Balance C: $2 = a$

Balance H: $6 = 2b \quad \Rightarrow \quad b = 3$

Balance O: $1 + 2\nu_{O2} = 2a + b = 4 + 3 = 7 \quad \Rightarrow \quad \nu_{O2} = 3$

$(A/F)_{mol} = \nu_{O2}(1 + 3.76)/1 = 3 \times 4.76 =$ **14.28**

$(A/F)_{mass} = (\nu_{O2}M_{O2} + \nu_{N2}\, M_{N2})/M_{Fuel}$

$= (3 \times 31.999 + 11.28 \times 28.013) / 46.069 =$ **8.943**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.23
Methane is burned with 200% theoretical air. Find the composition and the dew point of the products.

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow a\,H_2O + b\,CO_2 + c\,N_2$$

C balance: $1 = b$; H balance: $4 = 2a$

O balance: $2\,\nu_{O2} = a + 2b = 2 + 2 \times 1 \quad => \quad \nu_{O2} = 2$

N_2 balance: $3.76\,\nu_{O2} = c = 7.52$

200% theoretical air: $\nu_{O2} = 2 \times 2 = 4$ so now more O_2 and N_2

$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow a\,H_2O + b\,CO_2 + c\,N_2 + d\,O_2$$

N_2 balance: $3.76\,\nu_{O2} = c = 15.04$

Extra oxygen: $d = 4 - 1 - 1 = 2$

Products: $2\,H_2O + 1\,CO_2 + 15.04\,N_2 + 2\,O_2$

Water vapor mole fraction: $y_v = \dfrac{2}{1 + 2 + 2 + 15.04} = 0.0998$

Partial water vapor pressure: $P_v = y_v\,P_o = 0.0998 \times 101 = 9.98$ kPa

$$P_g(T_{dew}) = P_v = 9.98 \text{ kPa} \quad \Rightarrow \quad T_{dew} = \mathbf{45.8^oC}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.24

Natural gas B from Table 13.2 is burned with 20% excess air. Determine the composition of the products.

The reaction equation (stoichiometric and complete combustion) with the fuel composition is:

$$60.1\ CH_4 + 14.8\ C_2H_6 + 13.4\ C_3H_8 + 4.2\ C_4H_{10} + 7.5\ N_2$$
$$+ \nu_{O2}\ (O_2 + 3.76\ N_2) \rightarrow a\ H_2O + b\ CO_2 + c\ N_2$$

C balance: $60.1 + 2\times14.8 + 3\times13.4 + 4\times4.2 = b = 146.7$

H balance: $4\times60.1 + 6\times14.8 + 8\times13.4 + 10\times4.2 = 2a = 478.4 \Rightarrow a = 239.2$

O balance: $2\ \nu_{O2} = a + 2b = 239.2 + 2\times146.7 \Rightarrow \nu_{O2} = 266.3$

N_2 balance: $7.5 + 3.76\ \nu_{O2} = c = 1008.8$

20% excess air: $\nu_{O2} = 1.2\times266.3 = 319.56$ so now more O_2 and N_2

Extra oxygen: $d = 319.56 - 266.3 = 53.26$, $c = 7.5 + 3.76\times319.56 = 1209$

Products: $239.2\ H_2O + 146.7\ CO_2 + 1209\ N_2 + 53.26\ O_2$

To the expert the color of the flame can tell about the composition. It can tell about specific gases present if they have distinct color emission.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.25

A certain fuel oil has the composition $C_{10}H_{22}$. If this fuel is burned with 150% theoretical air, what is the composition of the products of combustion?

$$C_{10}H_{22} + (1/\phi)\,\nu_{O_2}\,(O_2 + 3.76\,N_2) \rightarrow a\,H_2O + b\,CO_2 + c\,N_2 + d\,O_2$$

Stoichiometric combustion: $\phi = 1$, $d = 0$,

C balance: $b = 10$

H balance: $a = 22/2 = 11$,

O balance: $2\,\nu_{O_2} = a + 2b = 11 + 20 = 31 \quad \Rightarrow \quad \nu_{O2} = 15.5$

Actual case: $1/\phi = 1.5 \quad \Rightarrow \quad \nu_{O2} = 1.5 \times 15.5 = 23.25$

H balance: $a = 11$, C balance: $b = 10$,

N balance: $c = 23.25 \times 3.76 = 87.42$

O_2 balance: $d = 23.25 - 10 - 11/2 = 7.75$ (excess oxygen)

The combustion process is

$$C_{10}H_{22} + 23.25\,(O_2 + 3.76\,N_2) \rightarrow 11\,H_2O + 10\,CO_2 + 87.42\,N_2 + 7.75\,O_2$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.26

A Pennsylvania coal contains 74.2% C, 5.1% H, 6.7% O, (dry basis, mass percent) plus ash and small percentages of N and S. This coal is fed into a gasifier along with oxygen and steam, as shown in Fig. P13.26. The exiting product gas composition is measured on a mole basis to: 39.9% CO, 30.8% H_2, 11.4% CO_2, 16.4% H_2O plus small percentages of CH_4, N_2, and H_2S. How many kilograms of coal are required to produce 100 kmol of product gas? How much oxygen and steam are required?

Convert the mass concentrations to number of kmol per 100 kg coal:

C : n = 74.2/12.01 = 6.178 $\qquad$ H_2: n = 5.1/2.016 = 2.530

O_2: n = 6.7/31.999 = 0.209

Now the combustion equation reads

$$x(6.178\,C + 2.53\,H_2 + 0.209\,O_2) + y\,H_2O + z\,O_2 \text{ in and}$$

$$39.9\,CO + 30.8\,H_2 + 11.4\,CO_2 + 16.4\,H_2O \text{ out}$$

in 100 kmol of mix out

Now we can do the atom balance to find (x, y, z)

C balance: $6.178\,x = 39.9 + 11.4 \rightarrow x = 8.304$

H_2 balance: $2.53 \times 8.304 + y = 30.8 + 16.4 \rightarrow y = 26.191$

O_2 balance: $0.209 \times 8.304 + \frac{26.191}{2} + z = \frac{39.9}{2} + 11.4 + \frac{16.4}{2} \rightarrow z = 24.719$

Therefore, for 100 kmol of mixture out

require: **830.4 kg** of coal

26.191 kmol of steam

24.719 kmol of oxygen

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.27

For complete stoichiometric combustion of gasoline, C_7H_{17}, determine the fuel molecular weight, the combustion products, and the mass of carbon dioxide produced per kg of fuel burned.

Stoichiometric combustion:

$$C_7H_{17} + \nu_{O_2}\,(O_2 + 3.76\,N_2) \;\Rightarrow\; a\,H_2O + b\,CO_2 + c\,N_2$$

C balance: $7 = b$

H balance: $17 = 2a, \quad \Rightarrow \quad a = 8.5$

O balance: $2\,\nu_{O_2} = a + 2b = 8.5 + 14 = 22.5 \quad \Rightarrow \quad \nu_{O_2} = 11.25$

N balance: $c = 3.76\;\nu_{O_2} = 3.76 \times 11.25 = 42.3$

$$M_{FUEL} = 7\,M_C + 17\,M_H = 7 \times 12.011 + 17 \times 1.008 = \mathbf{101.213}$$

$$\frac{m_{CO2}}{m_{FUEL}} = \frac{7\,M_{CO2}}{M_{FUEL}} = \frac{7 \times 44.01}{101.213} = \mathbf{3.044\ kg\ CO_2\ per\ kg\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.28

A sample of pine bark has the following ultimate analysis on a dry basis, percent by mass: 5.6% H, 53.4% C, 0.1% S, 0.1% N, 37.9% O and 2.9% ash. This bark will be used as a fuel by burning it with 100% theoretical air in a furnace. Determine the air–fuel ratio on a mass basis.

Converting the Bark Analysis from a mass basis:

Substance	S	H_2	C	O_2	N_2
c/M =	0.1/32	5.6/2	53.4/12	37.9/32	0.1/28
kmol / 100 kg coal	0.003	2.80	4.45	1.184	0.004
Product	SO_2	H_2O	CO_2		
oxygen required	0.003	1.40	4.45	--	--

Combustion requires: 0.003 + 1.40 + 4.45 = 5.853 kmol O_2 there is in the bark 1.184 kmol O_2 so the net from air is 4.669 kmol O_2

$$AF = (4.669 + 4.669 \times 3.76) \times \frac{28.97}{100} = \mathbf{6.44}\ \frac{\mathbf{kg\ air}}{\mathbf{kg\ bark}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.29

Liquid propane is burned with dry air. A volumetric analysis of the products of combustion yields the following volume percent composition on a dry basis: 8.6% CO_2, 0.6% CO, 7.2% O_2 and 83.6% N_2. Determine the percent of theoretical air used in this combustion process.

$$a\,C_3H_8 + b\,O_2 + c\,N_2 \rightarrow 8.6\,CO_2 + 0.6\,CO + d\,H_2O + 7.2\,O_2 + 83.6\,N_2$$

C balance: $3a = 8.6 + 0.6 = 9.2 \Rightarrow a = 3.067$

H_2 balance: $4a = d \Rightarrow d = 12.267$

N_2 balance: $c = 83.6$

O_2 balance: $b = 8.6 + \frac{0.6}{2} + \frac{12.267}{2} + 7.2 = 22.234$

$$\text{Air-Fuel ratio} = \frac{22.234 + 83.6}{3.067} = 34.51$$

Theoretical:

$$C_3H_8 + 5\,O_2 + 18.8\,N_2 \rightarrow 3\,CO_2 + 4\,H_2O + 18.8\,N_2$$

$$\Rightarrow \text{theo. A-F ratio} = \frac{5 + 18.8}{1} = 23.8$$

$$\%\ \text{theoretical air} = \frac{34.51}{23.8} \times 100\ \% = \mathbf{145\ \%}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.30

The coal gasifier in an integrated gasification combined cycle (IGCC) power plant produces a gas mixture with the following volumetric percent composition:

Product	CH_4	H_2	CO	CO_2	N_2	H_2O	H_2S	NH_3
% vol.	0.3	29.6	41.0	10.0	0.8	17.0	1.1	0.2

This gas is cooled to 40°C, 3 MPa, and the H_2S and NH_3 are removed in water scrubbers. Assuming that the resulting mixture, which is sent to the combustors, is saturated with water, determine the mixture composition and the theoretical air–fuel ratio in the combustors.

CH_4	H_2	CO	CO_2	N_2	n
0.3	29.6	41.0	10.0	0.8	81.7

$$y_{H2O} = \frac{n_v}{n_v + 81.7}, \quad \text{where} \quad n_v = \text{number of moles of water vapor}$$

Cool to 40°C $P_G = 7.384$, $P = 3000$ kPa

$$y_{H2O\ MAX} = \frac{7.384}{3000} = \frac{n_v}{n_v + 81.7} \quad \rightarrow \quad n_v = 0.2016$$

a) Mixture composition:

CH_4	H_2	CO	CO_2	N_2	H_2O(v)
0.3 kmol	29.6	41.0	10.0	0.8	0.2016

81.9016 kmol (from 100 kmol of the original gas mixture)

$$0.3\,CH_4 + 0.6\,O_2 \rightarrow 0.3\,CO_2 + 0.6\,H_2O$$

$$29.6\,H_2 + 14.8\,O_2 \rightarrow 29.6\,H_2O$$

$$41\,CO + 20.5\,O_2 \rightarrow 41\,CO_2$$

$\Rightarrow$ Number of moles of $O_2 = 0.6 + 14.8 + 20.5 = 35.9$

Number of moles of air = $35.9 + 3.76 \times 35.9$ (N_2)

$$A/F = \frac{28.97(35.9 + 3.76(35.9))}{0.3(16) + 29.6(2) + 41(28) + 10(44) + 0.8(28) + 0.2016(18)}$$

= **2.95 kg air/kg fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.31

In a combustion process with decane, $C_{10}H_{22}$, and air, the dry product mole fractions are 83.61% N_2, 4.91% O_2, 10.56% CO_2 and 0.92% CO. Find the equivalence ratio and the percent theoretical air of the reactants.

$$x\, C_{10}H_{22} + (1/\phi)\, \nu_{O_2} (O_2 + 3.76\, N_2) \rightarrow a\, H_2O + b\, CO_2 + c\, CO + d\, N_2 + e\, O_2$$

Stoichiometric combustion: $\phi = 1$, $c = 0$, $e = 0$,

C balance: $b = 10x$

H balance: $a = 22x/2 = 11x$,

O balance: $2\, \nu_{O_2} = a + 2b = 11x + 20x = 31x$

$\nu_{O_2} = 15.5x$, $\nu_{N_2} = 58.28x$ $\Rightarrow (A/F)_s = (\nu_{O_2} + \nu_{N_2})/x =$ **73.78**

Actual combustion: $d = 83.61$ $\rightarrow$

N balance: $(1/\phi)\, \nu_{O_2} \times 3.76 = 83.61 \rightarrow (1/\phi)\, \nu_{O_2} = 22.24$

C balance: $10x = 10.56 + 0.92 = 11.48 \Rightarrow x = 1.148$

$(A/F)_{ac} = (1/\phi)\, \nu_{O_2} \times 4.76/1.148 =$ **92.215**

$\phi = (F/A)_{ac} / (F/A)_s = (A/F)_s / (A/F)_{ac} = 73.78 / 92.215 =$ **0.80 or $\phi = 0.8$**

Percent theoretical air $= 100\, (1/\phi) =$ **125%**

13.32

The output gas mixture of a certain air–blown coal gasifier has the composition of producer gas as listed in Table 13.2. Consider the combustion of this gas with 120% theoretical air at 100 kPa pressure. Determine the dew point of the products and find how many kilograms of water will be condensed per kilogram of fuel if the products are cooled 10°C below the dew-point temperature.

$$\{3\,CH_4 + 14\,H_2 + 50.9\,N_2 + 0.6\,O_2 + 27\,CO + 4.5\,CO_2\}$$
$$+ 31.1\,O_2 + 116.9\,N_2 \rightarrow 34.5\,CO_2 + 20\,H_2O + 5.2\,O_2 + 167.8\,N_2$$

Products:

$$y_{H2O} = y_{H2O\ MAX} = P_G/100 = \frac{20}{34.5 + 20 + 5.2 + 167.8}$$

$$\Rightarrow P_G = 8.79\ \text{kPa} \quad \rightarrow \quad T_{DEW\ PT} = \mathbf{43.2°C}$$

At T = 33.2°C, P_G = 5.13 kPa

$$y_{H2O\ max} = \frac{5.13}{100} = \frac{n_{H2O}}{n_{H2O}+34.5+5.2+167.8} \quad \rightarrow \quad n_{H2O} = 11.22$$

$$m_{H2O\ LIQ} = \frac{8.78(18)}{3(16) +14(2) +50.9(28) +0.6(32) +27(28) +4.5(44)} = \mathbf{0.0639\ kg/kg\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.33

Methanol, CH_3OH, is burned with 200% theoretical air in an engine and the products are brought to 100 kPa, 30°C. How much water is condensed per kilogram of fuel?

$$CH_3OH + \nu_{O_2}\{O_2 + 3.76\ N_2\} \rightarrow CO_2 + 2\ H_2O + 3.76\ \nu_{O_2} N_2$$

Stoichiometric $\quad \nu_{O_2\ S} = 1.5 \quad \Rightarrow \quad \nu_{O_2\ AC} = 3$

Actual products: $CO_2 + 2\ H_2O + 1.5\ O_2 + 11.28\ N_2$

$P_{sat}(30°C) = 4.246$ kPa

$$\Rightarrow y_{H2O} = 0.04246 = \frac{\nu_{H2O}}{1 + \nu_{H2O} + 1.5 + 11.28}$$

$$\Rightarrow \nu_{H2O} = 0.611 \quad \Rightarrow \quad \Delta\nu_{H2O\ cond} = 2 - 0.611 = 1.389$$

$M_{Fu} = 32.042$ $\qquad \dfrac{\Delta M_{H2O}}{M_{Fu}} = \dfrac{1.389 \times 18}{32.042} = \mathbf{0.781}\ \dfrac{\mathbf{kg\ H_2O}}{\mathbf{kg\ fuel}}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.34

Butane is burned with dry air at 40°C, 100 kPa with AF = 22 on a mass basis. For complete combustion find the equivalence ratio, % theoretical air and the dew point of the products. How much water (kg/kg fuel) is condensed out, if any, when the products are cooled down to ambient temperature, 40°C?

Solution:

$$C_4H_{10} + \nu_{O_2}\{O_2 + 3.76\ N_2\} \rightarrow 4\ CO_2 + 5\ H_2O + 3.76\ \nu_{O_2} N_2$$

Stoichiometric $\nu_{O_2\ S} = 4 + 5/2 = 6.5$; $3.76\ \nu_{O_2} = 24.44$

$$(A/F)_S = 6.5(31.999 + 3.76 \times 28.013)/58.124 = 15.3574$$

Actual: $$\nu_{O_2 ac} = \frac{(A/F)_{ac}}{(A/F)_s}\nu_{O_2\ S} = \frac{22}{15.3574}6.5 = 9.31$$

$$\% \text{ Theoretical air} = \frac{22}{15.3574}100 = \mathbf{143.3\%}$$

Equivalence ratio $\Phi = 1/1.4325 = \mathbf{0.7}$

Actual products: $4\ CO_2 + 5\ H_2O + 2.81\ O_2 + 35.0\ N_2$

The water partial pressure becomes

$$P_v = y_v\ P_{tot} = \frac{5}{4 + 5 + 2.81 + 35.0}100 = 10.68\ \text{kPa}$$

$$T_{dew} = \mathbf{46.9^oC}$$

$$P_{g\ 40} = 7.348\ \text{kPa} \quad \Rightarrow \quad y_{v\ max} = \frac{7.384}{100} = \frac{\nu_{H2O}}{4 + \nu_{H2O} + 2.81 + 35.0}$$

Solve for $\nu_{H2O\ vap}$:

$\nu_{H2O\ vap} = 3.333$ still vapor,

$\nu_{H2O\ LIQ} = 5 - 3.333 = 1.667$ is liquid

$$\frac{m_{H2O\ LIQ}}{m_{Fuel}} = \frac{1.667 \times 18.015}{58.124} = \mathbf{0.517}$$

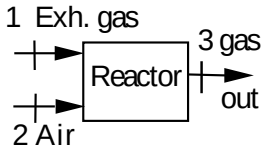
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.35

The hot exhaust gas from an internal combustion engine is analyzed and found to have the following percent composition on a volumetric basis at the engine exhaust manifold. 10% CO_2, 2% CO, 13% H_2O, 3% O_2 and 72% N_2. This gas is fed to an exhaust gas reactor and mixed with a certain amount of air to eliminate the carbon monoxide, as shown in Fig. P13.35. It has been determined that a mole fraction of 10% oxygen in the mixture at state 3 will ensure that no CO remains. What must the ratio of flows be entering the reactor?

Exhaust gas at state 1: CO_2 10 %, H_2O 13%,
CO 2%, O_2 3%, N_2 72%

Exhaust gas at state 3: CO = 0 %, O_2 = 10 %



Reaction equation for the carbon monoxide

$$\Rightarrow 0.02\,CO + x\,O_2 + 3.76x\,N_2 \rightarrow 0.02\,CO_2 + (x\text{-}0.01)\,O_2 + 3.76x\,N_2$$

At 3: $\nu_{CO_2} = 0.10 + 0.02 = 0.12$, $\nu_{H_2O} = 0.13$

$\nu_{O_2} = (x\text{-}0.01) + 0.03 = x + 0.02$ $\nu_{N_2} = 0.72 + 3.76x$

or

$$n_{TOT} = 0.12 + 0.13 + x + 0.02 + 0.72 + 3.76x = 0.99 + 4.76x$$

$$y_{O2} = 0.10 = \frac{x + 0.02}{0.99 + 4.76x} \quad \rightarrow \quad x = 0.151$$

or $$\frac{\text{air } 2}{\text{Exh. Gas } 1} = \frac{4.76x}{1} = \mathbf{0.718}\ \frac{\textbf{kmol air}}{\textbf{kmol Exh. gas}}$$

13.36

Acetylene gas C_2H_2 is burned with stoichiometric air in a torch. The reactants are supplied at the reference conditions Po, To. The products come out from the flame at 2500 K after some heat loss by radiation. Find the heat loss per kmol fuel.

The reaction equation is

$$C_2H_2 + 2.5\,(O_2 + 3.76\,N_2) \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$$

Energy Eq.: $H_P + Q_{out} = H_R = H_P^o + \Delta H_P + Q_{out} = H_R^o$

$$\Delta H_P = 2\,\Delta\bar{h}_{CO2} + \Delta\bar{h}_{H2O} + 9.4\,\Delta\bar{h}_{N2}$$
$$= 2 \times 121\,926.5 + 99\,130.5 + 9.4 \times 74\,301.5 = 1\,041\,418 \text{ kJ/kmol}$$
$$Q_{out} = H_R^o - H_P^o - \Delta H_P = \bar{h}^\circ_{f\,fuel} - \bar{h}^\circ_{f\,H_2O} - 2\,\bar{h}^\circ_{f\,CO_2} - \Delta H_P$$
$$Q_{out} = 226\,731 - (-241\,826) - 2(-393\,522) - 1\,041\,418$$
$$= \mathbf{214\,183 \text{ kJ/kmol fuel}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.37

Hydrogen is burned with stoichiometric air in a steady flow process where the reactants are supplied at 100 kPa, 298 K. The products are cooled to 800 K in a heat exchanger. Find the heat transfer per kmol hydrogen.

The combustion equation is

$$H_2 + 0.5 \times [\, O_2 + 3.76\, N_2\,] \rightarrow 1\, H_2O + 1.88\, N_2$$

The reactants are at 298 K

$H_R = 0 + 0 + 0 = 0$

The products are at 800 K so water is gaseous and from A.9

$H_P = 1[-241\,826 + 18\,002)] + 1.88\,(0 + 15\,046) = -195\,538$ kJ/kmol fuel

$Q_{CV} = H_P - H_R =$ **-195 538 kJ/kmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.38

Natural gas (methane) is burned with stoichiometric air, reactants supplied at reference Po, To in a steady flow burner. The products come out at 800 K, if the burner should deliver 10 kW what is the need flowrate of natural gas in kg/s?

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2} (O_2 + 3.76\ N_2) \rightarrow 2\ H_2O + 1\ CO_2 + c\ N_2$$

O balance: $2\ \nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2 \quad \Rightarrow \quad c = 2 \times 3.76 = 7.52$

The products are cooled to 800 K (so we do not consider condensation) and the energy equation is

Energy Eq.: $H_R + Q = H_P = H_P^\circ + \Delta H_P = H_R^\circ + Q$

$$Q = H_P^\circ + \Delta H_P - H_R^\circ = 2\ \bar{h}_{f\ H_2O}^\circ + \bar{h}_{f\ CO_2}^\circ + \Delta H_P - \bar{h}_{f\ fuel}^\circ$$

$$\Delta H_P = 2\ \Delta\bar{h}_{H2O} + \Delta\bar{h}_{CO2} + 7.52\ \Delta\bar{h}_{N2}$$
$$= 2 \times 18\ 002 + 22\ 806 + 7.52 \times 15\ 046 = 171\ 956$$
$$Q = 2(-241\ 826) - 393\ 522 + 171\ 956 - (-74\ 873)$$
$$= -630\ 345\ \text{kJ/kmol fuel}$$

$$\dot{Q} = \dot{n}\ Q_{out} = Q_{out}\ \dot{m}/M \qquad \text{so}$$

$$\dot{m} = \dot{Q}M/Q_{out} = 10\ \text{kW} \times 16.043\ (\text{kg/kmol}) / 630\ 345\ \text{kJ/kmol}$$
$$= \mathbf{0.0002545\ kg/s} = 0.916\ \text{kg/h}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.39

Butane gas and 200% theoretical air, both at 25°C, enter a steady flow combustor. The products of combustion exits at 1000 K. Calculate the heat transfer from the combustor per kmol of butane burned.

$$C_4H_{10} + (1/\phi)\,\nu_{O2}(O_2 + 3.76\,N_2) \rightarrow a\,CO_2 + b\,H_2O + c\,N_2 + d\,O_2$$

First we need to find the stoichiometric air ($\phi = 1$, $d = 0$)

C balance: $4 = a$, H balance: $10 = 2b \Rightarrow b = 5$

O balance: $2\nu_{O2} = 2a + b = 8 + 5 = 13 \Rightarrow \nu_{O2} = 6.5$

Now we can do the actual air: $(1/\phi) = 2 \Rightarrow \nu_{O2} = 2 \times 6.5 = 13$

N balance: $c = 3.76\,\nu_{O2} = 48.88$, O balance: $d = 13 - 6.5 = 6.5$

Energy Eq.: $q = H_R - H_P = H_R^o - H_P^o - \Delta H_P$

Table A.10: $H_R^o = -126\,200 + 0 + 0 = -126\,200$ kJ/kmol fuel

$H_P^o = 4\,(-393\,522) + 5(-241\,826) + 0 + 0 = -2\,783\,218$ kJ/kmol fuel

The rest of the values are from Table A.9 at 1000 K

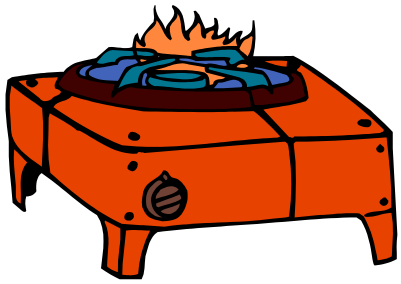
$\Delta\bar{h}_{CO2} = 33397$, $\Delta\bar{h}_{N2} = 21463$, $\Delta\bar{h}_{O2} = 22703$, $\Delta\bar{h}_{H2O} = 26000$ kJ/kmol

$\Delta H_P = 4 \times 33\,397 + 5 \times 26\,000 + 48.88 \times 21\,463 + 6.5 \times 22\,703$

$= 1\,460\,269$ kJ/kmol fuel

From the energy equation we get

$q = -126\,200 - (-2\,783\,218) - 1\,460\,269 =$ **1 196 749 kJ/kmol butane**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.40

One alternative to using petroleum or natural gas as fuels is ethanol (C_2H_5OH), which is commonly produced from grain by fermentation. Consider a combustion process in which liquid ethanol is burned with 110% theoretical air in a steady flow process. The reactants enter the combustion chamber at 25°C, and the products exit at 60°C, 100 kPa. Calculate the heat transfer per kilomole of ethanol.

$$C_2H_5OH + 1.1 \times 3\,(O_2 + 3.76\,N_2) \rightarrow 2CO_2 + 3H_2O + 0.3O_2 + 12.408N_2$$

Fuel: $\bar{h}_f^0$ = -277 380 kJ/kmol for liquid from Table A.10,

Products at 60°C, 100 kPa, check for condensation of water

$$y_{H2O\ MIX} = \frac{19.94}{100} = \frac{n_{V\ MAX}}{n_{V\ MAX} + 2 + 0.3 + 12.408}$$

$$\Rightarrow \quad n_{V\ MAX} = 3.66 > 3 \quad \Rightarrow \text{ No liquid}$$

$H_R = 1(-277\,380) + 0 + 0 = -277\,380$ kJ/kmol fuel

$H_P = 2(-393\,522 + 1373) + 3(-241\,826 + 1185)$

$+ 0.3(0 + 1039.5) + 12.408(0 + 1021) = -1\,493\,241$ kJ/kmol fuel

$Q_{CV} = H_P - H_R =$ **-1 215 860 kJ/kmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.41

Do the previous problem with the ethanol fuel delivered as a vapor.

One alternative to using petroleum or natural gas as fuels is ethanol (C_2H_5OH), which is commonly produced from grain by fermentation. Consider a combustion process in which liquid ethanol is burned with 120% theoretical air in a steady flow process. The reactants enter the combustion chamber at 25°C, and the products exit at 60°C, 100 kPa. Calculate the heat transfer per kilomole of ethanol.

$$C_2H_5OH + 1.1 \times 3\,(O_2 + 3.76\,N_2) \rightarrow 2CO_2 + 3H_2O + 0.3O_2 + 12.408N_2$$

Fuel: $\bar{h}_f^0$ = -235 000 kJ/kmol for IG from Table A.10

Products at 60°C, 100 kPa, check for condensation of water

$$y_{H2O\ MIX} = \frac{19.94}{100} = \frac{n_{V\ MAX}}{n_{V\ MAX} + 2 + 0.3 + 12.408}$$

$$\Rightarrow \quad n_{V\ MAX} = 3.66 > 3 \quad \Rightarrow \text{ No liquid}$$

The mixture can then hold 3.66 mol of vapor > 3 present $\Rightarrow$ No liquid.

$H_R = 1(-235\,000) + 0 + 0 = -235\,000$ kJ/kmol fuel

$H_P = 2(-393\,522 + 1373) + 3(-241\,826 + 1185)$

$+ 0.3(0 + 1039.5) + 12.408(0 + 1021) = -1\,493\,241$ kJ/kmol fuel

$Q_{CV} = H_P - H_R =$ **-1 258 241 kJ/kmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.42

As an alternative fuel consider liquid methanol burned with stoichiometric air both supplied at P_o, T_o in a constant pressure process exhausting the products at 900 K. What is the heat transfer per kmol of fuel.

$$CH_3OH + 1.5\,(O_2 + 3.76\,N_2) \rightarrow 1\,CO_2 + 2\,H_2O + 5.64\,N_2$$

Reactants at 25°C, products are at 900 K, 100 kPa.

CH_3OH: $\bar{h}_f^o$ = –239 220 kJ/kmol from table A.10 for the liquid state

$H_R = 1\,\bar{h}_{LIQ}$ = –239 220 kJ/kmol fuel

$H_P = 1(-393\,522 + 28\,030) + 2(-241\,826 + 21\,937) + 5.64(18\,223)$

= –702 492 kJ/kmol fuel

$Q = H_P - H_R$ = –702 492 – (–239 220) = **–463 272 kJ/kmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.43

The combustion of heptane C_7H_{16} takes place in a steady flow burner where fuel and air are added as gases at P_0, T_0. The mixture has 125% theoretical air and the products are going through a heat exchanger where they are cooled to 600 K.Find the heat transfer from the heat exchanger per kmol of heptane burned.

The reaction equation for stoichiometric ratio is:

$$C_7H_{16} + v_{O2}\,(O_2 + 3.76\,N_2) \Rightarrow 7CO_2 + 8\,H_2O + v_{O2} \times 3.76\,N_2$$

So the balance (C and H was done in equation) of oxygen gives

$$v_{O2} = 7 + 4 = 11, \qquad v_{O2\ ac} = 1.25 \times 11 = 13.75.$$

Now the actual reaction equation is:

$$C_7H_{16} + 13.75\,O_2 + 51.7\,N_2 \Rightarrow 7CO_2 + 8\,H_2O + 51.7\,N_2 + 2.75\,O_2$$

To find the heat transfer, take a control volume as combustion chamber and heat exchanger

$$H_R + Q = H_P \Rightarrow Q = H_P^o + \Delta H_P - H_R^o$$

Take the enthalpies from Tables A.9 for the products and A.10 for the fuel

$$Q = 7(-393\,522 + 12\,906) + 8\,(-241\,826 + 10\,499) + 51.7(8894)$$
$$+ 2.75(9245) - (-187\,900)$$

$$= \mathbf{-\ 3\,841\,784\ kJ/kmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.44

Pentene, C_5H_{10} is burned with stoichiometric pure oxygen in a steady flow process. After giving some heat out the products are at 700 K and used in a heat exchanger, where they are cooled to 35°C. Find the specific heat transfer in the heat exchanger.

$$C_5H_{10} + \nu_{O_2} O_2 \rightarrow 5\ CO_2 + 5\ H_2O \qquad \Rightarrow \qquad \nu_{O_2} = \mathbf{7.5}$$

Check for condensation amount

$$\text{Find x:} \quad y_{H_2O\ max} = \frac{P_g(35°)}{P_{tot}} = 0.0555 = \frac{x}{5 + x} \quad \Rightarrow \quad x = \mathbf{0.2938}$$

Out of the 5 H_2O only 0.2938 are still vapor at the 35°C exit temperature. The heat exchanger cools the products so the energy equation is

$$5\ \dot{n}_F\ \bar{h}_{CO_2} + 5\ \dot{n}_F\ \bar{h}_{H_2O} + \dot{Q} = 5\ \dot{n}_F\ \bar{h}_{CO_2}$$

$$+ (5 - x)\ \dot{n}_F\ \bar{h}_{liq\ H_2O} + (x)\ \dot{n}_F\ \bar{h}_{vap\ H_2O}$$

Find the enthalpy at 700 K all gas A.9 and at 35°C = 308.15 K part of water is a gas in table A.9 and use B.1.1 and A.10 for the liquid water.

$$\bar{h}_{liq\ H_2O} = \bar{h}^\circ_{f\ liq} + \Delta\bar{h}_{308} = -285\ 830 + 18.015(146.66 - 104.87) = -285\ 077$$

$$\bar{h}_{vap\ H_2O} = \bar{h}^\circ_{f\ vap} + \Delta\bar{h} = -241\ 826 + \Delta\bar{h}$$

$$\frac{\dot{Q}}{\dot{n}_F} = 5\ (\Delta\bar{h}_{308} - \Delta\bar{h}_{700})_{CO_2} + (5-x)[\ \bar{h}_{liq\ H_2O} - (\bar{h}^\circ_{f\ vap} + \Delta\bar{h}_{700})]_{H_2O}$$

$$+ x\ [\bar{h}^\circ_{f\ vap} + \Delta\bar{h}_{308} - (\bar{h}^\circ_{f\ vap} + \Delta\bar{h}_{700})]_{H_2O\ vapor}$$

$$= 5(389.6 - 17\ 754) + 4.706\ [-285\ 077 - (-241\ 826 + 14\ 190)]$$

$$+ 0.2938\ [(-241\ 826 + 338.1) - (-241\ 826 + 14\ 190)]$$

$$= \mathbf{-361\ 209\ kJ/kmol\ Fu}$$

13.45

Another alternative fuel to be seriously considered is hydrogen. It can be produced from water by various techniques that are under extensive study. Its biggest problem at the present time are cost, storage, and safety. Repeat Problem 13.40 using hydrogen gas as the fuel instead of ethanol.

$$H_2 + 1.1 \times 0.5\, O_2 + 1.1 \times 3.76 \times 0.5\, N_2 \rightarrow 1\, H_2O + 0.05\, O_2 + 2.068\, N_2$$

Products at 60°C, 100 kPa, check for condensation of water

$$y_{H2O\ MAX} = \frac{19.94}{100} = \frac{n_{V\ MAX}}{n_{V\ MAX} + 0.05 + 2.068}$$

Solving, $n_{V\ MAX} = 0.5275 < 1 \quad \Rightarrow \quad n_V = 0.5275, \quad n_{LIQ} = 0.4725$

$$H_R = 0 + 0 + 0 = 0$$

Notice the products are at 60°C so add for water liquid from steam tables

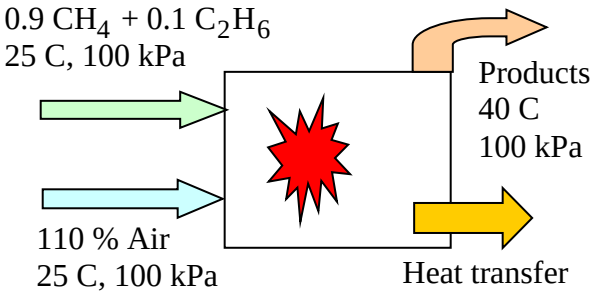
$$H_P = 0.4725\,[-285\,830 + 18.015\,(251.11 - 104.87)]$$
$$+ 0.5275\,(-241\,826 + 1185) + 0.05(0 + 1039.5) + 2.068(0 + 1021)$$
$$= -258\,585 \text{ kJ}$$

$$Q_{CV} = H_P - H_R = \mathbf{-258\,585\ kJ/kmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.46

In a new high-efficiency furnace, natural gas, assumed to be 90% methane and 10% ethane (by volume) and 110% theoretical air each enter at 25°C, 100 kPa, and the products (assumed to be 100% gaseous) exit the furnace at 40°C, 100 kPa. What is the heat transfer for this process? Compare this to an older furnace where the products exit at 250°C, 100 kPa.



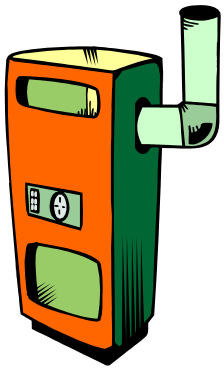
$$0.9\,CH_4 + 0.1\,C_2H_6 + 1.1 \times 2.15\,O_2 + 3.76 \times 2.365\,N_2$$
$$\rightarrow 1.1\,CO_2 + 2.1\,H_2O + 0.215\,O_2 + 8.892\,N_2$$

Fuel values from table A.10 and the rest from Table A.9

$H_R = 0.9(-74\,873) + 0.1(-84\,740) = -75\,860$ kJ/kmol fuel

$H_P = 1.1(-393\,522 + 586) + 2.1(-241\,826 + 507.5) + 0.215(445)$
$+ 8.892(437.6)$
$= -935\,012$ kJ/kmol fuel assuming all gas

$Q_{CV} = H_P - H_R =$ **-859 152 kJ/kmol fuel**



b) $T_P = 250\ ^oC$

$H_P = 1.1(-393\,522 + 9370) + 2.1(-241\,826 + 7750)$
$+ 0.215(6817) + 8.892(6602) = -853\,956$ kJ

$Q_{CV} = H_P - H_R =$ **-778 096 kJ/kmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.47

Repeat the previous problem, but take into account the actual phase behavior of the products exiting the furnace.

$$0.9\,CH_4 + 0.1\,C_2H_6 + 1.1 \times 2.15\,O_2 + 3.76 \times 2.365\,N_2$$
$$\rightarrow 1.1\,CO_2 + 2.1\,H_2O + 0.215\,O_2 + 8.892\,N_2$$

Same as 15.41, except check products for saturation at 40°C, 100 kPa

$$y_{v\,max} = \frac{7.384}{100} = \frac{n_{V\,MAX}}{n_{V\,MAX}+10.207} \quad \Rightarrow \quad \text{Solving, } n_{v\,max} = 0.814$$

$n_V = 0.814, \quad n_{liq} = 2.1 - 0.814 = 1.286$

Fuel values from table A.10 and the rest from Table A.9

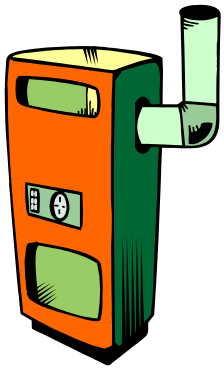
$H_R = 0.9(-74\,873) + 0.1(-84\,740) = -75\,860$ kJ/kmol fuel

For the liquid water add difference (40°C – 25°C) from steam tables

$H_{liq} = 1.286\left[-285\,830 + 18.015(167.6 - 104.9)\right] = -366\,125$ kJ/kmol fuel

$H_{GAS} = 1.1(-393\,522 + 586) + 0.814(-241\,826 + 507.5)$
$+ 0.215(445) + 8.892(437.6) = -624\,676$ kJ/kmol fuel

$Q_{CV} = H_P - H_R = (-366\,125 - 624\,676) + 75\,860$
$= \mathbf{-914\,941\ kJ/kmol\ fuel}$



b) $T_P = 250$ °C

$H_P = 1.1(-393\,522 + 9370) + 2.1(-241\,826 + 7750)$
$+ 0.215(6817) + 8.892(6602)$
$= -853\,956$ kJ/kmol

$Q_{CV} = H_P - H_R = \mathbf{-778\,096\ kJ/kmol\ fuel}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.48

Methane, CH_4, is burned in a steady adiabatic flow process with two different oxidizers: Case **A**: Pure oxygen, O_2 and case **B**: A mixture of $O_2 + x$ Ar. The reactants are supplied at T_0, P_0 and the products for both cases should be at 2100 K. Find the required equivalence ratio in case (A) and the amount of Argon, x, for a stoichiometric ratio in case (B).

a) Stoichiometric has $\nu = 2$, actual has:

$$CH_4 + \nu O_2 \rightarrow CO_2 + 2H_2O + (\nu - 2)O_2$$

Energy eq.: $H_R^\circ = H_P^\circ + \Delta H_{P\,2100}$

$$\Delta H_{P\,2100} = H_R^\circ - H_P^\circ = \bar{h}_{f\,fuel}^{o} + 0 - \bar{h}_{f\,CO_2}^{o} - 2\bar{h}_{f\,H_2O}^{o} - 0$$

$$RHS = -74\,873 - (-393\,522) - 2(-241\,826) = 802\,301 \text{ kJ/kmol}$$

$$\Delta\bar{h}_{CO_2} = 97\,500, \quad \Delta\bar{h}_{H_2O} = 77\,970, \quad \Delta\bar{h}_{O_2} = 62\,973 \quad \text{all in kJ/kmol}$$

$$\Delta H_{P\,2100} = \Delta\bar{h}_{CO_2} + 2\Delta\bar{h}_{H_2O} + (\nu - 2)\,\Delta\bar{h}_{O_2}$$

$$= 97\,500 + 2 \times 77\,970 + (\nu - 2) \times 62\,973$$

$$= 127\,494 + \nu\, 62\,973 = 802\,301 \text{ kJ/kmol fuel}$$

$$\Rightarrow \quad \mathbf{\nu = 10.72,} \quad \Phi = \frac{AF_S}{AF} = \frac{2}{10.72} = \mathbf{0.1866}$$

b) $$CH_4 + 2\,O_2 + 2x\,Ar \rightarrow CO_2 + 2H_2O + 2x\,Ar$$

$$\Delta\bar{h}_{Ar} = \bar{C}_{P\,Ar}\,\Delta T = C_{P\,Ar}\,M_{Ar}\,\Delta T \quad \text{from table A.5}$$

$$\Delta H_{P\,2100} = 97\,500 + 2 \times 77\,970$$

$$+ 2x \times 0.52 \times 39.948 \times (2100 - 298) = 253\,440 + x\,74\,866$$

Now the energy equation becomes

$$802\,301 = 253\,440 + x\,74\,866 \quad \Rightarrow \quad x = \mathbf{7.33}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.49

A rigid container has a 1:1 mole ratio of propane and butane gas together with a stoichiometric ratio of air at P_o, T_o. The charge burns and there is heat transfer to a final temperature of 1000 K. Find the final pressure and the heat transfer per kmol of fuel mixture.

$$C_3H_8 + C_4H_{10} + \nu_{O_2}(O_2 + 3.76\ N_2) \rightarrow 7\ CO_2 + 9\ H_2O + 3.76\ \nu_{O_2}\ N_2$$

The carbon and hydrogen balance has been used so oxygen gives

$$\nu_{O_2} = 7 + 9/2 = 11.5\ ; \quad \nu_{N_2} = 43.24$$

The energy equation is

$$U_P - U_R = Q - 0 = (H_P - H_R) - n_P\bar{R}T_P + n_R\bar{R}T_R$$

$$= H_P^o + \Delta H_P - H_R^o - n_P\bar{R}T_P + n_R\bar{R}T_R$$

$$n_R = 1 + 1 + 11.5 \times 4.76 = 56.74, \qquad n_P = 7 + 9 + 43.24 = 59.24$$

From Table A.9

$$\Delta H_P = 7\ (33\ 397) + 9\ (26\ 000) + 43.24\ (21\ 463) = 1\ 395\ 839\ kJ$$

From Table 13.3 (convert kJ/kg to kJ/kmol with M)

$$H_P^o - H_R^o = 44.094\ (-46\ 352) + 58.124\ (-45\ 714) = -\ 4\ 700\ 926\ kJ$$

Substitute into energy equation

$$Q = -\ 4\ 700\ 926 + 1\ 395\ 839 - 8.3145(59.24 \times 1000 - 56.74 \times 298.15)$$

$$= -\ 3\ 656\ 981\ kJ/2\ kmol\ fuel$$

$$= \mathbf{-\ 1\ 828\ 490\ kJ/kmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.50

A closed, insulated container is charged with a stoichiometric ratio of oxygen and hydrogen at 25°C and 150 kPa. After combustion, liquid water at 25°C is sprayed in such that the final temperature is 1200 K. What is the final pressure?

Combustion reaction: $H_2 + \frac{1}{2}(O_2) \rightarrow H_2O$

Products: $1\ H_2O + x_i H_2O$

Energy eq. per 1 kmol hydrogen (remember flow in):

$$U_2 - U_1 = x_i \bar{h}_i = x_i h^\circ_{f\ liq} = (1 + x_i)H_P - H_R - (1 + x_i)\bar{R}T_P + \tfrac{3}{2}\bar{R}T_R$$

Solve for x_i: $x_i\ [\ h^\circ_{f\ liq} - H_P + \bar{R}T_P\ ] = H_P - H_R - \bar{R}T_P + \frac{3}{2}\bar{R}T_R$

From Table A.9: $H_R = 0$, $H_P = -241\ 826 + 34\ 506 = -207\ 320$ kJ/kmol

From Table A.10: $h^\circ_{f\ liq} = -285\ 830$ kJ/kmol

Substitute into the energy equation

$$x_i\ (-285830 + 207320 + 8.3145 \times 1200) =$$

$$-207\ 320 - 8.3145(\ 1200 - \tfrac{3}{2} \times 298.15) = -213\ 579$$

$$x_i = 3.116$$

Volume is constant: $P_1V_1 = n_R\bar{R}T_1$, $P_2V_1 = n_p\bar{R}T_p$

$n_R = 1 + \frac{1}{2} = 1.5$; $n_p = (1 + x_i)$

$$P_2 = \frac{P_1(1 + x_i)T_P}{\frac{3}{2}(T_1)} = \frac{150 \times 4.116 \times 1200}{\frac{3}{2} \times 298.15} = \mathbf{1657\ kPa}$$

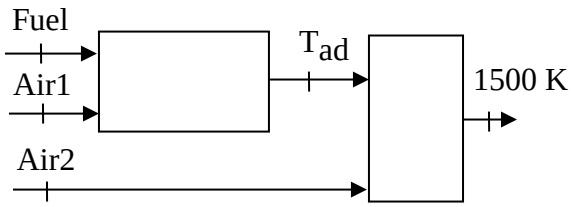
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.51

In a gas turbine natural gas (methane) and stoichiometric air flows into the combustion chamber at 1000 kPa, 500 K. Secondary air, see Fig.P13.51, also at 1000 kPa, 500 K is added right after the combustion to result in a product mixture temperature of 1500 K. Find the A/F ratio mass basis for the primary reactant flow and the ratio of the secondary air to the primary air (mass flow rates ratio).

$$CH_4 + \nu(O_2 + 3.76\ N_2) \rightarrow$$
$$CO_2 + 2H_2O + 3.76\ \nu\ N_2$$

O balance: $\nu = 2$, $\nu_{N2} = 7.52$



For the primary flow: $(A/F)_{mass} = \dfrac{2 \times 32 + 7.52 \times 28.013}{16.043} =$ **17.12**

Do a C.V. around the entire set-up, then the energy equation becomes

Energy Eq.: $H_{R1} + H_{R2} = H_{P\ 1500} = H_P^\circ + \Delta H_{P\ 1500}$

$$H_{R1} = H_R^\circ + \Delta H_{R1} = \bar{h}_{f\ fuel}^{o} + \Delta H_{Fuel} + \Delta H_{air1}$$

$\Delta H_{air1} = 2(\Delta H_{O2} + 3.76\ \Delta H_{N2}) = 2(6086 + 3.76 \times 5911) = 56\ 623$ kJ/kmol

$H_{R2} = 0 + \Delta H_{air2} = \nu_{O2\ add}\ (\Delta H_{O2} + 3.76\ \Delta H_{N2}) = \nu_{O2\ add}\ 28\ 311$ kJ/kmol

$\Delta H_{Fuel} \approx M\ C_P\ \Delta T = 16.043 \times 2.254\ (500 - 298) = 7304.5$ kJ/kmol

$$\bar{h}_{f\ fuel}^{o} - H_P^\circ = HV = 16.043 \times 50\ 010 = 802\ 310 \text{ kJ/kmol}$$

$$\Delta H_{P\ 1500} = \Delta\bar{h}_{CO_2} + 2\Delta\bar{h}_{H_2O} + 7.52\ \Delta\bar{h}_{N_2} + \nu_{O2\ add}\ (\Delta\bar{h}_{O_2} + 3.76\ \Delta\bar{h}_{N_2})$$
$$= 61\ 705 + 2 \times 48\ 149 + 7.52 \times 38\ 405 + \nu_{O2\ add}\ (40\ 600$$
$$+ 3.76 \times 38\ 405) = 446\ 809 + \nu_{O2\ add}\ 185\ 003 \text{ kJ/kmol}$$

Now substitute everything into energy equation

$$802\ 310 + 7304.5 + 56\ 623 + \nu_{O2\ add}\ 28\ 311 = 446\ 809 + \nu_{O2\ add}\ 185\ 003$$

$$\nu_{O2\ add} = 2.677$$

$$m_{air2}/m_{air1} = n_{air2}/n_{air1} = \nu_{O2\ add}/\ \nu = 2.677/2 = 1.34$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.52

A rigid vessel initially contains 2 kmol of carbon and 2 kmol of oxygen at 25°C, 200 kPa. Combustion occurs, and the resulting products consist of 1 kmol of carbon dioxide, 1 kmol of carbon monoxide, and excess oxygen at a temperature of 1000 K. Determine the final pressure in the vessel and the heat transfer from the vessel during the process.

$$2\,C + 2\,O_2 \rightarrow 1\,CO_2 + 1\,CO + \tfrac{1}{2}O_2$$

Process V = constant, C: solid, $n_{1(GAS)} = 2$, $n_{2(GAS)} = 2.5$

$$P_2 = P_1 \times \frac{n_2 T_2}{n_1 T_1} = 200 \times \frac{2.5 \times 1000}{2 \times 298.2} = \mathbf{838.4\ kPa}$$

$H_1 = 0$ and we neglect the Pv for carbon when doing the U_1.

$H_2 = 1(-393\,522 + 33\,397) + 1(-110\,527 + 21\,686)$

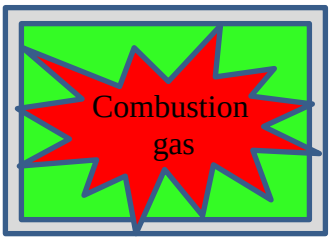
$+ (1/2)(0 + 22\,703) = -437\,615$ kJ

Now find heat transfer from energy equation

$${}_1Q_2 = (U_2 - U_1) = (H_2 - H_1) - n_2\bar{R}T_2 + n_1\bar{R}T_1$$

$= (-437\,615 - 0) - 8.3145(2.5 \times 1000 - 2 \times 298.2)$

$= \mathbf{-453\,442\ kJ}$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.53

Gaseous propane mixes with air, both supplied at 500 K, 0.1 MPa. The mixture goes into a combustion chamber and products of combustion exit at 1300 K, 0.1 MPa. The products analyzed on a dry basis are 11.42% CO_2, 0.79% CO, 2.68% O_2, and 85.11% N_2 on a volume basis. Find the equivalence ratio and the heat transfer per kmol of fuel.

$$C_3H_8 + \alpha\, O_2 + 3.76\, \alpha\, N_2 \rightarrow \beta\, CO_2 + \gamma\, H_2O + 3.76\, \alpha\, N_2$$

$$\beta = 3, \quad \gamma = 4, \quad \alpha = \beta + \gamma/2 = 5, \qquad (A/F)_S = 4.76\alpha = 23.8$$

The actual combustion reaction is

$$xC_3H_8 + \alpha\, O_2 + 3.76\, \alpha\, N_2 \rightarrow$$

$$11.42\, CO_2 + y\, H_2O + 85.11\, N_2 + 0.79\, CO + 2.68\, O_2$$

C balance: $3x = 11.42 + 0.79 \quad \Rightarrow \quad x = 4.07$

H balance: $8x = 2y \quad \Rightarrow \quad y = 4x = 16.28$

O balance: $2\alpha = 2 \times 11.42 + y + 0.79 + 2 \times 2.68 = 45.27 \quad \Rightarrow \quad \alpha = 22.635$

N balance: $3.76\, \alpha = 85.11 \quad \Rightarrow \quad \alpha = 22.6356$ checks close enough

Rescale the equation by dividing with x to give

$$C_3H_8 + 5.5614\, (O_2 + 3.76\, N_2) \rightarrow$$

$$2.806\, CO_2 + 4\, H_2O + 20.91\, N_2 + 0.194\, CO + 0.6584\, O_2$$

$$A/F = 5.5614\, (1 + 3.76) / 1 = 26.472$$

$\phi = (A/F)_S/(A/F) = 23.8 / 26.472 =$ **0.899,** %Theo. air $= 1/\phi =$ **111%**

$$q = h_P - h_R = h_P^o + \sum \nu_i \Delta h(1300\ K) - h_R$$

$$h_R = h_{f\ fuel}^o + \Delta h_{fuel} + 5.5614\, \Delta h_{O2} + 20.91\, \Delta h_{N2}$$

$$= -103\,900 + 1.679 \times 44.094\, (500 - 298) + 5.5614\, (6086)$$

$$+ 20.91\, (5911) = 68\,500\ kJ/kmol\ fuel$$

$$h_P = h_P^o + \sum \nu_i \Delta h(1300\ K)$$

$$= 2.806\, (-393\,522 + 50\,148) + 4(-241\,826 + 38\,941) + 20.91\, (0$$

$$+ 31\,503) + 0.194\, (-110\,527 + 31\,867) + 0.6584\, (0 + 33\,345)$$

$$= -1\,109\,625\ kJ/kmol\ fuel$$

$q = -1\,109\,625 - 68\,500 =$ **$-1\,178\,125$ kJ/kmol fuel**

Enthalpy of Combustion and Heating Value

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.54

Find the enthalpy of combustion and the heating value for pure carbon.

Reaction: $C + \nu_{O_2}[\, O_2 + 3.76\, N_2\,] \rightarrow CO_2 + \nu_{O_2} 3.76\, N_2$

oxygen balance: $\nu_{O_2} = 1$

$\overset{\circ}{H}_{RP} = H_P^o - H_R^o = \bar{h}_{f\,CO_2}^{\circ} - \bar{h}_{f\,C}^{\circ} = -393\,522 - 0$

$= -\mathbf{393\,522\ kJ/kmol} = \mathbf{-32\,791\ kJ/kg}$ (M = 12.011)

HV = 393 522 kJ/kmol = **32 791 kJ/kg**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.55

Phenol has an entry in Table 13.3, but it does not have a corresponding value of the enthalpy of formation in Table A.10. Can you calculate it?

$$C_6H_5OH + \nu_{O_2}[\ O_2 + 3.76\ N_2\ ] \rightarrow\ \ 3\ H_2O + 6\ CO_2 + 3.76\nu_{O_2}\ N_2$$

The C and H balance was introduced (6 C's and 6 H's). At the reference condition the oxygen and nitrogen have zero enthalpy of formation.

Energy Eq.: $H_P = H_R = H_P^o = H_R^o$ since ref. T is assumed.

$$H^\circ_{RP} = H_P - H_R = H_P^o - H_R^o = 3\ \bar{h}^\circ_{f\ H_2O} + 6\ \bar{h}^\circ_{f\ CO_2} - \bar{h}^\circ_{f\ fuel}$$

Table 13.3 is on a mass basis and let us chose liquid fuel, so we get the molecular weight from the composition

$$M = 6 \times 12.011 + 3 \times 2.016\ + 16 = 94.114$$

$$H^\circ_{RP} = 94.114\ (-31\ 117) = -2\ 928\ 545\ \text{kJ/kmol}$$

Solve the energy equation for fuel formation enthalpy

$$\bar{h}^\circ_{f\ fuel} = 3\ \bar{h}^\circ_{f\ H_2O} + 6\ \bar{h}^\circ_{f\ CO_2} - H^\circ_{RP}$$

$$= 3\ (-241\ 826) + 6(-393\ 522) - (-2\ 928\ 545)$$

$$= \mathbf{-158\ 065\ kJ/kmol}$$

For fuel as vapor we get

$$H^\circ_{RP} = 94.114\ (-31\ 774) = -2\ 990\ 378\ \text{kJ/kmol}$$

$$\bar{h}^\circ_{f\ fuel} = 3\ \bar{h}^\circ_{f\ H_2O} + 6\ \bar{h}^\circ_{f\ CO_2} - H^\circ_{RP}$$

$$= 3\ (-241\ 826) + 6(-393\ 522) - (-2\ 990\ 378)$$

$$= \mathbf{-96\ 232\ kJ/kmol}$$

Notice if I took liquid water in products to do H°_{RP} then I must use liquid value for $\bar{h}^\circ_{f\ H_2O} = -285\ 830$ kJ/kmol and the final result is the same.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.56

Acetylene gas, C_2H_2, is burned with stoichiometric air in a torch. The reactants are supplied at the reference conditions P_o, T_o. The products come out from the flame at 2800 K after a heat loss by radiation. Find the lower heating value for the fuel, as it is not listed in Table 13.3, and the heat loss per kmol of fuel.

The reaction equation is

$$C_2H_2 + 2.5\,(O_2 + 3.76\,N_2) \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$$

Definition of the heating value

$$\begin{aligned} LHV = -H^{\circ}_{RP} = H^{o}_{R} - H^{o}_{P} &= \bar{h}^{\circ}_{f\,fuel} - \bar{h}^{\circ}_{f\,H_2O} - 2\,\bar{h}^{\circ}_{f\,CO_2} \\ &= 226\,731 - (-241\,826) - 2(-393\,522) \\ &= 1\,255\,601\ \text{kJ/kmol} = \mathbf{48\,222\ kJ/kg} \end{aligned}$$

Energy Eq.: $H_P + Q_{out} = H_R = H^{o}_{P} + \Delta H_P + Q_{out} = H^{o}_{R}$

$$Q_{out} = H^{o}_{R} - H^{o}_{P} - \Delta H_P = LHV - \Delta H_P$$

$$\Delta H_P = 2 \times 140\,435 + 115\,463 + 9.4 \times 85\,323 = 1\,198\,369\ \text{kJ/kmol}$$

$$Q_{out} = 1\,255\,601 - 1\,198\,369 = \mathbf{57\,232\ kJ/kmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.57

Some type of wood can be characterized as $C_1H_{1.5}O_{0.7}$ with a lower heating value of 19 500 kJ/kg. Find its formation enthalpy.

$$C_1H_{1.5}O_{0.7} + \nu_{O_2}[\, O_2 + 3.76\, N_2\,] \rightarrow \quad CO_2 + 0.75\, H_2O + 3.76\nu_{O_2}\, N_2$$

O balance: $0.7 + 2\nu_{O_2} = 2 + 0.75 \quad \Rightarrow \quad \nu_{O_2} = 1.025,\ \nu_{N2} = 3.854$

$$M = 1 \times 12.0111 + 1.5 \times 1.008 + 0.7 \times 16 = 24.712$$

$$H^\circ_{RP} = H^o_P - H^o_R = -M \times HV = -24.712 \times 19\,500 = -481\,884 \text{ kJ/kmol}$$

$$= 0.75\, \bar{h}^\circ_{f\,H_2O} + 1\, \bar{h}^\circ_{f\,CO_2} - \bar{h}^\circ_{f\,fuel}$$

$$\bar{h}^\circ_{f\,fuel} = 0.75\, \bar{h}^\circ_{f\,H_2O} + 1\, \bar{h}^\circ_{f\,CO_2} + M \times HV$$

$$= 0.75\,(-241\,826) + (-393\,522) + 481\,884$$

$$= \mathbf{-93\,008 \text{ kJ/kmol}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.58

Do problem 13.40 using table 13.3 instead of Table A.10 for the solution.

One alternative to using petroleum or natural gas as fuels is ethanol (C_2H_5OH), which is commonly produced from grain by fermentation. Consider a combustion process in which liquid ethanol is burned with 120% theoretical air in a steady flow process. The reactants enter the combustion chamber at 25°C, and the products exit at 60°C, 100 kPa. Calculate the heat transfer per kilomole of ethanol.

$$C_2H_5OH + 1.1 \times 3\,(O_2 + 3.76\,N_2) \rightarrow 2\,CO_2 + 3\,H_2O + 0.3\,O_2 + 12.408\,N_2$$

Products at 60°C, 100 kPa, so check for condensation of water

$$y_{H2O\ MIX} = \frac{19.94}{100} = \frac{n_{V\ MAX}}{n_{V\ MAX} + 2 + 0.3 + 12.408}$$

$$\Rightarrow \quad n_{V\ MAX} = 3.66 > 3 \quad \Rightarrow \text{ No liquid}$$

Fuel: table 13.3 select (liquid fuel, water vapor) and convert to mole basis

$$\overset{\circ}{H}_{RP} = 46.069\,(-26\,811) = -1\,235\,156 \text{ kJ/kmol}$$

Since the reactants enter at the reference state the energy equation becomes

$$Q_{CV} = H_P - H_R = H_P^o + \Delta H_P - H_R^o = \overset{\circ}{H}_{RP} + \Delta H_P$$

$$\Delta H_P = 2\,\Delta\bar{h}_{CO_2} + 3\,\Delta\bar{h}_{H_2O} + 0.3\,\Delta\bar{h}_{O_2} + 12.408\,\Delta\bar{h}_{N_2}$$

$$= 2(1373) + 3(1185) + 0.3(1039.5) + 12.408(1021) = 19\,281 \text{ kJ/kmol}$$

$$Q_{CV} = -1\,235\,156 + 19\,281 = \mathbf{-1\,215\,874\ kJ/kmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.59

Agriculturally derived butanol, $C_4H_{10}O$, molecular mass 74.12, also called bio-butanol has a lower heating value LHV = 33 075 kJ/kg for liquid fuel. Find its formation enthalpy.

The reaction equation for stiochiometric ratio is:

$$C_4H_{10}O + \nu_{O2}(O_2 + 3.76\, N_2) \Rightarrow 4CO_2 + 5\, H_2O + \nu_{O2} \times 3.76\, N_2$$

where the carbon and hydrogen balance have been done. Now the oxygen

$$\text{O:} \quad 1 + 2\nu_{O2} = 4 \times 2 + 5 \quad \Rightarrow \quad \nu_{O2} = 6; \quad \nu_{N2} = 22.56$$

The lower heating value per kmol fuel is

$$\text{LHV} = -H^{\circ}_{RP} = H^{o}_{R} - H^{o}_{P} = \bar{h}^{\circ}_{f\ fuel} - 4\,\bar{h}^{\circ}_{f\ CO_2} - 5\,\bar{h}^{\circ}_{f\ H_2O}$$

so the fuel formation enthalpy becomes

$$\begin{aligned}\bar{h}^{\circ}_{f\ fuel} &= \text{LHV} + 4\,\bar{h}^{\circ}_{f\ CO_2} + 5\,\bar{h}^{\circ}_{f\ H_2O} \\ &= 74.12 \times 33\,075 + 4\,(-393\,522) + 5(-241\,826) \\ &= 2\,451\,519 - 1\,574\,088 - 1\,209\,130 \\ &= \mathbf{-331\,699\ kJ/kmol}\end{aligned}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.60

In a picnic grill, gaseous propane and stoichiometric air are mixed and fed to the burner both at ambient P_o and T_o. After combustion the products cool down and at some point exit at 500 K. How much heat transfer was given out for 1 kg of propane?

The reaction equation for stoichiometric mixture is:

$$C_3H_8 + \nu_{O2} (O_2 + 3.76\, N_2) \rightarrow a\, H_2O + b\, CO_2 + c\, N_2$$

C balance: $3 = b$;

H balance: $8 = 2a$ => $a = 4$

O balance: $2\,\nu_{O2} = a + 2b = 4 + 2 \times 3$

=> $\nu_{O2} = 5$

N_2 balance: $3.76\,\nu_{O2} = c = 18.8$

A/F = $5 \times 4.76 \times 28.97 / 44.094 = 15.637$

The reaction is

$$C_3H_8 + 5 (O_2 + 3.76\, N_2) \rightarrow 4\, H_2O + 3\, CO_2 + 18.8\, N_2$$

All the water is in the vapor phase (500 K products).

Energy Eq.: $H_R = Q_{out} + H_P$ => $H_R^o = Q_{out} + H_P^o + \Delta H_P$

A9: $\Delta H_P = 4 \times 6922 + 3 \times 8305 + 18.8 \times 5911 = 174\,682$ kJ/kmol fuel

$= (174\,682 / 44.094)$ kJ/kg $= 3961.6$ kJ/kg

Table 13.3: $-\overset{\circ}{H}_{RP} = HV = 46\,352$ kJ/kg

$$Q_{out} = H_R^o - H_P^o - \Delta H_P = -\overset{\circ}{H}_{RP} - \Delta H_P = HV - \Delta H_P$$

$= (46\,352 - 3961.6)$ kJ/kg fuel

= **42 390 kJ/kg fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.61

Propylbenzene, C_9H_{12}, is listed in Table 13.3, but not in table A.10. No molecular weight is listed in the book. Find the molecular weight, the enthalpy of formation for the liquid fuel and the enthalpy of evaporation.

$$C_9H_{12} + 12\ O_2 \rightarrow 9\ CO_2 + 6\ H_2O$$

$$\hat{M} = 9 \times 12.011 + 6 \times 2.016 = \mathbf{120.195}$$

$$\bar{h}^\circ_{RP} = = H^o_P - H^o_R = \sum_P \nu_i \bar{h}^\circ_{f_i} - \bar{h}^\circ_{f_{Fu}} \quad \Rightarrow \quad \bar{h}^\circ_{f_{Fu}} = \sum_P \nu_i \bar{h}^\circ_{f_i} - \bar{h}^\circ_{RP}$$

Formation enthalpies from Table A.10 and enthalpy of combustion from Table 13.3

$$\bar{h}^\circ_{f_{Fu}} = 9\bar{h}^\circ_{f_{CO_2}} + 6\bar{h}^\circ_{f_{H_2O\ g}} - \hat{M}(-41\ 219)_{liq\ Fu\ H_2O\ vap}$$

$$= 9(-393\ 522) + 6(-241\ 826) - 120.195(-41\ 219)$$

$$= \mathbf{-38\ 336\ kJ/kmol}$$

Take the enthalpy of combustion from Table 13.3 for fuel as a gas and as a vapor, the difference is the enthalpy of evaporation

$$h_{fg} = -(\bar{h}^\circ_{RP\ gas} - \bar{h}^\circ_{RP\ liq}) = 41\ 603 - 41\ 219 = \mathbf{384\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.62

Liquid pentane is burned with dry air and the products are measured on a dry basis as: 10.1% CO_2, 0.2% CO, 5.9% O_2 remainder N_2. Find the enthalpy of formation for the fuel and the actual equivalence ratio.

$$\nu_{Fu} C_5H_{12} + \nu_{O_2} O_2 + 3.76\, \nu_{O_2} N_2 \rightarrow$$

$$x\, H_2O + 10.1\, CO_2 + 0.2\, CO + 5.9\, O_2 + 83.8\, N_2$$

Balance of C: $5\, \nu_{Fu} = 10.1 + 0.2 \Rightarrow \nu_{Fu} = \mathbf{2.06}$

Balance of H: $12\, \nu_{Fu} = 2\, x \Rightarrow x = 6\, \nu_{Fu} = \mathbf{12.36}$

Balance of O: $2\, \nu_{O_2} = x + 20.2 + 0.2 + 2 \times 5.9 \Rightarrow \nu_{O_2} = \mathbf{22.28}$

Balance of N: $2 \times 3.76\, \nu_{O_2} = 83.8 \times 2 \Rightarrow \nu_{O_2} = \mathbf{22.287 \Rightarrow OK}$

ν_{O_2} for 1 kmol fuel = 10.816

$\phi = 1,\ C_5H_{12} + 8\, O_2 + 8 \times 3.76\, N_2 \rightarrow 6\, H_2O + 5\, CO_2 + 30.08\, N_2$

$$H^\circ_{RP} = H^\circ_P - H^\circ_R = 6\, \bar{h}^\circ_{f\, H_2O} + 5\, \bar{h}^\circ_{f\, CO_2} - \bar{h}^\circ_{f\, fuel}$$

Table 13.3: $H^\circ_{RP} = -44\,983 \times 72.151 = -3\,245\,568$ kJ/kmol fuel

$$\Rightarrow \quad \bar{h}^\circ_{f\, fuel} = 6\, \bar{h}^\circ_{f\, H_2O} + 5\, \bar{h}^\circ_{f\, CO_2} - H^\circ_{RP}$$

$$= 6\,(-241\,826) + 5\,(-393\,522) + 3\,245\,568$$

$$= \mathbf{-172\,998\ kJ/kmol}$$

$$\phi = AFs / AF = \nu_{O_2\, stoich} / \nu_{O_2\, AC} = 8/10.816 = \mathbf{0.74}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.63

Wet biomass waste from a food-processing plant is fed to a catalytic reactor, where in a steady flow process it is converted into a low-energy fuel gas suitable for firing the processing plant boilers. The fuel gas has a composition of 50% methane, 45% carbon dioxide, and 5% hydrogen on a volumetric basis. Determine the lower heating value of this fuel gas mixture per unit volume.

For 1 kmol fuel gas,

$$0.5\,CH_4 + 0.45\,CO_2 + 0.05\,H_2 + 1.025\,O_2 \rightarrow (0.5 + 0.45)\,CO_2 + 1.05\,H_2O$$

The lower heating value is with water vapor in the products. Since the $0.45\,CO_2$ cancels,

$$\bar{h}_{RP} = 0.5(-393\,522) + 1.05(-241\,826) - 0.5(-74\,873) - 0.05(0)$$

$$= -413\,242 \text{ kJ/kmol fuel gas}$$

With $\frac{n}{V} = P/\bar{R}T = \frac{100}{8.3145 \times 298.2} = 0.04033 \text{ kmol/m}^3$

$$LHV = +413\,242 \times 0.04033 = \mathbf{16\,666\ kJ/m^3}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.64

Determine the lower heating value of the gas generated from coal as described in Problem 13.30. Do not include the components removed by the water scrubbers.

The gas from problem 13.30 is saturated with water vapor. Lower heating value LHV has water as vapor.

$$LHV = -H^\circ_{RP} = H^\circ_P - H^\circ_R$$

Only CH_4, H_2 and CO contributes, find gas mixture after the scrubbers:

CH_4	H_2	CO	CO_2	N_2	n
0.3	29.6	41.0	10.0	0.8	81.7

Cool to 40°C $P_G = 7.384$, $P = 3000$ kPa

$$y_{H2O\ MAX} = \frac{7.384}{3000} = \frac{n_v}{n_v + 81.7} \quad \rightarrow \quad n_v = 0.2016$$

Mixture composition:

CH_4	H_2	CO	CO_2	N_2	H_2O(v)
0.3 kmol	29.6	41.0	10.0	0.8	0.2016

81.9016 kmol (from 100 kmol of the original gas mixture)

$$0.3\ CH_4 + 29.6\ H_2 + 41\ CO + 10\ CO_2 + 0.8\ N_2 + 0.2016\ H_2O$$

$$LHV = -[0.3\bar{H}^\circ_{RP_{CH4}} + 29.6\bar{H}^\circ_{RP_{H2}} + 41\bar{H}^\circ_{RP_{CO}}]/81.9$$

$$= -[0.3(-50\ 010 \times 16.043) + 29.6(-241\ 826) + 41(-393\ 522 + 110\ 527)]/81.9$$

$$= \mathbf{232\ 009}\ \frac{\mathbf{kJ}}{\mathbf{kmol\ gas}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.65

Do Problem 13.42 using Table 13.3 instead of Table A.10 for the solution.

As an alternative fuel consider liquid methanol burned with stoichiometric air both supplied at P_o, T_o in a constant pressure process exhausting the products at 900 K. What is the heat transfer per kmol of fuel.

$$CH_3OH + 1.5\,(O_2 + 3.76\,N_2) \rightarrow 1\,CO_2 + 2\,H_2O + 5.64\,N_2$$

Reactants at 25°C, products are at 900 K, 100 kPa.

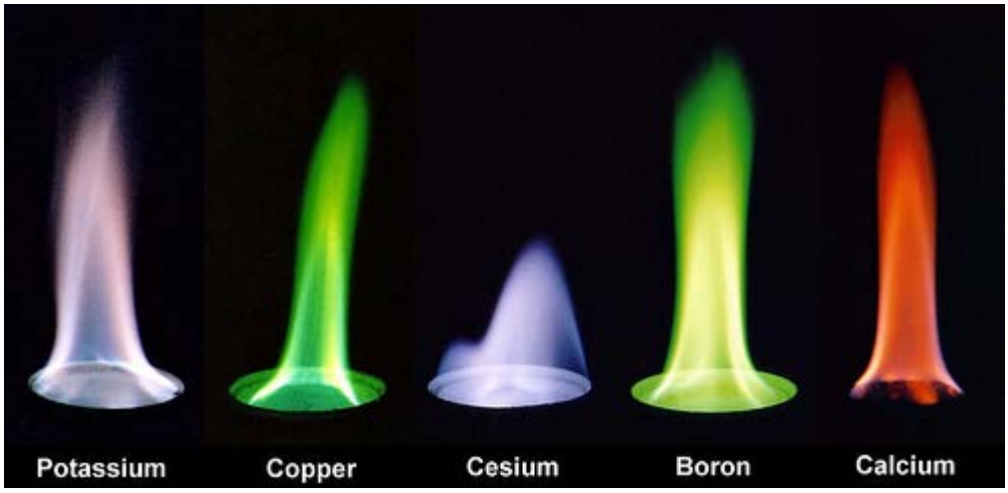
CH_3OH: From table 13.3 for liquid fuel, water vapor

$$\overset{\circ}{H}_{RP} = -19\,910 \text{ kJ/kg} = -19\,910 \times 32.042 = -637\,956 \text{ kJ/kmol fuel}$$

A9: $\Delta H_P = 1 \times 28\,030 + 2 \times 21\,937 + 5.64 \times 18\,223 = 174\,682$ kJ/kmol fuel

$$Q = H_{Po} + \Delta H_P - H_{Ro} = \overset{\circ}{H}_{RP} + \Delta H_P = -637\,956 + 174\,682$$

$$= \mathbf{-463\,274 \text{ kJ/kmol fuel}}$$



Various species added to the methanol changes the flame color

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.66

Do problem 13.43 using table 13.3 instead of Table A.10 for the solution.

The reaction equation for stiochiometric ratio is:

$$C_7H_{16} + \nu_{O2}\,(O_2 + 3.76\,N_2) \Rightarrow 7CO_2 + 8\,H_2O + \nu_{O2} \times 3.76\,N_2$$

So the balance (C and H was done in equation) of oxygen gives $\nu_{O2} = 7 + 4 = 11$, and actual one is $11 \times 1.25 = 13.75$. Now the actual reaction equation is:

$$C_7H_{16} + 13.75\,O_2 + 51.7\,N_2 \Rightarrow 7CO_2 + 8\,H_2O + 51.7\,N_2 + 2.75\,O_2$$

To find the heat transfer take a control volume as combustion chamber and heat exchanger

$$H_R + Q = H_P \quad \Rightarrow \quad Q = H_P^o + \Delta H_P - H_R^o = \overset{\circ}{H}_{RP} + \Delta H_P$$

Now we get the enthalpy of combustion from table 13.3, which is per kg, so scale it with the molecular weight for the fuel. Add all the ΔH_P from A.9

$$\Delta H_P = 7\,\Delta\bar{h}_{CO_2} + 8\,\Delta\bar{h}_{H_2O} + 51.7\,\Delta\bar{h}_{N_2} + 2.75\,\Delta\bar{h}_{O_2}$$

$$= 7(12\,906) + 8(10\,499) + 51.7(8894) + 2.75(9245) = 659\,578\ \frac{\text{kJ}}{\text{kmol}}$$

$$Q = M\,\overset{\circ}{H}_{RP} + \Delta H_P = 100.205(-44\,922) + 659\,578$$

$$= \mathbf{-\ 3\,841\,831\ kJ/kmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.67

E85 is a liquid mixture of 85% ethanol and 15% gasoline (assume octane) by mass. Find the lower heating value for this blend.

The heating value of the blend becomes

$$\begin{aligned} LHV &= 0.85\ LHV_{ethanol} + 0.15\ LHV_{octane} \\ &= 0.85\ (26\ 811) + 0.15\ (44\ 425) \quad kJ/kg \\ &= \mathbf{29\ 453\ kJ/kg} \end{aligned}$$

As this is lower than gasoline a larger amount of fuel is being used for the same energy release in the engine. If the mixture was given on a mole basis we would have used LHV on a mole basis instead (multiplying Table 13.3 entries by M).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.68

Assume the products of combustion in Problem 13.67 are sent out of the tailpipe and cool to ambient 20°C. Find the fraction of the product water that will condense.

Since the fuel mixture is specified on a mass basis we need to find the mole fractions for the combustion equation. From Eq.13.4 we get

$$y_{ethanol} = (0.85/46.069) / [0.85/46.069 + 0.15/114.232] = 0.93356$$

$$y_{octane} = 1 - y_{ethanol} = 0.06644$$

The reaction equation is

$$0.93356\, C_2H_5OH + 0.06644\, C_8H_{18} + \nu_{O2}\,(O_2 + 3.76\, N_2)$$

$$\rightarrow \nu_{CO2}\, CO_2 + \nu_{H2O} H_2O + 3.76\, \nu_{O2}\, N_2$$

C balance: $2 \times 0.93356 + 8 \times 0.06644 = \nu_{CO2} = 2.39864$

H_2 balance: $3 \times 0.93356 + 9 \times 0.06644 = \nu_{H2O} = 3.39864$

O balance: $0.93356 + 2\, \nu_{O2} = 2\, \nu_{CO2} + \nu_{H2O} = 8.19592 \quad => \nu_{O2} = 3.63118$

Now the products are:

$$2.39864\, CO_2 + 3.39864\, H_2O + 13.65324\, N_2$$

Check for condensation amount

Find x: $$y_{H_2O\ max} = \frac{P_g(20°)}{P_{tot}} = \frac{2.339}{101.325} = 0.023084 = \frac{x}{2.39864 + x + 13.65324}$$

$\Rightarrow$ x = 0.3793 mol of water can stay vapor.

Condensing water = 3.39864 – 0.3793 = 3.01934 or **89%**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.69

Gaseous propane and stoichiometric air are mixed and fed to a burner both at ambient P_o and T_o. After combustion the products cool down and eventually reach ambient T_o. How much heat transfer was given out for 1 kg of propane?

The reaction equation for stoichiometric mixture is:

$$C_3H_8 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow a\,H_2O + b\,CO_2 + c\,N_2$$

C balance: $3 = b$;

H balance: $8 = 2a \quad => \quad a = 4$

O balance: $2\,\nu_{O2} = a + 2b = 4 + 2 \times 3$

$$=> \quad \nu_{O2} = 5$$

N_2 balance: $3.76\,\nu_{O2} = c = 18.8$

A/F = $5 \times 4.76 \times 28.97 / 44.094 = 15.637$

The reaction is

$$C_3H_8 + 5\,(O_2 + 3.76\,N_2) \rightarrow 4\,H_2O + 3\,CO_2 + 18.8\,N_2$$

First we solve the problem assuming all the water is in the vapor phase and then we can solve with the proper split of water into liquid and vapor masses.

Energy Eq.: $H_R = Q_{out} + H_P \quad => \quad H_R^o = Q_{out} + H_P^o$

$$Q_{out} = H_R^o - H_P^o = -H_{RP}^\circ = HV = 46\,352 \text{ kJ/kg fuel}$$

At T_o we need to check for condensation of water partial P limited to P_g.

$$y_{v\,max} = \frac{P_g}{P} = \frac{3.169}{100} = \frac{n_{v\,max}}{n_{v\,max} + 3 + 18.8}$$

$$\Rightarrow \quad n_{v\,max} = 0.7135 \quad \text{and then} \quad n_{liq} = 4 - n_{v\,max} = 3.2865$$

So now we know the split of the 4 moles of water into vapor and liquid. The change in the heating value becomes ($HV_{liq\ water} = 50\,343$ kJ/kg fuel)

$$Q_{out} = HV = \frac{0.7135}{4}\,46\,352 + \frac{3.2865}{4}\,50\,343 = \mathbf{49\,631\ kJ/kg\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.70

In an experiment a 1:1 mole ratio propane and butane is burned in a steady flow with stoichiometric air. Both fuels and air are supplied as gases at 298 K and 100 kPa. The products are cooled to 1000 K as they give heat to some application. Find the lower heating value (per kg fuel mixture) and the total heat transfer for 1 kmol of fuel mixture used.

Combustion: $C_3H_8 + C_4H_{10} + 11.5(O_2 + 3.76\ N) \rightarrow 7\ CO_2 + 9\ H_2O + 43.24\ N_2$

$$\nu_{O2} = 7 + 9/2 = 11.5 \quad \Rightarrow \quad \nu_{N2} = 3.76 \times 11.5 = 43.24$$

The enthalpy of combustion for the 2 kmol of fuel becomes from Tbl 13.3

$H_P^o - H_R^o$ = (-46 352) 44.094 + (-45 714) 58.124 = - 4 700 925.6 kJ/2 kmol fuel

$$HV = -\overset{\circ}{H}_{RP} = \frac{4\ 700\ 925.6}{44.094 + 58.124} = \textbf{45 989 kJ/kg fuel}$$ Convert to mass basis

$\Delta H_P = 7 \times 33\ 397 + 9 \times 26\ 000 + 43.24 \times 21\ 463 = 1\ 395\ 839$ kJ/2 kmol fuel

The heat transfer for the two kmol of fuel is

$Q = H_R - H_P = -\overset{\circ}{H}_{RP} - \Delta H_P = 4\ 700\ 925.6 - 1\ 395\ 839$

= 3 305 087 kJ/2 kmol fuel

= **1 652 544 kJ/kmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.71

Blast furnace gas in a steel mill is available at 250°C to be burned for the generation of steam. The composition of this gas is, on a volumetric basis,

Component	CH_4	H_2	CO	CO_2	N_2	H_2O
Percent by volume	0.1	2.4	23.3	14.4	56.4	3.4

Find the lower heating value (kJ/m^3) of this gas at 250°C and ambient pressure.

Of the six components in the gas mixture, only the first 3 contribute to the heating value. These are, per kmol of mixture:

$$0.024\,H_2, \quad 0.001\,CH_4, \quad 0.233\,CO$$

For these components,

$$0.024\,H_2 + 0.001\,CH_4 + 0.233\,CO + 0.1305\,O_2 \rightarrow 0.026\,H_2O + 0.234\,CO_2$$

The remainder need not be included in the calculation, as the contributions to reactants and products cancel. For the lower HV(water as vapor) at 250°C

$$\bar{h}_{RP} = 0.026(-241\,826 + 7750) + 0.234(-393\,522 + 9370)$$
$$- 0.024(0 + 6558) - 0.001(-74\,873 + 2.254 \times 16.04(250-25))$$
$$- 0.233(-110\,527 + 6629) - 0.1305(0 + 6817)$$
$$= -72\,749 \ \frac{\text{kJ}}{\text{kmol fuel}}$$

$$\bar{v}_0 = \bar{R}\,T_o/P_o = 8.3145 \times 523.2/100 = 43.5015 \ \text{m}^3/\text{kmol}$$

LHV = +72 749 / 43.5015 = **1672 kJ/m^3**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.72

Consider natural gas A which are listed in Table 13.2. Calculate the enthalpy of combustion of each gas at 25°C, assuming that the products include vapor water. Repeat the answer for liquid water in the products.

Natural Gas A

$$0.939\,CH_4 + 0.036\,C_2H_6 + 0.012\,C_3H_8 + 0.013\,C_4H_{10}$$
$$+ 2.1485\,(O_2 + 3.76\,N_2) \rightarrow 1.099\,CO_2 + 2.099\,H_2O + 8.0784\,N_2$$

$$H_R = 0.939(-74\,878) + 0.036(-84\,740) + 0.012(-103\,900)$$
$$+ 0.013(-126\,200) = -76244 \text{ kJ}$$

a) vapor H_2O

$$H_P = 1.099(-393\,522) + 2.099(-241\,826) = -940\,074 \text{ kJ/kmol}$$

$$\bar{h}_{RP} = H_P - H_R = \mathbf{-863\,830\ kJ/kmol}$$

b) Liq. H_2O

$$H_P = 1.099(-393\,522) + 2.099(-285\,830) = -1\,032\,438$$

$$\bar{h}_{RP} = \mathbf{-956\,194\ kJ/kmol}$$

These values can be compared to the pure methane

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.73

Consider natural gas D which are listed in Table 13.2. Calculate the enthalpy of combustion of each gas at 25°C, assuming that the products include vapor water. Repeat the answer for liquid water in the products.

Natural Gas D:

$$0.543\,CH_4 + 0.163\,C_2H_6 + 0.162\,C_3H_8 + 0.074\,C_4H_{10}$$
$$+ 0.058\,N_2 + \nu_{O2}\,(O_2 + 3.76\,N_2)$$
$$\rightarrow\ 1.651\,CO_2 + 2.593\,H_2O + \nu_{O2} \times 3.76\,N_2$$

$$H_R = 0.543(-74\,873) + 0.163(-84\,740) + 0.162(-130\,900)$$
$$+ 0.074(-126\,200) = -80\,639\ kJ$$

a) vapor H_2O

$$H_P = 1.651(-393\,522) + 2.593(-241\,826) = -1\,276\,760\ kJ$$

$$\bar{h}_{RP} = \mathbf{-1\,196\,121\ kJ/kmol}$$

b) Liq. H_2O

$$H_P = 1.651(-393\,522) + 2.593(-285\,830) = -1\,390\,862\ kJ$$

$$\bar{h}_{RP} = \mathbf{-1\,310\,223\ kJ/kmol}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.74

A burner receives a mixture of two fuels with mass fraction 40% n-butane and 60% methanol, both vapor. The fuel is burned with stoichiometric air. Find the product composition and the lower heating value of this fuel mixture (kJ/kg fuel mix).

Since the fuel mixture is specified on a mass basis we need to find the mole fractions for the combustion equation. From Eq.13.4 we get

$$y_{butane} = (0.4/58.124) / [0.4/58.124 + 0.6/32.042] = 0.26875$$

$$y_{methanol} = 1 - y_{butane} = 0.73125$$

The reaction equation is

$$0.73125\, CH_3OH + 0.26875\, C_4H_{10} + \nu_{O2}\,(O_2 + 3.76\, N_2)$$

$$\rightarrow \nu_{CO2}\, CO_2 + \nu_{H2O} H_2O + 3.76\, \nu_{O2}\, N_2$$

C balance: $0.73125 + 4 \times 0.26875 = \nu_{CO2} = 1.80625$

H_2 balance: $2 \times 0.73125 + 5 \times 0.26875 = \nu_{H2O} = 2.80625$

O balance: $0.73125 + 2\, \nu_{O2} = 2\, \nu_{CO2} + \nu_{H2O} = 6.41875 \quad => \nu_{O2} = 2.84375$

Now the products are:

$$1.80625\, CO_2 + 2.80625\, H_2O + 10.6925\, N_2$$

Since the enthalpy of combustion is on a mass basis in table 13.3 (this is also the negative of the heating value) we get

LHV = $0.4 \times 45\,714 + 0.6 \times 21\,093$ = **30 941 kJ/kg fuel mixture**

Notice we took fuel vapor and water as vapor (lower heating value).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.75

Natural gas, we assume methane, is burned with 200% theoretical air and the reactants are supplied as gases at the reference temperature and pressure. The products are flowing through a heat exchanger where they give off energy to some water flowing in at 20°C, 500 kPa and out at 700°C, 500 kPa. The products exit at 400 K to the chimney. How much energy per kmole fuel can the products deliver and how many kg water per kg fuel can they heat?

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2} (O_2 + 3.76\ N_2) \rightarrow 2\ H_2O + 1\ CO_2 + c\ N_2$$

O balance: $2\ \nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2$

200% theoretical air: $\nu_{O2} = 2 \times 2 = 4$ so now more O_2 and N_2

$$CH_4 + 4 (O_2 + 3.76\ N_2) \rightarrow 2\ H_2O + 1\ CO_2 + 15.04\ N_2 + 2\ O_2$$

The products are cooled to 400 K (so we do not consider condensation) and the energy equation is

Energy Eq.: $H_R + Q = H_P = \overset{\circ}{H}_P + \Delta H_P = \overset{\circ}{H}_R + Q$

$$Q = \overset{\circ}{H}_P - \overset{\circ}{H}_R + \Delta H_P = \overset{\circ}{H}_{RP} + \Delta H_P$$

From Table 13.3: $\overset{\circ}{H}_{RP} = 16.04\ (-50\ 010) = -802\ 160$ kJ/kmol

$$\Delta H_P = \Delta \bar{h}^*_{CO2} + 2\ \Delta \bar{h}^*_{H2O} + 2\ \Delta \bar{h}^*_{O2} + 15.04\ \Delta \bar{h}^*_{N2}$$

From Table A.9

$$\Delta H_{P\ 400} = 4003 + 2 \times 3450 + 2 \times 3027 + 15.04 \times 2971 = 61\ 641 \text{ kJ/kmol}$$

$$Q = \overset{\circ}{H}_{RP} + \Delta H_P = -802\ 160 + 61\ 641 = \mathbf{-740\ 519\ kJ/kmol}$$

$$q_{prod} = -Q / M = 740\ 519 / 16.04 = 46\ 167 \text{ kJ/kg fuel}$$

The water flow has a required heat transfer, using B.1.3 and B.1.4 as

$$q_{H2O} = h_{out} - h_{in} = 3925.97 - 83.81 = 3842.2 \text{ kJ/kg water}$$

The mass of water becomes

$$m_{H2O} / m_{fuel} = q_{prod} / q_{H2O} = \mathbf{12.0\ kg\ water\ /\ kg\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.76

Liquid nitromethane is added to the air in a carburetor to make a stoichiometric mixture where both fuel and air are added at 298 K, 100 kPa. After combustion a constant pressure heat exchanger brings the products to 600 K before being exhausted. Assume the nitrogen in the fuel becomes N_2 gas. Find the total heat transfer per kmole fuel in the whole process.

$$CH_3NO_2 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 1.5\,H_2O + 1\,CO_2 + a\,N_2$$

C and H balances done in equation. The remaining

O balance: $2 + 2\,\nu_{O2} = 1.5 + 2 \quad \Rightarrow \quad \nu_{O2} = 0.75$

N balance: $1 + 3.76\,\nu_{O2} \times 2 = 2a \quad \Rightarrow \quad a = 3.32$

Energy eq.: $H_R + Q = H_P \quad \Rightarrow \quad Q = H_P - H_R = H_P^\circ - H_R^\circ + \Delta H_P - \Delta H_R$

The reactants enter at the reference state, $\Delta H_R = 0$, and the products at 600 K from table A.9

$$\Delta H_P = 1.5\,\Delta\bar{h}_{H_2O} + \Delta\bar{h}_{CO_2} + 3.32\,\Delta\bar{h}_{N_2}$$

$$= 1.5\,(10\,499) + 1\,(12\,906) + 3.32\,(8894) = 58\,183 \text{ kJ/kmol fuel}$$

$$H_P^\circ - H_R^\circ = H_{RP}^\circ = 61.04\,(-10\,537) = -643\,178 \text{ kJ/kmol}$$

$$Q = -643\,178 + 58\,183 = \mathbf{-584\,995 \text{ kJ/kmol fuel}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.77

Gasoline, C_7H_{17}, is burned in a steady state burner with stoichiometric air at P_o, T_o. The gasoline is flowing as a liquid at T_o to a carburetor where it is mixed with air to produce a fuel air gas mixture at T_o. The carburetor takes some heat transfer from the hot products to do the heating. After the combustion the products go through a heat exchanger, which they leave at 600 K. The gasoline consumption is 10 kg per hour. How much power is given out in the heat exchanger and how much power does the carburetor need?

Stoichiometric combustion:

$$C_7H_{17} + \nu_{O_2} (O_2 + 3.76\, N_2) \rightarrow 8.5\, H_2O + 7\, CO_2 + c\, N_2$$

O balance: $2\,\nu_{O_2} = 8.5 + 14 = 22.5 \quad \Rightarrow \quad \nu_{O_2} = 11.25$

N balance: $c = 3.76\ \nu_{O_2} = 3.76 \times 11.25 = 42.3$

$$M_{FUEL} = 7\, M_C + 17\, M_H = 7 \times 12.011 + 8.5 \times 2.016 = 101.213$$

C.V. Total, heat exchanger and carburetor included, Q out.

Energy Eq.: $H_R = \overset{\circ}{H}_R = \overset{\circ}{H}_P + \Delta H_P + Q_{out}$

From Table A.9

$$\Delta H_P = 8.5 \times 10\,499 + 7 \times 12\,906 + 42.3 \times 8894 = 555\,800 \text{ kJ/kmol}$$

From energy equation and Table 13.3

$$Q_{out} = \overset{\circ}{H}_R - \overset{\circ}{H}_P - \Delta H_P = -\overset{\circ}{H}_{RP} - \Delta H_P$$

$$= 101.213\,(44\,506) - 555\,800 = 3\,948\,786 \text{ kJ/kmol}$$

Now the power output is

$$\dot{Q} = \dot{n}\, Q_{out} = Q_{out}\, \dot{m}/M = 3\,948\,786 \times \frac{10}{3600} / 101.213 = \mathbf{108.4\ kW}$$

The carburetor air comes in and leaves at the same T so no change in energy, all we need is to evaporate the fuel, h_{fg} so

$$\dot{Q} = \dot{m}\, h_{fg} = \frac{10}{3600}\,(44\,886 - 44\,506) = \frac{1}{360} \times 380 = \mathbf{1.06\ kW}$$

Here we used Table 13.3 for fuel liquid and fuel vapor to get h_{fg} and any phase of the water as long as it is the same for the two.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.78

An isobaric combustion process receives gaseous benzene C_6H_6 and air in a stoichiometric ratio at P_o, T_o. To limit the product temperature to 2000 K, liquid water is sprayed in after the combustion. Find the kmol of liquid water added per kmol of fuel and the dew point of the combined products.

The reaction equation for stoichiometric mixture with C and H balance done is:

$$C_6H_6 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 3\,H_2O + 6\,CO_2 + c\,N_2$$

O balance: $2\,\nu_{O_2} = 3 + 6 \times 2 = 15 \quad \Rightarrow \quad \nu_{O_2} = 7.5$

N balance: $c = 3.76\ \nu_{O_2} = 3.76 \times 7.5 = 28.2$

With x kmol of water added per kmol fuel the products are
Products: $(3 + x)\,H_2O + 6\,CO_2 + 28.2\,N_2$

Energy Eq.: $H_R = H_R^\circ + x\,\bar{h}_{f\,H_2O\,liq}^\circ = H_P^\circ + \Delta H_P$

$$= H_P^\circ + x\,\bar{h}_{f\,H_2O\,vap}^\circ + (3 + x)\,\Delta\bar{h}_{H_2O} + 6\,\Delta\bar{h}_{CO_2} + 28.2\,\Delta\bar{h}_{N_2}$$

Where the extra water is shown explicitly. Rearrange to get

$$H_R^\circ - H_P^\circ - 6\Delta\bar{h}_{CO_2} - 28.2\Delta\bar{h}_{N_2} - 3\Delta\bar{h}_{H_2O}$$

$$= x\,(\bar{h}_{f\,H_2O\,vap}^\circ - \bar{h}_{f\,H_2O\,liq}^\circ + \Delta\bar{h}_{H_2O})$$

$$40\,576 \times 78.114 - 6 \times 91\,439 - 28.2 \times 56\,137 - 3 \times 72\,788$$

$$= x\,[-241\,826 - (-285\,830) + 72\,788]$$

$$819\,493 = x\,(116\,792) \Rightarrow \quad x = \mathbf{7.017\ kmol/kmol\ fuel}$$

Dew point: $y_v = \dfrac{3 + x}{6 + 28.2 + 3 + x} = 0.2265$

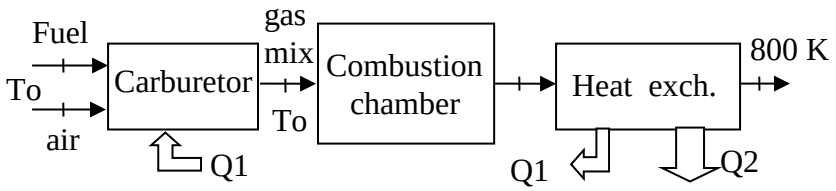
$\Rightarrow P_v = y_v P = 0.2265 \times 101.325 = 22.95$ kPa

B.1.2: $T_{dew} = \mathbf{63^oC}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.79

A liquid fuel similar to diesel, n-dodecane $C_{12}H_{26}$, is sent into a carburetor, where it is vaporized and mixed with air in a stoichiometric ratio. The liquid fuel and air are supplied at T_o and 100 kPa, and the heat to the carburetor, Q_1, is taken from the combustion products, as in Fig. P13.77. After mixing, the reactant gas goes through a combustor, and after complete combustion the products enter a heat exchanger, where they deliver Q_1 to the carburetor and Q_2 to an application, after which the products exit at 800 K. Find the heat transfer to the carburetor per kmol fuel, Q_1, and the second heat transfer, Q_2, both in kJ/kmol fuel..



First do the combustion equation for n-Dodecane $C_{12}H_{26}$

$$C_{12}H_{26} + \nu_{O_2}(O_2 + 3.76\, N_2) \Rightarrow 12\, CO_2 + 13\, H_2O + 69.56\, N_2$$

O balance: $2\nu_{O_2} = 12 \times 2 + 13 = 37 \quad \Rightarrow \quad \nu_{O_2} = 37/2 = 18.5$

N_2 balance: $\nu_{O_2} = 3.76 \;\; \nu_{O_2} = 3.76 \times 18.5 = 69.56$

$$M_{FUEL} = 12\, M_C + 26\, M_H = 12 \times 12.011 + 26 \times 1.008 = 170.34$$

CV Carburetor, here the air is unchanged, liquid fuel vaporizes

$$Q_1 = HV_{f\,vap} - HV_{f\;liq} = 170.34(44\,467 - 44\,109) = 60\,982 \text{ kJ/kmol}$$

CV Total system (notice Q_1 is internal to this CV).

Energy Eq.: $0 = H_{R1} - H_{P2} - Q_2$

Table 13.3: $HV = -\overset{\circ}{H}_{RP} = -170.34\,(-44\,109) = 7\,513\,527$ kJ/kmol

Table A.9: $\Delta H_{P2} = 12\, \Delta\bar{h}_{CO2} + 13\, \Delta\bar{h}_{H2O} + 69.56\, \Delta\bar{h}_{N2}$

$$= 12 \times 22\,806 + 13 \times 18\,002 + 69.56 \times 15\,046 = 1\,554\,298 \text{ kJ/kmol}$$

$$Q_2 = H_{R1} - H_{P2} = H_R^o - H_P^o - \Delta H_{P2} = HV - \Delta H_{P2}$$

$$= 7\,513\,527 - 1\,554\,298 = \mathbf{5\,959\,229\ kJ/kmol}$$

13.80

A mixture of fuels is E85, which is 85% ethanol and 15% gasoline (assume octane) by mass. Assume we put the fuel and air, both at T_o, P_o, into a carburetor and vaporize the fuel as we mix it with stoichiometric air before it flows to an engine. Assume the engine has an efficiency as work divided by the lower heating value of 30%, and we want it to deliver 40 kW. We use heat from the exhaust flow (500 K) for the carburetor. Find the lower heating value of this fuel (kJ/kg), the rate of fuel consumption, the heating rate needed in the carburetor, and the rate of entropy generation in the carburetor.

The heating value of the liquid fuel blend becomes

$$LHV = 0.85\ LHV_{ethanol} + 0.15\ LHV_{octane}$$
$$= 0.85 \times 26\,811 + 0.15 \times 44\,425 \quad kJ/kg = \mathbf{29\,453\ kJ/kg}$$

$$\dot{W} = 0.3\ \dot{m}_{fuel}\ LHV$$

$$\dot{m}_{fuel} = \dot{W}/(0.3 \times LHV) = 40\ kW/\ (0.3 \times 29\,453\ kJ/kg)$$
$$= \mathbf{0.004527\ kg/s = 16.3\ kg/h}$$

The difference in heating value based on liquid versus vapor fuel is

$$\Delta LHV = 0.85\ (27\,731 - 26\,811) + 0.15\ (44\,788 - 44\,425)$$
$$= 0.85 \times 920 + 0.15 \times 363 = 836.45\ kJ/kg$$

$$\dot{Q} = \dot{m}_{fuel}\ \Delta LHV = 0.004527 \times 836.45 = 3.79\ kW$$

Entropy generation is from vaporizing the fuel by transfer of heat from 500 K exhaust gas to the intake system at To and then mixing it with air. The mole fractions are

Ethanol: M = 46.069; Octane: M = 114.232

$$DIV = [0.85 / 46.069] + [0.15 /114.232] = 0.01845 + 0.001313 = 0.019764$$
$$y_{ethanol} = 0.01845 / 0.019764 = 0.9336$$
$$y_{octane} = 1 - y_{ethanol} = 0.06644$$

$$0.93356\ C_2H_5OH + 0.06644\ C_8H_{18} + 3.63118\ (O_2 + 3.76\ N_2) \Rightarrow$$
$$2.39864\ CO_2 + 3.39864\ H_2O + 13.65324\ N_2$$

C balance: $0.93356 \times 2 + 0.06644 \times 8 = 2.39864 = \nu_{CO2}$

H balance: $0.93356 \times 6 + 0.06644 \times 18 = 6.79728 = 2\nu_{H2O}$

So the A/F ratio on a mole and mass basis are

A/F-mole = $3.63118 \times 4.76 / 1 = 17.2844$;

A/F-mass = $17.2844 \times 28.97/50.5996 = 9.896$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

The fuel was mixed before the carburetor so afterwards we have a 1: 17.2844 mix.

$$s_{fg\ ethanol} = (282.444 - 160.554)/46.069 = 2.6458 \text{ kJ/kg-K}$$
$$s_{fg\ octane} = (466.514 - 360.575)/114.232 = 0.927402 \text{ kJ/kg-K}$$
$$s_{fg\ fuel\ mix} = 0.85 \times 2.6458 + 0.15 \times 0.927 = 2.38798 \text{ kJ/kg-K}$$
$$M_{fuel} = 0.9336 \times 46.069 + 0.06644 \times 114.232 = 50.5996$$

Entropy Eq.: $\dot{S}_{gen} = \text{out} - \text{in} = \dot{m}_{fuel}\,[s_{fg} - R \ln(y_{fuel})] + \dot{m}_{air}\,[- R \ln(y_{air})] - \dot{Q}/T_{exhaust}$

$$= 0.004527 \times \left[2.38798 - \frac{8.3145}{50.5996} \ln\left(\frac{1}{18.2844}\right)\right]$$
$$- 0.004527 \times 9.896 \times 0.287 \ln\left(\frac{17.2844}{18.2844}\right) - \frac{3.79}{500} \text{ kW/K}$$
$$= 0.01297 + 0.000723 - 0.00758 = \mathbf{0.0061\ kW/K}$$

Adiabatic Flame Temperature

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.81

In a rocket, hydrogen is burned with air, both reactants supplied as gases at P_o, T_o. The combustion is adiabatic and the mixture is stoichiometeric (100% theoretical air). Find the products dew point and the adiabatic flame temperature (~2500 K).

The reaction equation is:

$$H_2 + \nu_{O2} (O_2 + 3.76\ N_2) \Rightarrow H_2O + 3.76\ \nu_{O2}\ N_2$$

The balance of hydrogen is done, now for oxygen we need $\nu_{O2} = 0.5$ and thus we have 1.88 for nitrogen.

$$y_v = 1/(1+1.88) = 0.3472 \Rightarrow P_v = 101.325 \times 0.3472 = 35.18 \text{ kPa} = P_g$$

Table B.1.2: $\mathbf{T_{dew} = 72.6\ C.}$

Energy Eq:

$$H_R = H_P \Rightarrow 0 = -241\,826 + \Delta h_{water} + 1.88\ \Delta h_{nitrogen}$$

$$\Delta H_P = \Delta h_{water} + 1.88\ \Delta h_{nitrogen} = 241\,826 \text{ kJ/kmol fuel}$$

Find now from table A.9 the two enthalpy terms

At 2400 K : $\Delta H_P = 93741 + 1.88 \times 70640 = 226544$ kJ/kmol fuel

At 2600 K : $\Delta H_P = 104520 + 1.88 \times 77963 = 251090$ kJ/kmol fuel

Then interpolate to hit 241 826 to give **T = 2525 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.82

Hydrogen gas is burned with pure oxygen in a steady flow burner where both reactants are supplied in a stoichiometric ratio at the reference pressure and temperature. What is the adiabatic flame temperature?

The reaction equation is:

$$H_2 + \nu_{O2}\, O_2 \quad => \quad H_2O$$

The balance of hydrogen is done, now for oxygen we need $\nu_{O2} = 0.5$.

Energy Eq.: $H_R = H_P$ => $0 = -241\,826 + \Delta\bar{h}_{H2O}$

=> $\Delta\bar{h}_{H2O} = 241\,826$ kJ/kmol

Interpolate now in table A.9 for the temperature to give this enthalpy

T = 4991 K

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.83

Some type of wood can be characterized as $C_1H_{1.5}O_{0.7}$ with a lower heating value of 19 500 kJ/kg. Find its adiabatic flame temperature when burned with stoichiometric air at 100 kPa, 298 K.

$$C_1H_{1.5}O_{0.7} + \nu_{O_2}[\, O_2 + 3.76\, N_2\,] \rightarrow \quad CO_2 + 0.75\, H_2O + 3.76\nu_{O_2}\, N_2$$

O balance: $0.7 + 2\nu_{O_2} = 2 + 0.75 \quad \Rightarrow \quad \nu_{O_2} = 1.025,\ \nu_{N2} = 3.854$

$$M = 1 \times 12.0111 + 1.5 \times 1.008 + 0.7 \times 16 = 24.712$$

$$\overset{\circ}{H}_{RP} = H_P^o - H_R^o = -M \times HV = -24.712 \times 19\,500 = -481\,884 \text{ kJ/kmol}$$

Energy Eq.: $H_p = \overset{\circ}{H}_P + \Delta H_p = H_R = \overset{\circ}{H}_R \quad \Rightarrow \quad \Delta H_p = \overset{\circ}{H}_R - \overset{\circ}{H}_P = -\overset{\circ}{H}_{RP}$

$$\Delta H_P = \Delta\bar{h}_{CO2} + 0.75\, \Delta\bar{h}_{H2O} + 3.854\, \Delta\bar{h}_{N2} = 481\,884 \text{ kJ/kmol}$$

at 2400 K: $\Delta H_P = 115\,779 + 0.75 \times 93\,741 + 3.854 \times 70\,640 = 458\,331$ kJ

at 2600 K: $\Delta H_P = 128\,074 + 0.75 \times 104\,520 + 3.854 \times 77\,963 = 506\,933$ kJ

$$T = 2400 + 200\, \frac{481\,884 - 458\,331}{506\,933 - 458\,331} = \mathbf{2497\ K}$$

Comment: Most wood has some water and some non-combustible solids material so the actual flame temperature will be much lower.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.84

A gas turbine burns methane with 200% theoretical air. The air and fuel comes in through two separate compressors bringing them from 100 kPa, 298 K to 1400 kPa and after mixing enters the combustion chamber at 600 K. Find the adiabatic flame temperature using constant specific heat for the ΔH_P terms.

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2} (O_2 + 3.76\ N_2) \rightarrow 2\ H_2O + 1\ CO_2 + c\ N_2$$

O balance: $2\ \nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2$

200% theoretical air: $\nu_{O2} = 2 \times 2 = 4$ so now more O_2 and N_2

$$CH_4 + 4 (O_2 + 3.76\ N_2) \rightarrow 2\ H_2O + 1\ CO_2 + 15.04\ N_2 + 2\ O_2$$

The energy equation around the combustion chamber becomes

Energy Eq.: $H_P - H_R = 0 \quad \Rightarrow \quad \Delta H_P = \overset{\circ}{H}_R + \Delta H_R - \overset{\circ}{H}_P = -\overset{\circ}{H}_{RP} + \Delta H_R$

$\Delta H_R = \Delta H_{Fuel} + \Delta H_{air} = M\ C_P\ \Delta T + 4(\Delta \bar{h}_{O2} + 3.76\ \Delta \bar{h}_{N2})$

$= 16.043 \times 2.254\ (600–298) + 4(9245 + 3.76 \times 8894) = 181\ 666$ kJ/kmol

$-\overset{\circ}{H}_{RP} = 16.043 \times 50\ 010 = 802\ 310$ kJ/kmol

$\Delta H_P = \Delta \bar{h}_{CO2} + 2\ \Delta \bar{h}_{H2O} + 15.04\ \Delta \bar{h}_{N2} + 2\ \Delta \bar{h}_{O2} \approx \Delta T \sum \nu_i \bar{C}_{Pi}$

$= 802\ 310 + 181\ 666 = 983\ 976$ kJ/kmol (from energy Eq.)

$\sum \nu_i \bar{C}_{Pi} = 0.842 \times 44.01 + 2 \times 1.872 \times 18.015 + 15.04 \times 1.042 \times 28.013$

$+ 2 \times 0.922 \times 31.999 = 602.52$ kJ/kmol-K

$\Delta T = \Delta H_P / \sum \nu_i \bar{C}_{Pi} = 983\ 976 / 602.52 = 1633.1$ K

T = 298 + 1633 = **1931 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.85

Extend the solution to the previous problem by using Table A.9 for the ΔH_P terms.

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2} (O_2 + 3.76\ N_2) \rightarrow 2\ H_2O + 1\ CO_2 + c\ N_2$$

O balance: $2\ \nu_{O2} = 2 + 2 \quad => \quad \nu_{O2} = 2$

200% theoretical air: $\nu_{O2} = 2 \times 2 = 4$ so now more O_2 and N_2

$$CH_4 + 4 (O_2 + 3.76\ N_2) \rightarrow 2\ H_2O + 1\ CO_2 + 15.04\ N_2 + 2\ O_2$$

The energy equation around the combustion chamber becomes

Energy Eq.: $H_P - H_R = 0 \quad => \quad \Delta H_P = \overset{\circ}{H}_R + \Delta H_R - \overset{\circ}{H}_P = -\overset{\circ}{H}_{RP} + \Delta H_R$

$\Delta H_R = \Delta H_{Fuel} + \Delta H_{air} = M\ C_P\ \Delta T + 4(\Delta \bar{h}_{O2} + 3.76\ \Delta \bar{h}_{N2})$

$= 16.043 \times 2.254\ (600–298) + 4(9245 + 3.76 \times 8894) = 181\ 666$ kJ/kmol

$-\overset{\circ}{H}_{RP} = 16.043 \times 50\ 010 = 802\ 310$ kJ/kmol

$\Delta H_P = \Delta \bar{h}_{CO2} + 2\ \Delta \bar{h}_{H2O} + 15.04\ \Delta \bar{h}_{N2} + 2\ \Delta \bar{h}_{O2}$

$= 802\ 310 + 181\ 666 = 983\ 976$ kJ/kmol (from energy Eq.)

Trial and error with $\Delta \bar{h}$ from Table A.9

At 1800 K

$\Delta H_P = 79\ 432 + 2 \times 62\ 693 + 15.04 \times 48\ 979 + 2 \times 51\ 674 = 1\ 044\ 810$ kJ/kmol

At 1700 K

$\Delta H_P = 73\ 480 + 2 \times 57\ 757 + 15.04 \times 45\ 430 + 2 \times 47\ 959 = 968\ 179$ kJ/kmol

Linear interpolation: $T = 1700 + 100 \dfrac{983\ 976 - 968\ 179}{1\ 044\ 810 - 968\ 179} =$ **1721 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.86

Carbon is burned with air in a furnace with 150% theoretical air and both reactants are supplied at the reference pressure and temperature. What is the adiabatic flame temperature?

$$C + \nu_{O_2} O_2 + 3.76\, \nu_{O_2} N_2 \rightarrow 1\, CO_2 + 3.76\, \nu_{O_2} N_2$$

From this we find $\nu_{O_2} = 1$ and the actual combustion reaction is

$$C + 1.5\, O_2 + 5.64\, N_2 \rightarrow 1\, CO_2 + 5.64\, N_2 + 0.5\, O_2$$

$$H_P = \overset{\circ}{H}_P + \Delta H_P = H_R = \overset{\circ}{H}_R \quad \Rightarrow$$

$$\Delta H_P = \overset{\circ}{H}_R - \overset{\circ}{H}_P = 0 - (-393\,522) = 393\,522 \text{ kJ/kmol}$$

$$\Delta H_P = \Delta \bar{h}_{CO2} + 5.64\, \Delta \bar{h}_{N2} + 0.5\, \Delta \bar{h}_{O2}$$

Find T so ΔH_P takes on the required value. To start guessing assume all products are nitrogen (1 + 5.64 + 0.5 = 7.14) that gives $1900 < T < 2000$ K from Table A.9.

$$\Delta H_{P\,1900} = 85\,420 + 5.64 \times 52\,549 + 0.5 \times 55\,414 = 409\,503 \quad \text{too high}$$
$$\Delta H_{P\,1800} = 79\,432 + 5.64 \times 48\,979 + 0.5 \times 51\,674 = 381\,511$$

Linear interpolation to find

$$T = 1800 + 100\, \frac{393\,522 - 381\,511}{409\,503 - 381\,511} = \mathbf{1843\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.87

Acetylene gas at 25°C, 100 kPa is fed to the head of a cutting torch. Calculate the adiabatic flame temperature if the acetylene is burned with

a. 100% theoretical air at 25°C.

b. 100% theoretical oxygen at 25°C.

a) $C_2H_2 + 2.5\,O_2 + 2.5 \times 3.76\,N_2 \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$

$H_R = \bar{h}^o_{f\,C2H2} = +226\,731$ kJ/kmol from table A.10

$H_P = 2(-393\,522 + \Delta\bar{h}^*_{CO2}) + 1(-241\,826 + \Delta\bar{h}^*_{H2O}) + 9.4\,\Delta\bar{h}^*_{N2}$

$Q_{CV} = H_P - H_R = 0 \Rightarrow 2\,\Delta\bar{h}^*_{CO2} + 1\,\Delta\bar{h}^*_{H2O} + 9.4\,\Delta\bar{h}^*_{N2} = 1\,255\,601$ kJ

Trial and Error A.9: $LHS_{2800} = 1\,198\,369$, $LHS_{3000} = 1\,303\,775$

Linear interpolation: $T_{PROD} =$ **2909 K**

b) $C_2H_2 + 2.5\,O_2 \rightarrow 2\,CO_2 + H_2O$

$H_R = +226\,731$ kJ ; $H_P = 2(-393\,522 + \Delta\bar{h}^*_{CO2}) + 1(-241\,826 + \Delta\bar{h}^*_{H2O})$

$\Rightarrow 2\,\Delta\bar{h}^*_{CO2} + 1\,\Delta\bar{h}^*_{H2O} = 1\,255\,601$ kJ/kmol fuel

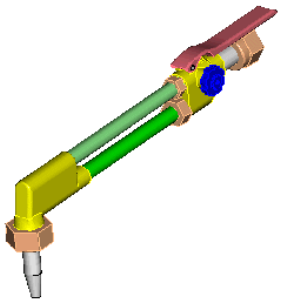
At 6000 K (limit of A.9) $2 \times 343\,782 + 302\,295 = 989\,859$

At 5600 K $2 \times 317\,870 + 278\,161 = 913\,901$

Slope 75 958/400 K change

Extrapolate to cover the difference above 989 859 kJ/kmol fuel

$T_{PROD} \approx 6000 + 400(265\,742/75\,958) \approx$ **7400 K**



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.88

Hydrogen gas is burned with 200% theoretical air in a steady flow burner where both reactants are supplied at the reference pressure and temperature. What is the adiabatic flame temperature?

The stoichiometric reaction equation is:

$$H_2 + \nu_{O2} (O_2 + 3.76\ N_2) \Rightarrow H_2O + 3.76\ \nu_{O2}\ N_2$$

The balance of hydrogen is done, now for oxygen we need $\nu_{O2} = 0.5$ and thus we have for the actual mixture $\nu_{O2} = 1$. The actual reaction is

$$H_2 + 1\ (O_2 + 3.76\ N_2) \Rightarrow 1\ H_2O + 3.76\ N_2 + 0.5\ O_2$$

The energy equation with formation enthalpy from A.9 or A.10 for water is

$$H_R = H_P \quad \Rightarrow \quad 0 = -241\ 826 + \Delta H_P$$

$$\Delta H_P = \Delta h_{H2O} + 3.76\ \Delta h_{N2} + 0.5\ \Delta h_{O2} = +241\ 826\ \text{kJ/kmol}$$

Find now from table A.9 the three enthalpy terms

At 2000 K : $\Delta H_P = 72\ 788 + 3.76 \times 56\ 137 + 0.5 \times 59\ 176 = 313\ 451$

At 1800 K : $\Delta H_P = 62\ 693 + 3.76 \times 48\ 979 + 0.5 \times 51\ 674 = 272\ 691$

At 1600 K : $\Delta H_P = 52\ 907 + 3.76 \times 41\ 904 + 0.5 \times 44\ 267 = 232\ 600$

At 1700 K : $\Delta H_P = 57\ 757 + 3.76 \times 45\ 430 + 0.5 \times 47\ 959 = 252\ 553$

Then interpolate to match 241 826 to give

$$T = 1600 + 100\ \frac{241\ 826 - 232\ 600}{252\ 553 - 232\ 600} = \mathbf{1646\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.89

Butane gas at 25°C is mixed with 150% theoretical air at 600 K and is burned in an adiabatic steady flow combustor. What is the temperature of the products exiting the combustor?

$$C_4H_{10} + 1.5\times6.5\,(O_2 + 3.76\,N_2) \rightarrow 4\,CO_2 + 5\,H_2O + 3.25\,O_2 + 36.66\,N_2$$

Energy Eq.: $H_P - H_R = 0$ => $\Delta H_P = H_R^\circ + \Delta H_R - H_P^\circ$

Reactants: $\Delta H_R = 9.75(9245) + 36.66(8894) = 416\,193$ kJ/kmol ;

$H_R^\circ = \bar{h}_{C4H10} = \bar{h}_{f\,IG}^{o} = -126\,200$ kJ/kmol => $H_R = +289\,993$ kJ/kmol

$H_P^\circ = 4(-393522) + 5(-241826) = -2\,783\,218$ kJ/kmol

$\Delta H_P = 4\,\Delta\bar{h}_{CO2}^{*} + 5\,\Delta\bar{h}_{H2O}^{*} + 3.25\,\Delta\bar{h}_{O2}^{*} + 36.66\,\Delta\bar{h}_{N2}^{*}$

From the energy equation we then get

$\Delta H_P = -126\,200 + 416\,193 - (-2\,783\,218) = 3\,073\,211$ kJ/kmol

Trial and Error:

$LHS_{2000\,K} = 2\,980\,000,$
$LHS_{2200\,K} = 3\,369\,866$

Linear interpolation to match RHS

=> $T_P =$ **2048 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.90

A stoichiometric mixture of benzene, C_6H_6, and air is mixed from the reactants flowing at 25°C, 100 kPa. Find the adiabatic flame temperature. What is the error if constant specific heat at T_0 for the products from Table A.5 are used?

$$C_6H_6 + \nu_{O_2} O_2 + 3.76\, \nu_{O_2} N_2 \rightarrow 6CO_2 + 3H_2O + 3.76\, \nu_{O_2} N_2$$

$$\nu_{O_2} = 6 + 3/2 = 7.5 \quad \Rightarrow \quad \nu_{N_2} = 28.2$$

$$H_P = \overset{\circ}{H}_P + \Delta H_P = H_R = \overset{\circ}{H}_R \quad \Rightarrow$$

$$\Delta H_P = -\overset{\circ}{H}_{RP} = 40576 \times 78.114 = 3\,169\,554 \text{ kJ/kmol}$$

$$\Delta H_P = 6\, \Delta\bar{h}_{CO2} + 3\, \Delta\bar{h}_{H2O} + 28.2\, \Delta\bar{h}_{N2}$$

$$\Delta H_{P\ 2600K} = 6(128074) + 3(104\,520) + 28.2(77\,963) = 3\,280\,600,$$

$$\Delta H_{P\ 2400K} = 6(115\,779) + 3(93\,741) + 28.2(70\,640) = 2\,968\,000$$

Linear interpolation $\Rightarrow$ $T_{AD} =$ **2529 K**

$$\sum \nu_i \bar{C}_{Pi} = 6 \times 0.842 \times 44.01 + 3 \times 1.872 \times 18.015 + 28.2 \times 1.042 \times 28.013$$

$$= 1146.66 \text{ kJ/kmol K}$$

$$\Delta T = \Delta H_P / \sum \nu_i \bar{C}_{Pi} = 3\,169\,554 / 1146.66 = 2764$$

$\Rightarrow$ $T_{AD} = 3062$ K, **21% high**

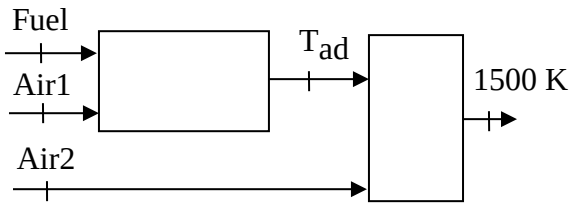
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.91

What is the adiabatic flame temperature before the secondary air is added in Problem 13.51

$$CH_4 + \nu(O_2 + 3.76\ N_2) \rightarrow$$
$$CO_2 + 2H_2O + 3.76\ \nu\ N_2$$

O balance: $\nu = 2$, $\nu_{N2} = 7.52$



Do a C.V. around the combustion chamber, then the energy equation becomes

Energy Eq.: $H_{R1} = H_{P\,1} = H_P^\circ + \Delta H_{P\,1}$

$$H_{R1} = H_R^\circ + \Delta H_{R1} = \bar{h}_{f\,fuel}^{\,o} + \Delta H_{Fuel} + \Delta H_{air1}$$

$$\Delta H_{air1} = 2(\Delta H_{O2} + 3.76\ \Delta H_{N2}) = 2(6086 + 3.76 \times 5911) = 56\ 623\ \text{kJ/kmol}$$

$$\Delta H_{Fuel} \approx M\ C_P\ \Delta T = 16.043 \times 2.254\ (500 - 298) = 7304.5\ \text{kJ/kmol}$$

$$\bar{h}_{f\,fuel}^{\,o} - H_P^\circ = HV = 16.043 \times 50\ 010 = 802\ 310\ \text{kJ/kmol}$$

$$\Delta H_{P\,1} = \Delta\bar{h}_{CO2} + 0.75\ \Delta\bar{h}_{H2O} + 3.854\ \Delta\bar{h}_{N2}$$
$$= \bar{h}_{f\,fuel}^{\,o} + \Delta H_{Fuel} + \Delta H_{air1} - H_P^\circ \quad \text{(from energy Eq.)}$$
$$= 802\ 310 + 7304.5 + 56\ 623 = 866\ 237\ \text{kJ/kmol fuel}$$

at 2400 K: $\Delta H_{P\,1} = 115\ 779 + 2 \times 93\ 741 + 7.52 \times 70\ 640 = 834\ 474$ kJ/kmol

at 2600 K: $\Delta H_{P\,1} = 128\ 074 + 2 \times 104\ 520 + 7.52 \times 77\ 963 = 923\ 396$ kJ/kmol

$$T = 2400 + 200\ \frac{866\ 237 - 834\ 474}{923\ 396 - 834\ 474} = \mathbf{2471\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.92

Ethene, C_2H_4, burns with 150% theoretical air in a steady flow constant-pressure process with reactants entering at P_0, T_0. Find the adiabatic flame temperature.

Stoichiometric

$$C_2H_4 + 3(O_2 + 3.76N_2) \rightarrow 2CO_2 + 2H_2O + 11.28N_2$$

Actual

$$C_2H_4 + 4.5(O_2 + 3.76N_2) \rightarrow 2CO_2 + 2H_2O + 1.5\ O_2 + 16.92N_2$$

$$H_P = \overset{\circ}{H}_P + 2\Delta\bar{h}_{CO_2} + 2\Delta\bar{h}_{H_2O} + 1.5\Delta\bar{h}_{O_2} + 16.92\Delta\bar{h}_{N_2}$$

$$\overset{\circ}{H}_R = \bar{h}^{\circ}_{f\ Fu} \qquad\qquad \Delta H_P + \overset{\circ}{H}_P = \overset{\circ}{H}_R$$

$$\Rightarrow \Delta H_P = -\overset{\circ}{H}_{RP} = 28.054 \times 47\ 158 = 1\ 322\ 970.5\ \frac{\text{kJ}}{\text{kmol Fu}}$$

$$\Delta H_P = 2\Delta\bar{h}_{CO_2} + 2\Delta\bar{h}_{H_2O} + 1.5\Delta\bar{h}_{O_2} + 16.92\Delta\bar{h}_{N_2}$$

Initial guess based on (2+2+1.5+16.92) N_2 from A.9: $T_1 = 2100$ K

$$\Delta H_P(2000) = 1\ 366\ 982, \qquad \Delta H_P(1900) = 1\ 278\ 398$$

$$\Rightarrow \quad \mathbf{T_{AD} \cong 1950\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.93

A special coal burner uses a stoichiometric mixture of coal and an oxygen - argon mixture (1:1 mole ratio) with the reactants supplied at Po, To. Find the adiabatic flame temperature assuming complete combustion.

Combustion of carbon:

$$C + O_2 + Ar \rightarrow CO_2 + Ar$$

C.V. Combustion chamber.

Energy Eq.:

$$H_R = \overset{\circ}{H}_R = H_P = \overset{\circ}{H}_P + \Delta H_P = \bar{h}_{f\,CO_2} + \Delta\bar{h}_{CO_2} + \Delta\bar{h}_{Ar}$$

Table A.9 or A.10: $\bar{h}_{f\,CO_2} = -393\,522$ kJ/kmol, reference $\overset{\circ}{H}_R = 0$

Table A.5: $\bar{C}_{P\,Ar} = 0.52 \times 39.948 = 20.773$ kJ/kmol-K

$$\Delta H_P = \overset{\circ}{H}_R - \overset{\circ}{H}_P = 0 - \bar{h}_{f\,CO_2} = 393\,522 \text{ kJ/kmol fuel}$$

$$\Delta H_{P\,5200} = 292\,112 + 20.773 \times (5200 - 298) = 393\,938 \text{ kJ/kmol fuel},$$

$$\Delta H_{P\,4800} = 266\,488 + 20.773 \times (4800 - 298) = 360\,005 \text{ kJ/kmol fuel},$$

interpolate $\Rightarrow$ $T_4 = T_{ad.flame} =$ **5195 K**

Comment: At this temperature some chemical equilibrium reactions will be important, see Chapter 14.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.94

A gas-turbine burns natural gas (assume methane) where the air is supplied to the combustor at 1000 kPa, 500 K and the fuel is at 298 K, 1000 kPa. What is the equivalence ratio and the percent theoretical air if the adiabatic flame temperature should be limited to 1800 K?

The reaction equation for a mixture with excess air is:

$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + 3.76\nu_{O2}\,N_2 + (\nu_{O2} - 2)O_2$$

$$H_P = H_P^\circ + \Delta H_P = H_R = H_R^\circ + \Delta H_R$$

From table A.9 at 500 K (notice fuel is at 298 K)

$$\Delta H_R = 0 + \nu_{O2}(\Delta h_{O2} + 3.76\,\Delta h_{N2}) = \nu_{O2}(6086 + 3.76 \times 5911) = 28\,311.4\,\nu_{O2}$$

From table A.9 at 1800 K:

$$\Delta H_P = 2\,\Delta h_{H2O} + \Delta h_{CO2} + 3.76\,\nu_{O2}\,\Delta h_{N2} + (\nu_{O2} - 2)\,\Delta h_{O2}$$

$$= 2 \times 62\,693 + 79432 + 3.76\,\nu_{O2} \times 48\,979 + (\nu_{O2} - 2)\,51\,674$$

$$= 101\,470 + 235\,835\,\nu_{O2}$$

From table 13.3: $H_P^\circ - H_R^\circ = H_{RP}^\circ = 16.04(-50\,010) = -802\,160$ kJ/kmol

Now substitute all terms into the energy equation

$$-802\,160 + 101\,470 + 235\,835\,\nu_{O2} = 28\,311.4\,\nu_{O2}$$

Solve for ν_{O2}

$$\nu_{O2} = \frac{802\,160 - 101\,470}{235\,835 - 28\,311.4} = 3.376$$

%Theoretical air = 100 (3.376 / 2) = **168.8 %**

Φ = AFs / AF = 2 / 3.376 = **0.592**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.95

Liquid butane at 25°C is mixed with 150% theoretical air at 600 K and is burned in a steady flow burner. Use the enthalpy of combustion from Table 13.3 to find the adiabatic flame temperature out of the burner.

$$C_4H_{10} + 1.5\times6.5\,(O_2 + 3.76\,N_2) \rightarrow 4\,CO_2 + 5\,H_2O + 3.25\,O_2 + 36.66\,N_2$$

Energy Eq.: $H_P - H_R = 0$ => $\Delta H_P = H^\circ_R + \Delta H_R - H^\circ_P = -H^\circ_{RP} + \Delta H_R$

Reactants: $\Delta H_R = 9.75(9245) + 36.66(8894) = 416\,193$ kJ/kmol;

$$H^\circ_{RP} = M \times HV = 58.124 \times (-45\,344) = -2\,635\,575 \text{ kJ/kmol}$$

$$\Delta H_P = 4\Delta\bar{h}^*_{CO2} + 5\Delta\bar{h}^*_{H2O} + 3.25\,\Delta\bar{h}^*_{O2} + 36.66\,\Delta\bar{h}^*_{N2}$$

So the energy equation becomes

$$\Delta H_P = 2\,635\,575 + 416\,193 = 3\,051\,768 \text{ kJ/kmol}$$

Trial and Error:

$$\Delta H_{P\ 2000\ K} = 4\times 91439 + 5\times 72788 + 3.25\times 59176 + 36.66\times 56137$$
$$= 2\,980\,000,$$
$$\Delta H_{P\ 2200\ K} = 4\times 103562 + 5\times 83153 + 3.25\times 66770 + 36.66\times 63362$$
$$= 3\,369\,866$$

Linear interpolation to match RHS => T_P = **2037 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.96

Natural gas, we assume methane, is burned with 200% theoretical air and the reactants are supplied as gases at the reference temperature and pressure. The products are flowing through a heat exchanger and then out the exhaust, as in Fig. P13.96. What is the adiabatic flame temperature right after combustion before the heat exchanger?

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2} (O_2 + 3.76\ N_2) \rightarrow 1\ CO_2 + 2\ H_2O + c\ N_2$$

O balance: $2\ \nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2$

200% theoretical air: $\nu_{O2} = 2 \times 2 = 4$ so now more O_2 and N_2

$$CH_4 + 4 (O_2 + 3.76\ N_2) \rightarrow 1\ CO_2 + 2\ H_2O + 15.04\ N_2 + 2\ O_2$$

Energy Eq.: $H_{air} + H_{fuel} = H_R = H_P$

$$H_P^\circ + \Delta H_P = H_R^\circ + \Delta H_R \quad \Rightarrow \quad \Delta H_P = H_R^\circ + \Delta H_R - H_P^\circ = -H_{RP}^\circ + 0$$

From Table 13.3: $-H_{RP}^\circ = -16.04\ (-50\ 010) = 802\ 160$ kJ/kmol

$$\Delta H_P = \Delta \bar{h}^*_{CO2} + 2\ \Delta \bar{h}^*_{H2O} + 2\ \Delta \bar{h}^*_{O2} + 15.04\ \Delta \bar{h}^*_{N2}$$

From Table A.9

$$\Delta H_{P\ 1600} = 67\ 659 + 2 \times 52\ 907 + 2 \times 44\ 267 + 15.04 \times 41\ 904 = 892\ 243$$

$$\Delta H_{P\ 1500} = 61\ 705 + 2 \times 48\ 149 + 2 \times 40\ 600 + 15.04 \times 38\ 405 = 816\ 814$$

$$\Delta H_{P\ 1400} = 55\ 895 + 2 \times 43\ 491 + 2 \times 36\ 958 + 15.04 \times 34\ 936 = 742\ 230$$

Linear interpolation to get 802 160

$$T = 1400 + 100\ \frac{802\ 160 - 742\ 230}{816\ 814 - 742\ 230} = \mathbf{1480\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.97

Solid carbon is burned with stoichiometric air in a steady flow process. The reactants at T_0, P_0 are heated in a preheater to T_2 = 500 K as shown in Fig. P13.97, with the energy given by the product gases before flowing to a second heat exchanger, which they leave at T_0. Find the temperature of the products T_4, and the heat transfer per kmol of fuel (4 to 5) in the second heat exchanger.

Combustion of carbon:

$$C + O_2 + 3.76\ N_2 \rightarrow CO_2 + 3.76\ N_2$$

C.V. Combustion chamber and preheater from 1 to 4, no external Q. For this CV states 2 and 3 are internal and do not appear in equations.

Energy Eq.:

$$H_R = H_R^\circ = H_{P_4} = H_P^\circ + \Delta H_{P_4} = \bar{h}_{f\,CO_2} + \Delta\bar{h}_{CO_2} + 3.76\Delta\bar{h}_{N_2}$$

Table A.9 or A.10: $\bar{h}_{f\,CO_2}$ = -393 522 kJ/kmol, reference $H_R^\circ = 0$

$$\Delta H_{P_4} = H_R^\circ - H_P^\circ = 0 - \bar{h}_{f\,CO_2} = 393\ 522 \text{ kJ/kmol fuel}$$

$$\Delta H_{P_4\,2400} = 115\ 779 + 3.76 \times 70\ 640 = 381\ 385 \text{ kJ/kmol fuel,}$$

$$\Delta H_{P_4\,2600} = 128\ 074 + 3.76 \times 77\ 963 = 421\ 215 \text{ kJ/kmol fuel}$$

interpolate $\Rightarrow$ $T_4 = T_{ad.flame} =$ **2461 K**

Control volume: Total. Then energy equation:

$$H_R^\circ + \bar{Q} = H_P^\circ$$

$$\bar{Q} = \bar{H}_{RP}^\circ = \bar{h}_{f\,CO_2}^\circ - 0 = \mathbf{-393\ 522\ \frac{kJ}{kmol\ fuel}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.98

Gaseous ethanol, C_2H_5OH, is burned with pure oxygen in a constant volume combustion bomb. The reactants are charged in a stoichiometric ratio at the reference condition. Assume no heat transfer and find the final temperature (> 5000 K).

$$C_2H_5OH + 3\ O_2 \rightarrow 2\ CO_2 + 3\ H_2O$$

Energy Eq.:

$$U_P = U_R = H_R^\circ + \Delta H_R - n_R\bar{R}T_R = H_P^\circ + \Delta H_P - n_P\bar{R}T_P$$

Solve for the properties that depends on T_P and recall $\Delta H_R = 0$

$$\Delta H_P - n_P\bar{R}T_P = H_R^\circ - H_P^\circ - n_R\bar{R}T_R = \bar{h}^0_{f\ fuel} - 2\ \bar{h}^0_{f\ CO2} - 3\ \bar{h}^0_{f\ H2O} - 4\bar{R}T_R$$

Fuel: $\bar{h}^0_{f\ fuel}$ = -235 000 kJ/kmol for IG from Table A.10 so

$$\Delta H_P - n_P\bar{R}T_P = -235\ 000 - 2(-393\ 522) - 3(-241\ 826)$$
$$- 4 \times 8.31451 \times 298.15 = 1\ 267\ 606\ \text{kJ/kmol}$$

$$\text{LHS} = \Delta H_P - n_P\bar{R}T_P = 2\ \Delta\bar{h}_{CO_2} + 3\ \Delta\bar{h}_{H_2O} - 5 \times 8.31451 \times T_P$$

From Table A.9 we find

$$\text{LHS}_{5600} = 2 \times 317\ 870 + 3 \times 278\ 161 - 41.5726 \times 5600 = 1\ 237\ 417$$

$$\text{LHS}_{6000} = 2 \times 343\ 782 + 3 \times 302\ 295 - 41.5726 \times 6000 = 1\ 345\ 014$$

$$T_{ad.flame} = \mathbf{5712\ K}$$

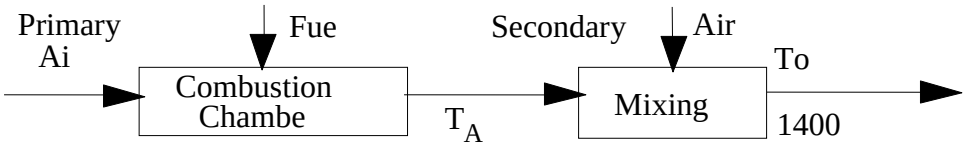
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.99

Liquid *n*-butane at T_0, is sprayed into a gas turbine with primary air flowing at 1.0 MPa, 400 K in a stoichiometric ratio. After complete combustion, the products are at the adiabatic flame temperature, which is too high, so secondary air at 1.0 MPa, 400 K is added, with the resulting mixture being at 1400 K. Show that $T_{ad} > 1400$ K and find the ratio of secondary to primary air flow.

C.V. Combustion Chamber.

$$C_4H_{10} + 6.5\ O_2 + 6.5 \times 3.76\ N_2 \rightarrow 5\ H_2O + 4\ CO_2 + 24.44\ N_2$$



Energy Eq.: $H_{air} + H_{fuel} = H_R = H_P$

$$\overset{\circ}{H}_P + \Delta H_P = \overset{\circ}{H}_R + \Delta H_R \quad \Rightarrow \quad \Delta H_P = \overset{\circ}{H}_R + \Delta H_R - \overset{\circ}{H}_P = -\overset{\circ}{H}_{RP} + \Delta H_R$$

$$\Delta H_P = 45344 \times 58.124 + 6.5(3.76 \times 2971 + 3027) = \mathbf{2\ 727\ 861\ kJ/kmol}$$

$$\Delta H_{P\ 1400} = 5 \times 43491 + 4 \times 55895 + 24.44 \times 34936 = \mathbf{1\ 294\ 871 < \Delta H_P}$$

Remark: Try $T_{AD} > 1400$:

$$\Delta H_P = 2\ 658\ 263\ @2400\ K, \quad \Delta H_P = 2\ 940\ 312\ @2600\ K$$

C.V. Mixing Chamber. Air Second: $\nu_{O2\ s} O_2 + 3.76\ N_2$

$$\Delta H_P + \nu_{O2\ second}\, \Delta H_{air} = \Delta H_{P\ 1400} + \nu_{O2\ second}\, \Delta H_{air\ 1400}$$

$$\Rightarrow \nu_{O2\ second} = \frac{\Delta H_P - \Delta H_{P\ 1400}}{\Delta H_{air\ 1400} - \Delta H_{air\ 400}} = \frac{1432990}{168317 - 14198} = \mathbf{9.3}$$

ratio = $\nu_{O2\ sec}/\nu_{O2\ prim} = 9.3/6.5 = \mathbf{1.43}$

13.100

The enthalpy of formation of magnesium oxide, MgO(s), is –601 827 kJ/kmol at 25°C. The melting point of magnesium oxide is approximately 3000 K, and the increase in enthalpy between 298 and 3000 K is 128 449 kJ/kmol. The enthalpy of sublimation at 3000 K is estimated at 418 000 kJ/kmol, and the specific heat of magnesium oxide vapor above 3000 K is estimated at 37.24 kJ/kmol K.

a. Determine the enthalpy of combustion per kilogram of magnesium.

b. Estimate the adiabatic flame temperature when magnesium is burned with theoretical oxygen.

a) $Mg + \frac{1}{2}O_2 \rightarrow MgO(s)$

$$\Delta h_{COMB} = \frac{\Delta \bar{h}_{COMB}}{M} = \frac{\bar{h}^\circ_f}{M} = \frac{-601\,827}{24.32} = \mathbf{-24\,746\ kJ/kg}$$

b) assume $T_R = 25°C$ and also that $T_P > 3000$ K, (MgO = vapor phase)

1st law: $Q_{CV} = H_P - H_R = 0$, but $H_R = 0$

$$\Rightarrow H_P = \bar{h}^\circ_f + (\bar{h}_{3000} - \bar{h}_{298})_{SOL} + \Delta \bar{h}_{SUB} + \bar{C}_{P\,VAP}(T_P - 3000)$$

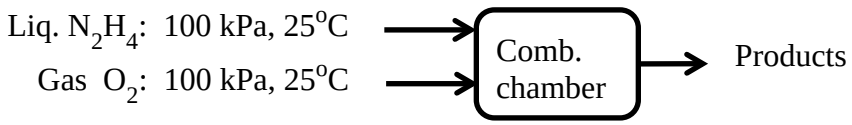
$$= -601\,827 + 128\,449 + 418\,000 + 37.24(T_P - 3000) = 0$$

Solving, $T_P = \mathbf{4487\ K}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.101

In a test of rocket propellant performance, liquid hydrazine (N_2H_4) at 100 kPa, 25°C, and oxygen gas at 100 kPa, 25°C, are fed to a combustion chamber in the ratio of 0.5 kg O_2/kg N_2H_4. The heat transfer from the chamber to the surroundings is estimated to be 100 kJ/kg N_2H_4. Determine the temperature of the products exiting the chamber. Assume that only H_2O, H_2, and N_2 are present. The enthalpy of formation of liquid hydrazine is +50 417 kJ/kmol.



$\dot{m}_{O2}/\dot{m}_{N2H4} = 0.5 = 32\dot{n}_{O2}/32\dot{n}_{N2H4}$ and $\dot{Q}/\dot{m}_{N2H4} = -100$ kJ/kg

Energy Eq.: $Q_{CV} = H_P - H_R = -100 \times 32.045 = -3205$ kJ/kmol fuel

Combustion eq.: $1\, N_2H_4 + \frac{1}{2} O_2 \rightarrow H_2O + H_2 + N_2$

$H_R = 1(50417) + \frac{1}{2}(0) = 50417$ kJ

$H_P = -241\,826 + \Delta\bar{h}_{H2O} + \Delta\bar{h}_{H2} + \Delta\bar{h}_{N2}$

Energy Eq. now reads

$$H_P = H_R + Q_{CV} = H_P^o + \Delta H_P$$

$$\Delta H_P = \Delta\bar{h}_{H2O} + \Delta\bar{h}_{H2} + \Delta\bar{h}_{N2} = -H_P^o + H_R + Q_{CV}$$
$$= 241\,826 + 50\,417 - 3205 = 289\,038 \text{ kJ/kmol fuel}$$

Table A.9 : Guess T and read for water, hydrogen and nitrogen

2800 K: $\Delta H_P = 115\,463 + 81\,355 + 85\,323 = 282\,141$ too low

3000 K: $\Delta H_P = 126\,548 + 88\,725 + 92\,715 = 307\,988$ too high

Interpolate to get $T_P =$ **2854 K**

Second Law for the Combustion Process

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.102

Consider the combustion of hydrogen with pure oxygen in a stoichiometric ratio under steady flow adiabatic conditions. The reactants enter separately at 298 K, 100 kPa and the product(s) exit at a pressure of 100 kPa. What is the exit temperature and what is the irreversibility?

The reaction equation is:

$$H_2 + \nu_{O2}\, O_2 \quad => \quad H_2O$$

The balance of hydrogen is done, now for oxygen we need $\nu_{O2} = 0.5$.

Energy Eq.: $H_R = H_P \;=>\; 0 = -241\,826 + \Delta\bar{h}_{H2O}$

$$=> \quad \Delta\bar{h}_{H2O} = 241\,826 \text{ kJ/kmol}$$

Interpolate now in table A.9 for the temperature to give this enthalpy

T = 4991 K

For this temperature we find from Table A.9, in this case $P = P_o$, so we do not need any pressure correction for the entropy

$$S_P = S_P^\circ = \bar{s}_{H2O}^\circ = 315.848 \text{ kJ/kmol K}$$

For the reactants we have (again no pressure correction)

$$S_R = \bar{s}_{H2}^\circ + 0.5\, \bar{s}_{O2}^\circ = 130.678 + 0.5 \times 205.148 = 233.252 \text{ kJ/kmol K}$$

$$S_{gen} = S_P - S_R = 315.848 - 233.252 = 82.596 \text{ kJ/kmol } H_2 \text{ K}$$

$$I = T_o\, S_{gen} = 298.15 \times 82.596 = \mathbf{24\,626 \text{ kJ/kmol } H_2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.103

Consider the combustion of methanol, CH_3OH, with 25% excess air. The combustion products are passed through a heat exchanger and exit at 200 kPa, 400 K. Calculate the absolute entropy of the products exiting the heat exchanger assuming all the water is vapor.

$$CH_3OH + 1.25 \times 1.5\,(O_2 + 3.76\,N_2) \rightarrow CO_2 + 2\,H_2O + 0.375\,O_2 + 7.05\,N_2$$

We need to find the mole fractions to do the partial pressures,

$$n = 1 + 2 + 0.375 + 7.05 = 10.425 \quad => \quad y_i = n_i / n$$

Gas mixture:

	n_i	y_i	$\bar{s}_i^\circ$	$-\bar{R}\ln \frac{y_i P}{P_0}$	$\bar{S}_i$
CO_2	1.0	0.0959	225.314	+13.730	239.044
H_2O	2	0.1918	198.787	+7.967	206.754
O_2	0.375	0.0360	213.873	+20.876	234.749
N_2	7.05	0.6763	200.181	-2.511	197.670

$$S_{GAS\ MIX} = \sum n_i \bar{S}_i = \textbf{2134.5 kJ/K kmol fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.104

Consider the combustion of methanol, CH_3OH, with 25% excess air. The combustion products are passed through a heat exchanger and exit at 200 kPa, 40°C. Calculate the absolute entropy of the products exiting the heat exchanger per kilomole of methanol burned, using the proper amounts of liquid and vapor for the water.

$$CH_3OH + 1.25 \times 1.5\,(O_2 + 3.76\,N_2) \rightarrow CO_2 + 2\,H_2O + 0.375\,O_2 + 7.05\,N_2$$

Products exit at 40 ^{o}C, 200 kPa, check for saturation:

$$y_{V\,MAX} = \frac{P_G}{P} = \frac{7.384}{200} = \frac{n_{V\,MAX}}{n_{V\,MAX} + 1 + 0.375 + 7.05}$$

$$n_V = n_{V\,MAX} = 0.323 \quad n_{LIQ} = 1.677$$

Gas mixture:

	n_i	y_i	$\bar{s}_i^{\circ}$	$-\bar{R}\ln\frac{y_i P}{P_0}$	$\bar{S}_i$
CO_2	1.0	0.1143	215.633	+12.270	227.903
H_2O	0.323	0.0369	190.485	+21.671	212.156
O_2	0.375	0.0429	206.592	+20.418	227.01
N_2	7.05	0.8059	193.039	-3.969	189.07

$$S_{GAS\,MIX} = \sum n_i \bar{S}_i = 1714.50 \text{ kJ/K kmol fuel}$$

$$\bar{s}_{LIQ} = 69.950 + 18.015(0.5725 - 0.3674) = 73.645 \text{ kJ/kmol}$$

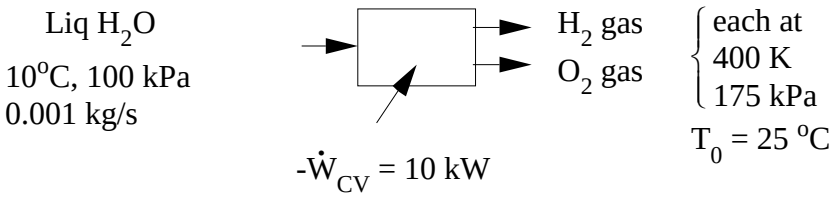
$$S_{LIQ} = 1.677 \times 73.645 = 123.50 \text{ kJ/K kmol fuel}$$

$$S_{PROD} = 1714.50 + 123.50 = \mathbf{1838\ kJ/K\ kmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.105

An inventor claims to have built a device that will take 0.001 kg/s of water from the faucet at 10°C, 100 kPa, and produce separate streams of hydrogen and oxygen gas, each at 400 K, 175 kPa. It is stated that this device operates in a 25°C room on 10-kW electrical power input. How do you evaluate this claim?



$$H_2O \rightarrow H_2 + \tfrac{1}{2}O_2$$

$$H_i - H_e = [-285830 + 18.015(42.01 - 104.89)] - 2961 - \tfrac{1}{2}(3027)$$

$$= -291\,437 \text{ kJ/kmol}$$

$$(S_i - S_e) = [69.950 + 18.015(0.151 - 0.3674)] - (139.219 - 8.3145 \ln 1.75)$$

$$- \tfrac{1}{2}(213.873 - 8.3145 \ln 1.75) = -173.124 \text{ kJ/kmol K}$$

$$W_{REV} = (H_i - H_e) - T_0(S_i - S_e) = -291\,437 - 298.15(-173.124)$$

$$= -239820 \text{ kJ/kmol}$$

$$\dot{W}_{REV} = (0.001/18.015)(-239\,820) = -13.31 \text{ kW}$$

$$\dot{I} = \dot{W}_{REV} - \dot{W}_{CV} = -13.31 - (-10) < 0 \qquad \textbf{Impossible}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.106

Propene, C_3H_6, is burned with air in a steady flow burner with reactants at P_o, T_o. The mixture is lean so the adiabatic flame temperature is 1800 K. Find the entropy generation per kmol fuel neglecting all the partial pressure corrections.

The reaction equation for a mixture with excess air is:

$$C_3H_6 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 3\,H_2O + 3\,CO_2 + 3.76\nu_{O2}\,N_2 + (\nu_{O2} - 4.5)O_2$$

Energy Eq.: $$H_R = H_R^\circ + \Delta H_R = H_R^\circ = H_P = H_P^\circ + \Delta H_P$$

The entropy equation: $$S_R + S_{gen} = S_P \quad => \quad S_{gen} = S_P - S_R = S_P - S_R^\circ$$

From table A.9 at reference T

$$\Delta H_R = \Delta h_{Fu} + \nu_{O2}(\Delta h_{O2} + 3.76\,\Delta h_{N2}) = 0$$

From table A.9 at 1800 K:

$$\Delta H_P = 3\,\Delta h_{H2O} + 3\,\Delta h_{CO2} + 3.76\,\nu_{O2}\,\Delta h_{N2} + (\nu_{O2} - 4.5)\,\Delta h_{O2}$$

$$= 3 \times 62\,693 + 3 \times 79432 + 3.76\,\nu_{O2} \times 48\,979 + (\nu_{O2} - 4.5)\,51\,674$$

$$= 193\,842 + 235\,835\,\nu_{O2}$$

From table 13.3: $H_P^\circ - H_R^\circ = H_{RP}^\circ = 42.081(-45\,780) = -1\,926\,468$ kJ/kmol

Now substitute all terms into the energy equation

$$-1\,926\,468 + 193\,842 + 235\,835\,\nu_{O2} = 0$$

Solve for ν_{O2}: $$\nu_{O2} = \frac{1\,926\,468 - 193\,842}{235\,835} = 7.3468, \quad \nu_{N2} = 27.624$$

Table A.9-10 contains the entropies at 100 kPa so we get:

$$S_P = 3 \times 259.452 + 3 \times 302.969 + (7.3468 - 4.5)\,264.797 + 27.624 \times 248.304$$

$$= 9300.24 \text{ kJ/kmol-K}$$

$$S_R = 267.066 + 7.3468 \times 205.148 + 27.624 \times 191.609 = 7067.25 \text{ kJ/kmol K}$$

$$S_{gen} = 9300.24 - 7067.25 = \mathbf{2233\ kJ/kmol\text{-}K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.107

Hydrogen peroxide, H_2O_2, enters a gas generator at 25°C, 500 kPa at the rate of 0.1 kg/s and is decomposed to steam and oxygen exiting at 800 K, 500 kPa. The resulting mixture is expanded through a turbine to atmospheric pressure, 100 kPa, as shown in Fig. P13.107. Determine the power output of the turbine, and the heat transfer rate in the gas generator. The enthalpy of formation of liquid H_2O_2 is −187 583 kJ/kmol.

$$H_2O_2 \rightarrow H_2O + \frac{1}{2} O_2 \qquad \dot{n}_{H2O2} = \frac{\dot{m}_{H2O2}}{M} = \frac{0.1}{34.015} = 0.00294 \text{ kmol/s}$$

$$\dot{n}_{ex,mix} = \dot{n}_{H2O2} \times 1.5 = 0.00441 \text{ kmol/s}$$

$$\bar{C}_{p\,mix} = \frac{2}{3} \times 1.872 \times 18.015 + \frac{1}{3} \times 0.922 \times 31.999 = 32.317$$

$$\bar{C}_{v\,mix} = 32.317 - 8.3145 = 24.0 \quad => \quad k_{mix} = 32.317/24.0 = 1.3464$$

CV: turbine. Assume reversible $\rightarrow s_3 = s_2$

$$T_3 = T_2 \left(\frac{P_3}{P_2}\right)^{\frac{k-1}{k}} = 800 \left(\frac{100}{500}\right)^{0.2573} = 528.8 \text{ K}$$

$$w = \bar{C}_{p\,mix} (T_2 - T_3) = 32.317(800 - 528.8) = 8765 \text{ kJ/kmol}$$

$$\dot{W}_{CV} = \dot{n}_{ex,mix}\, w = 0.00441 \times 8765 = \mathbf{38.66\ kW}$$

CV: Gas Generator

$$\dot{H}_1 = 0.00294(-187\,583 + 0) = -551.49$$

$$\dot{H}_2 = 0.00294(-241\,826 + 18002) + 0.00147(0 + 15836) = -634.76$$

$$\dot{Q}_{CV} = \dot{H}_2 - \dot{H}_1 = -634.76 + 551.49 = \mathbf{-83.27\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.108

Graphite, C, at P_0, T_0 is burned with air coming in at P_0, 500 K in a ratio so the products exit at P_0, 1200 K. Find the equivalence ratio, the percent theoretical air, and the total irreversibility.

$$C + (1/\phi)b(O_2 + 3.76\ N_2) \rightarrow CO_2 + ((1/\phi) - 1)O_2 + 3.76\ (1/\phi)\ N_2$$

Stoichiometric: b = 1

Energy Eq.: $H_P = H_R \Rightarrow \Delta H_{P\ 1200} - \Delta H_R = H_R^\circ - H_P^\circ$

$$44\ 473 + ((1/\phi) - 1)29\ 761 + 3.76(1/\phi)28\ 109$$
$$- (1/\phi)(6086 + 3.76 \times 5911) = 0 - (-393\ 522) \Rightarrow (1/\phi) = 3.536$$

$$S_{gen} = S_P - S_R = \sum_{P-R} \nu\left(\bar{s}^\circ - \bar{R}\ln(y)\right)$$

Reactants: $y_{O_2} = 0.21$, $y_{N_2} = 0.79$ (carbon is solid)

Products: $y_{O_2} = 0.1507$, $y_{N_2} = 0.79$, $y_{CO_2} = 0.0593$

$S_P^\circ = 279.39 + 2.536 \times 250.011 + 13.295 \times 234.227 = 4027.5$

$S_R^\circ = 5.74 + 3.536(220.693 + 3.76 \times 206.74) = 3534.8$

For the pressure correction the term with the nitrogen drops out (same y).

$$\bar{R} \sum_{P-R} -\nu \ln(y) = \bar{R}\ [-\ln(y_{CO_2}) - 2.536 \ln(y_{O_2\ prod}) + 3.536 \ln(y_{O_2\ reac})]$$
$$= \bar{R}\ [\ -\ln(0.0593) - 2.536 \ln(0.1507) + 3.536 \ln(0.21)\ ]$$
$$= 8.3145(2.8235 + 2.536 \times 1.8927 - 3.536 \times 1.5606) = 17.503$$

$S_{gen} = 4027.5 - 3534.8 + 17.503 = 510.2$ kJ/kmol carbon-K

$I = T_0\ S_{gen} = \mathbf{152\ 117}\ \frac{\mathbf{kJ}}{\mathbf{kmol\ C}}$

13.110

Two kilomoles of ammonia are burned in a steady flow process with *x* kmol of oxygen. The products, consisting of H_2O, N_2, and the excess O_2, exit at 200°C, 7 MPa.

a. Calculate *x* if half the water in the products is condensed.

b. Calculate the absolute entropy of the products at the exit conditions.

$$2NH_3 + xO_2 \rightarrow 3H_2O + N_2 + (x - 1.5)O_2$$

Products at 200 °C, 7 MPa with $n_{H2O\ LIQ} = n_{H2O\ VAP} = 1.5$

a) $y_{H2O\ VAP} = P_G/P = \dfrac{1.5538}{7} = \dfrac{1.5}{1.5 + 1 + x - 1.5}$ => x = **5.757**

b) $S_{PROD} = S_{GAS\ MIX} + S_{H2O\ LIQ}$

Gas mixture:	n_i	y_i	$\bar{s}_i^\circ$	$-\bar{R}\ln(y_iP/P_0)$	S_i
H_2O	1.5	0.222	204.595	-22.810	181.785
O_2	4.257	0.630	218.985	-31.482	187.503
N_2	1.0	0.148	205.110	-19.439	185.671

$S_{GAS\ MIX} = 1.5(181.785) + 4.257(187.503) + 1.0(185.67) = 1256.55$ kJ/K

$S_{H2O\ LIQ} = 1.5[69.950 + 18.015(2.3223 - 0.3674)] = 157.75$ kJ/K

$S_{PROD} = 1256.55 + 157.75 =$ **1414.3 kJ/K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.111

A flow of 0.02 kmol/s methane CH_4 and 200% theoretical air both at reference conditions are compressed separately to $P_3 = P_4 = 2$ MPa, then mixed and then burned in a steady flow setup (like a gasturbine). After combustion, state 6, heat transfer goes out so the exhaust, state 7, is at 600 K.

a) Find T_3, T_4 and T_5

b) Find the total rate of irreversibility from inlet to state 5.

c) Find the rate of heat transfer minus the work terms $(\dot{Q} - \dot{W}_1 - \dot{W}_2)$

The reaction equation for stoichiometric ratio is:

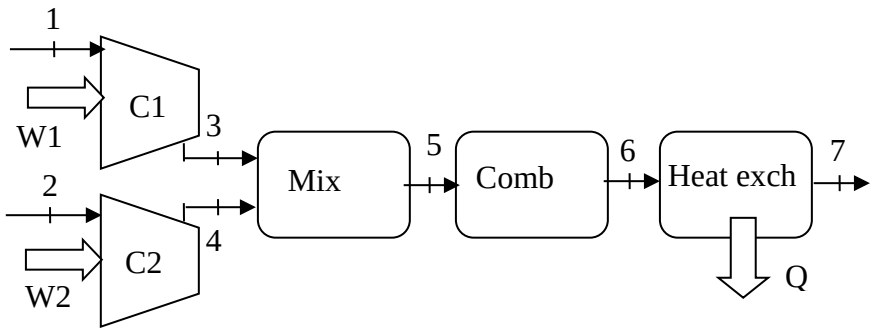
$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \Rightarrow CO_2 + 2\,H_2O + \nu_{O2} \times 3.76\,N_2$$

where the carbon and hydrogen balance have been done. Now the oxygen

$$O: \quad 2\nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2; \quad \nu_{N2} = 7.52$$

The actual combustion becomes $\nu_{O2} = 2 \times 2 = 4$; $\nu_{N2} = 15.04$

$$CH_4 + 4\,(O_2 + 3.76\,N_2) \Rightarrow CO_2 + 2\,H_2O + 15.04\,N_2 + 2\,O_2$$



The two compressors assumed adiabatic and reversible

Air: $$T_3 = T_1 \left(P_3/P_1\right)^{\frac{k-1}{k}} = 298.15\,(2000/100)^{\frac{1.4-1}{1.4}} = \mathbf{701.7\ K}$$

CH_4: $$T_4 = T_2 \left(P_4/P_2\right)^{\frac{k-1}{k}} = 298.15\,(2000/100)^{\frac{1.299-1}{1.299}} = \mathbf{594.2\ K}$$

$$\dot{n}_{air} = 4 \times 4.76\ \dot{n}_{Fu} = 19.04\ \dot{n}_{Fu} = 0.3808 \text{ kmol/s}$$

$$\bar{C}_{Pair} = 28.97 \times 1.004 = 29.0859 \text{ kJ/kmol-K},$$

$$\bar{C}_{PFu} = 16.043 \times 2.254 = 36.1609 \text{ kJ/kmol-K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Energy Eq. mixing chamber :

$$\dot{n}_{air}\,\bar{h}_3 + \dot{n}_{Fu}\,\bar{h}_4 = \dot{n}_{air}\,\bar{h}_{5\,air} + \dot{n}_{Fu}\,\bar{h}_{5\,Fu}$$

use constant specific heats to evaluate and divide with $\dot{n}_{Fu}$ to get

$$19.04 \times 29.0859 \times 701.7 + 36.1609 \times 594.2 = (19.04 \times 29.0859 + 36.1609)\,T_5$$

solve $T_5 =$ **695.1 K**

C.V. From the inlet 1,2 to the exit state 5, no $\dot{Q}$ so $y_{5\,air} = \dfrac{19.04}{20.04}$, $y_{5\,Fu} = \dfrac{1}{20.04}$

$$\dot{S}_{gen} = \dot{n}_{air}(\bar{s}_{5\,air} - \bar{s}_1) + \dot{n}_{Fu}\,(\bar{s}_{5\,Fu} - \bar{s}_2)$$

$$= 0.3808\,[29.0859 \ln(\frac{695.1}{298.15}) - 8.3145 \ln(\frac{19.04}{20.04}\frac{2000}{100})]$$

$$+ 0.02\,[36.1609 \ln(\frac{695.1}{298.15}) - 8.3145 \ln(\frac{1}{20.04}\frac{2000}{100})\,]$$

$$= 0.3808 \times 0.1376 + 0.02 \times 30.625 = 0.6649 \text{ kW/K}$$

$$\dot{I} = T_o\,\dot{S}_{gen} = 298.15 \times 0.6649 = \textbf{198.2 kW}$$

C.V. Total control volume from inlet 1, 2 to final exit at state 7

$$\dot{Q} - \dot{W}_1 - \dot{W}_2 = \dot{n}_{air}\,\bar{h}_1 + \dot{n}_{Fu}\,\bar{h}_2 - \dot{n}_P\,\bar{h}_7 = \dot{n}_{Fu}\,[H_R - H_P]$$

$$H_R - H_P = H_R^o - H_P^o - \Delta H_P = -\overset{\circ}{H}_{RP} - \Delta H_P$$

The lower heating value per kmol fuel is

$$LHV = -\overset{\circ}{H}_{RP} = H_R^o - H_P^o = 16.043 \times 50\,010 = 802\,310.4 \text{ kJ/kmol}$$

$$\Delta H_P = \Delta\bar{h}_{CO_2} + 2\,\Delta\bar{h}_{H_2O} + 15.04\,\Delta\bar{h}_{N_2} + 2\,\Delta\bar{h}_{O_2}$$

$$= 12\,906 + 2 \times 10\,499 + 15.04 \times 8894 + 2 \times 9245$$

$$= 186\,159.8 \text{ kJ/kmol fuel}$$

$$\dot{Q} - \dot{W}_1 - \dot{W}_2 = 0.02 \times (802\,310.4 - 186\,159.8) = 12\,323 \text{ kW} = \textbf{12.3 MW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.112

A flow of hydrogen gas is mixed with a flow of oxygen in a stoichiometric ratio, both at 298 K and 50 kPa. The mixture burns without any heat transfer in complete combustion. Find the adiabatic flame temperature and the amount of entropy generated per kmole hydrogen in the process.

The reaction equation is:

$$H_2 + \nu_{O2}\, O_2 \quad => \quad H_2O$$

The balance of hydrogen is done, now for oxygen we need $\nu_{O2} = 0.5$.

Energy Eq.: $H_R = H_P \;=>\; 0 = -241\,826 + \Delta\bar{h}_{H2O}$

$$=> \quad \Delta\bar{h}_{H2O} = 241\,826 \text{ kJ/kmol}$$

Interpolate now in table A.9 for the temperature to give this enthalpy

T = 4991 K

For this temperature we find from Table A.9

$$S_p = \bar{s}^{\circ}_{H2O} - \bar{R}\ln(P/P_o) = 315.848 - 8.31451 \ln(0.5) = 321.611 \text{ kJ/kmol K}$$

For the reactants we have

$$S_R = \bar{s}^{\circ}_{H2} - \bar{R}\ln(P/P_o) + 0.5\,[\bar{s}^{\circ}_{O2} - \bar{R}\ln(P/P_o)]$$

$$= 130.678 + 0.5 \times 205.148 - 1.5 \times 8.31451 \ln(0.5)$$

$$= 241.897 \text{ kJ/kmol K}$$

$$S_{gen} = S_P - S_R = 321.611 - 241.897 = \mathbf{79.714\ kJ/kmol\ H_2\ K}$$

Recall that this entropy generation includes the mixing process, we did not use the partial pressures after mixing but the total pressure (50 kPa) before mixing.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.113

Methane is burned with air, both of which are supplied at the reference conditions. There is enough excess air to give a flame temperature of 1800 K. What are the percent theoretical air and the irreversibility in the process?

The combustion equation with X times theoretical air is

$$CH_4 + 2X(O_2 + 3.76\ N_2) \rightarrow CO_2 + 2H_2O + 2(X\text{-}1)O_2 + 7.52X\ N_2$$

Energy Eq.: $H_{air} + H_{fuel} = H_R = H_P = H_P^\circ + \Delta H_P = H_R^\circ + \Delta H_R$

$$\Rightarrow \quad \Delta H_P = H_R^\circ + \Delta H_R - H_P^\circ = -H_{RP}^\circ + 0$$

From Table 13.3: $-H_{RP}^\circ = -16.04\ (-50\ 010) = 802\ 160$ kJ/kmol

$$\Delta H_P = \Delta \bar{h}^*_{CO2} + 2\ \Delta \bar{h}^*_{H2O} + 2(X\text{-}1)\ \Delta \bar{h}^*_{O2} + 7.52X\ \Delta \bar{h}^*_{N2}$$

From Table A.9 and the energy equation

$$\Delta H_{P\ 1800} = 79\ 432 + 2 \times 62\ 693 + 2(X\text{-}1)\ 51\ 674 + 7.52X \times 48\ 979 = 802\ 160$$

so

$$101\ 470 + 471\ 670\ X = 802\ 160 \quad \Rightarrow \quad X = 1.4856$$

%Theoretical air = **148.6%**

The products are

Products: $CO_2 + 2H_2O + 0.9712\ O_2 + 11.172\ N_2$

The second law

$$S_{gen} = S_P - S_R \quad \text{and} \quad I = T_o\ S_{gen}$$

Reactants: $P_i = 100$ kPa, $P_o = 100$ kPa, $\bar{s}^o_f$ from Table A.9

	n_i	y_i	$\bar{s}^o_f$	$-\bar{R} \ln \frac{y_i P_i}{P_o}$	$\bar{S}_i$ $\frac{\text{kJ}}{\text{kmol K}}$

13.114

Pentane gas at 25°C, 150 kPa enters an insulated steady flow combustion chamber. Sufficient excess air to hold the combustion products temperature to 1800 K enters separately at 500 K, 150 kPa. Calculate the percent theoretical air required and the irreversibility of the process per kmol of pentane burned.

$$C_5H_{12} + 8X(O_2 + 3.76\, N_2) \rightarrow 5\, CO_2 + 6\, H_2O + 8(X-1)\, O_2 + 30.08X\, N_2$$

Energy Eq.: $Q_{CV} + H_R = H_P + W_{CV}$; $W_{CV} = 0$, $Q_{CV} = 0$

Reactants: C_5H_{12} : $\bar{h}_f^o$ from A.9 and $\Delta\bar{h}_{500}$ for O_2 and N_2 from A.9

$$H_R = (\bar{h}_f^o)_{C5H12} + 8X\, \Delta\bar{h}_{O2} + 30.08X\, \Delta\bar{h}_{N2}$$
$$= -146\,500 + 8X\ 6086 + 30.08\ X\ 5911 = 226\,491\ X - 146\,500$$

$$H_P = 5(\bar{h}_f^o + \Delta\bar{h})_{CO2} + 6(\bar{h}_f^o + \Delta\bar{h})_{H2O} + 8(X-1)\, \Delta\bar{h}_{O2} + 30.08\ X\ \Delta\bar{h}_{N2}$$
$$= 5(-393\,522 + 79\,432) + 6(-241\,826 + 62\,693) + 8(X-1)\ 51\,674$$
$$+ 30.08\ X\ 48\,979 = 1\,886\,680\ X - 3\,058\,640$$

Energy Eq. solve for X;

$$H_R = H_P = 226\,491\ X - 146\,500 = 1\,886\,680\ X - 3\,058\,640$$

$$\Rightarrow \quad X = \mathbf{1.754}$$

13.115

A closed rigid container is charged with propene, C_3H_6, and 150% theoretical air at 100 kPa, 298 K. The mixture is ignited and burns with complete combustion. Heat is transferred to a reservoir at 500 K so the final temperature of the products is 700 K. Find the final pressure, the heat transfer per kmole fuel and the total entropy generated per kmol fuel in the process.

$$C_3H_6 + \nu_{O_2}(O_2 + 3.76\, N_2) \rightarrow 3\, CO_2 + 3\, H_2O + x\, N_2$$

Oxygen, O_2 , balance: $\quad 2\,\nu_{O_2} = 6 + 3 = 9 \quad \Rightarrow \quad \nu_{O_2} = 4.5$

Actual Combustion: $\quad \phi = 1.5 \;\Rightarrow\; \nu_{O_2\,ac} = 1.5 \times 4.5 = 6.75$

$$C_3H_6 + 6.75\, O_2 + 25.38\, N_2 \;\rightarrow\; 3\, CO_2 + 3\, H_2O + 25.38\, N_2 + 2.25\, O_2$$

$$P_2 = P_1 \frac{n_p T_2}{n_R T_1} = 100 \times \frac{33.63 \times 700}{33.13 \times 298.15} = \mathbf{238.3\ kPa}$$

Enthalpies from Table A.9

$$\Delta H_{P\,700} = 3{\times}17\,754 + 3{\times}14\,190 + 25.38{\times}11\,937 + 2.25{\times}12\,499$$

$$= 426\,916 \ \frac{\text{kJ}}{\text{kmol fuel}}$$

Enthalpy of combustion from table 13.3 converted to mole basis

$$\overset{\circ}{H}_{RP} = -45\,780 \times 42.081 = -1\,926\,468 \text{ kJ/kmol fuel}$$

$$U_2 - U_1 = {}_1Q_2 - 0 = H_2 - H_1 - n_2\bar{R}\bar{T}_2 + n_1\bar{R}\bar{T}_1$$

$${}_1Q_2 = \overset{\circ}{H}_{RP} + \Delta H_{P\,700} - n_P\bar{R}\bar{T}_2 + n_1\bar{R}\bar{T}_1$$

$$= -1\,926\,468 + 426\,916 - 33.63 \times 8.3145 \times 700$$

13.117

Repeat Problem 13.101, but assume that saturated-liquid oxygen at 90 K is used instead of 25°C oxygen gas in the combustion process. Use the generalized charts to determine the properties of liquid oxygen.

Problem same as 13.101, except oxygen enters at 2 as saturated liquid at 90 K.

$$\dot{m}_{O2}/\dot{m}_{N2H4} = 0.5 = 32\dot{n}_{O2}/32\dot{n}_{N2H4} \quad \text{and} \quad \dot{Q}/\dot{m}_{N2H4} = -100 \text{ kJ/kg}$$

Energy Eq.: $Q_{CV} = H_P - H_R = -100 \times 32.045 = -3205$ kJ/kmol fuel

Reaction equation: $1\, N_2H_4 + \frac{1}{2} O_2 \rightarrow H_2O + H_2 + N_2$

At 90 K, $T_{r2} = 90/154.6 = 0.582 \quad \Rightarrow \quad \Delta\tilde{h}_f = 5.2$

Figure D.2, $(\bar{h}^* - \bar{h}) = 8.3145 \times 154.6 \times 5.2 = 6684$ kJ/kmol

$\Delta\bar{h}_{AT\ 2} = -6684 + 0.922 \times 32 \times (90 - 298.15) = -12825$ kJ/kmol

$H_R = 50417 + \frac{1}{2}(0 - 12825) = 44005$ kJ, $\quad H_P^\circ = -241826$

Energy Eq: $\Delta\bar{h}_P = \Delta\bar{h}_{H_2O} + \Delta\bar{h}_{H_2} + \Delta\bar{h}_{N_2} = Q_{cv} + H_R - H_P^\circ = 282\,626$ kJ/kmol

From Table A.9, $\Delta H_{P\ 2800K} = 282\,141$, $\Delta H_{P\ 3000K} = 307\,988$ kJ/kmol

Therefore, $T_P =$ **2804 K**

13.118

A gas mixture of 50% ethane and 50% propane by volume enters a combustion chamber at 350 K, 10 MPa. Determine the enthalpy per kilomole of this mixture relative to the thermochemical base of enthalpy using Kay's rule.

$$\bar{h}^*_{MIX\ O} = 0.5(-84740) + 0.5(-103900) = -94320 \text{ kJ/kmol}$$

$$\bar{C}_{P0\ MIX} = 0.5 \times 30.07 \times 1.7662 + 0.5 \times 44.097 \times 1.67 = 63.583$$

$$\bar{h}^*_{350} - \bar{h}^*_{298} = 63.583 \times (350 - 298.2) = 3294 \text{ kJ/kmol}$$

Kay's rule: $T_{C\ MIX} = 0.5 \times 305.4 + 0.5 \times 369.8 = 337.6$ K

$$P_{C\ MIX} = 0.5 \times 4.88 + 0.5 \times 4.25 = 4.565 \text{ MPa}$$

$$T_r = 350/337.6 = 1.037, \quad P_r = 10/4.565 = 2.19$$

From Fig. D.2: $\bar{h}^* - \bar{h} = 8.3145 \times 337.6 \times 3.53 = 9909$ kJ/kmol

$$\bar{h}_{MIX\ 350K,10MPa} = -94320 + 3294 - 9909 = \mathbf{-100\ 935\ kJ/kmol}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.119

A mixture of 80% ethane and 20% methane on a mole basis is throttled from 10 MPa, 65°C, to 100 kPa and is fed to a combustion chamber where it undergoes complete combustion with air, which enters at 100 kPa, 600 K. The amount of air is such that the products of combustion exit at 100 kPa, 1200 K. Assume that the combustion process is adiabatic and that all components behave as ideal gases except the fuel mixture, which behaves according to the generalized charts, with Kay's rule for the pseudocritical constants. Determine the percentage of theoretical air used in the process and the dew-point temperature of the products.

Reaction equation:

Fuel mix: $\bar{h}^0_{f\,FUEL} = 0.2(-74873) + 0.8(-84740) = -82767$ kJ/kmol

$\bar{C}_{P0\,FUEL} = 0.2 \times 2.2537 \times 16.04 + 0.8 \times 1.7662 \times 30.07 = 49.718$

$\Delta\bar{h}^*_{FUEL} = 49.718(65 - 25) = 1989$ kJ/kmol

$T_{CA} = 305.4$ K, $T_{CB} = 190.4$ K $\Rightarrow$ $T_{c\,mix} = 282.4$ K

$P_{CA} = 4.88$, $P_{CB} = 4.60$ $\Rightarrow$ $P_{c\,mix} = 4.824$ MPa

$T_r = 338.2/282.4 = 1.198$, $P_r = 10/4.824 = 2.073$

$(\bar{h}^* - \bar{h})_{FUEL\,IN} = 8.31451 \times 282.4 \times 2.18 = 5119$

$\Rightarrow \bar{h}_{FUEL\,IN} = -82767 + 1989 - 5119 = -85897 \frac{kJ}{kmol}$

Energy Eq.:

$$1.8(-393522 + 44473) + 2.8(-241826 + 34506) + 3.2(x - 1)(29761) + (12.03x)(28109) + 85897 - (3.2x)(9245) - (12.03x)(8894) = 0$$

a) $x = 4.104$ or **410.4 %**

b) $n_p = 1.8 + 2.8 + 3.2(4.104 - 1) + 12.03 \times 4.104 = 63.904$

$y_{H2O} = 2.8/63.904 = P_V/100$; $P_V = 4.38$ kPa, $T =$ **30.5°C**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.120

Saturated liquid butane enters an insulated constant pressure combustion chamber at 25°C, and *x* times theoretical oxygen gas enters at the same *P* and *T*. The combustion products exit at 3400 K. With complete combustion find *x*. What is the pressure at the chamber exit? and what is the irreversibility of the process?

Butane: $T_1 = T_o = 25^oC$, sat liq., $x_1 = 0$, $T_c = 425.2$ K, $P_c = 3.8$ MPa

Do the properties from the generalized charts

Fig. D.1: $T_{r1} = 0.7$, $P_{r1} = 0.1$, $P_1 = P_{r1}P_c = 380$ kPa

Figs. D.2 and D.3: $\left(\bar{h}_1^* - \bar{h}_1\right)_f = 4.85\ \bar{R}T_c$, $(\bar{s}_1^* - \bar{s}_1)_f = 6.8\ \bar{R}$

Oxygen: $T_2 = T_o = 25^oC$, X - Theoretical O_2

Products: $T_3 = 3400$ K, Assumes complete combustion

$$C_4H_{10} + 6.5X\ O_2 \rightarrow 4\ CO_2 + 5\ H_2O + 6.5(X\text{-}1)\ O_2$$

Energy Eq.: $Q_{cv} + H_R = H_P + W_{cv}$; $Q_{cv} = 0$, $W_{cv} = 0$

$$H_R = n\left(\bar{h}_f^o + \Delta\bar{h}\right)_{C4H10} = 1(-126\ 200 + -17\ 146) = -143\ 346 \text{ kJ}$$

Products: CO_2 $n\left(\bar{h}_f^o + \Delta\bar{h}\right)_{CO2} = 4(-393\ 522 + 177\ 836) = -862\ 744$ kJ

H_2O $n\left(\bar{h}_f^o + \Delta\bar{h}\right)_{H2O} = 5(-241\ 826 + 149\ 073) = -463\ 765$ kJ

O_2 $n\left(\bar{h}_f^o + \Delta\bar{h}\right)_{O2} = 6.5(X\text{-}1)(0 + 114\ 101) = (X\text{-}1)741\ 657$ kJ

$$H_P = \sum n_i \left(\bar{h}_f^o + \Delta\bar{h}\right)_i = 741\ 657X - 2\ 068\ 166$$

Energy Eq.: $H_P = H_R$ solve for X; **X = 2.594**

Assume that the exit pressure equals the inlet pressure: $P_e = P_i = 380$ kPa

$$\bar{s}_{C_4H_{10}} = \left[\bar{s}_f^o - \bar{R}\ln\frac{P_1}{P_o} - (\bar{s}_1^* - \bar{s}_1)_f\right] \quad ; \quad \bar{s}_{O_2} = \left[\bar{s}^o - \bar{R}\ln\frac{P_1}{P_o}\right]$$

$$S_R = S_{C4H10} + S_{O2} = [306.647 - 11.10 - 56.539]$$
$$+ [205.48 - 11.10] \times 6.5 \times 2.594 = 3516.45 \text{ kJ/K}$$

Fuel Cells

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.122

In Example 13.15, a basic hydrogen–oxygen fuel cell reaction was analyzed at 25°C, 100 kPa. Repeat this calculation, assuming that the fuel cell operates on air at 25°C, 100 kPa, instead of on pure oxygen at this state.

Anode: $2\,H_2 \rightarrow 4\,e^- + 4\,H^+$

Cathode: $4\,H^+ + 4\,e^- \rightarrow 1\,O_2 + 2\,H_2O$

Overall: $2\,H_2 + 1\,O_2 \rightarrow 2\,H_2O$

Example 13.16: $\Delta G_{25°C} = -474\,283$ kJ (for pure O_2)

For $P_{O2} = 0.21 \times 0.1$ MPa:

$\bar{S}_{O_2} = 205.148 - 8.3145 \ln 0.21 = 218.124$ kJ/kmol

$\Delta S = 2(69.950) - 2(130.678) - 1(218.124) = -339.58$ kJ/kmol K

$\Delta G_{25°C} = -571\,660 - 298.15(-339.58) = -470\,414$ kJ/kmol

$$E° = \frac{470414}{96487 \times 4} = \mathbf{1.219\ V}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.123

Assume that the basic hydrogen-oxygen fuel cell operates at 600 K instead of 298 K as in example 13.15. Find the change in the Gibbs function and the reversible EMF it can generate.

Reaction: $2\ H_2 + O_2 \Rightarrow 2\ H_2O$

At a temperature of 600 K the water formed is in a vapor state. We can thus find the change in the enthalpy as

$$\Delta H^0_{600\ K} = 2\left(\bar{h}^o_f + \Delta\bar{h}\right)_{H2O\ g} - 2\left(\bar{h}^o_f + \Delta\bar{h}\right)_{H2} - \left(\bar{h}^o_f + \Delta\bar{h}\right)_{O2}$$

$$= 2(-241\ 826 + 10\ 499) - 2(0 + 8799) - 0 - 9245$$

$$= -489\ 497\ \text{kJ/4 kmol e-}$$

$$\Delta S^0_{600\ K} = 2\,\bar{s}^o_{f\,H2O\ g} - 2\,\bar{s}^o_{f\,H2} - \bar{s}^o_{f\,O2}$$

$$= 2 \times 213.051 - 2 \times 151.078 - 226.45$$

$$= -102.504\ \text{kJ/4 kmol e- K}$$

$$\Delta G^0_{600\ K} = \Delta H^0_{600\ K} - T\Delta S^0_{600\ K} = -489\ 497 - 600(-102.504)$$

$$= -\ 427\ 995\ \text{kJ/4 kmol e-}$$

$$W^{rev} = -\Delta\bar{G}^0 = 427\ 995\ \text{kJ/4 kmol e-}$$

$$E^0 = \frac{-\Delta\bar{G}^0}{96485 \times 8} = \frac{427\ 995}{96\ 485 \times 4} = \mathbf{1.109\ V}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.124

A reversible fuel cell operating with hydrogen and pure oxygen produces water at the reference conditions P_o, T_o; this is described in Example 13.15. Find the work output and any heat transfer, both per kmol of hydrogen. Assume an actual fuel cell operates with a second-law efficiency of 70%, and enough heat transfer takes place to keep it at 25°C. How much heat transfer is that per kmol of hydrogen?

The basic fuel cell analysis from Example 13.15.

Reaction: $\quad 2\ H_2 + O_2 \ \Rightarrow \ 2\ H_2O$

$W^{rev} = -\Delta G = 474\ 283$ kJ/2 kmol = **237 142 kJ/kmol**

This assumed equilibrium with the surroundings so the heat transfer must be

$$Q = T_o\,(S_P - S_R) = 298.15\,(-326.6 / 2) = \mathbf{-48\ 688\ kJ/kmol}$$

that is the heat transfer goes out.

A 70% 2nd law efficiency must mean the actual work is

$$W = 0.7\ W^{rev} = 165\ 999\ \text{kJ/kmol}$$

From the energy equation we get

$$Q = H_P - H_R + W = (-571\ 660/2) + 165\ 999 = \mathbf{-\ 119\ 831\ kJ/kmol}$$

All this heat transfer means that the fuel cell will have a hard time staying at the room temperature it would tend to be warmer.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.125

Consider a methane-oxygen fuel cell in which the reaction at the anode is

$$CH_4 + 2H_2O \rightarrow CO_2 + 8e^- + 8H^+$$

The electrons produced by the reaction flow through the external load, and the positive ions migrate through the electrolyte to the cathode, where the reaction is

$$8\ e^- + 8\ H^+ + 2\ O_2 \rightarrow 4\ H_2O$$

Calculate the reversible work and the reversible EMF for the fuel cell operating at 25°C, 100 kPa.

$$CH_4 + 2H_2O \rightarrow CO_2 + 8e^- + 8H^+$$

and $8e^- + 8H^+ + 2CO_2 \rightarrow 4H_2O$

Overall $CH_4 + 2O_2 \rightarrow CO_2 + 2H_2O$

a) 25 ^oC assume all liquid H_2O and all comp. at 100 kPa

$\Delta H^0_{25\ C}$ = -393 522 + 2(-285 830) – (-74 873) – 0 = -890 309 kJ

$\Delta S^0_{25\ C}$ = 213.795 + 2(69.950) – 186.251 – 2(205.148) = - 242.852 kJ/K

$\Delta G^0_{25\ C}$ = -890 309 – 298.15(-242.852) = - 817 903 kJ

$W^{rev} = -\Delta \bar{G}^0 = +817903$ kJ

$$E^0 = \frac{-\Delta \bar{G}^0}{96485 \times 8} = \frac{+817903}{96485 \times 8} = \mathbf{1.06\ V}$$

13.126

Consider a methane-oxygen fuel cell in which the reaction at the anode is

$$CH_4 + 2H_2O \rightarrow CO_2 + 8e^- + 8H^+$$

The electrons produced by the reaction flow through the external load, and the positive ions migrate through the electrolyte to the cathode, where the reaction is

$$8\ e^- + 8\ H^+ + 2\ O_2 \rightarrow 4\ H_2O$$

Assume that the fuel cell operates at 1200 K instead of at room temperature.

$$CH_4 + 2H_2O \rightarrow CO_2 + 8e^- + 8H^+$$

$$\text{and} \quad 8e^- + 8H^+ + 2CO_2 \rightarrow 4H_2O$$

$$\text{Overall} \quad CH_4 + 2O_2 \rightarrow CO_2 + 2H_2O$$

At 1200 K assume all gas H_2O and all comp. at 100 kPa

$$\Delta H^0_{1200\ K} = 1(-393522 + 44473) + 2(-241826 + 34506) - 2(0 + 29761)$$
$$- 1[-74873 + 16.043 \times 2.254(1200 - 298.2)] = -780\ 948\ \text{kJ}$$

$$\Delta S^0_{1200\ K} = 1(279.390) + 2(240.485)$$
$$- 1(186.251 + 16.043 \times 2.254 \ln \frac{1200}{298.2}) - 2(250.011)$$
$$= 23.7397\ \text{kJ/K}$$

$$\Delta G^0_{1200\ K} = \Delta H^0_{1200\ K} - T\Delta S^0_{1200\ K} = -780\ 948 - 1200(23.7397)$$
$$= -809\ 436\ \text{kJ}$$

$$W^{rev} = \mathbf{+809\ 436\ kJ} \qquad E^0 = \frac{+809\ 436}{96\ 485 \times 8} = \mathbf{1.049\ V}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.127

For a PEC fuel cell operating at 350 K the constants in Eq.13.29 are: i_{leak} = 0.01, i_L = 2, i_o = 0.013 all A/cm^2, b = 0.08 V, c = 0.1 V, ASR = 0.01 Ω cm^2 and EMF = 1.22 V. Find the voltage and the power density for the current density i = 0.25, 0.75 and 1.0 A/cm^2.

The fuel cell output voltage is from Eq.13.29:

$$V = EMF - b \ln \left(\frac{i + i_{leak}}{i_o} \right) - i\, ASR_{ohmic} - c \ln \left(\frac{i_L}{i_L - (i + i_{leak})} \right)$$

i = 0.25: V = 1.22 – 0.23966 – 0.0025 – 0.01393 = 0.9639 V,
p = Vi = 0.241 W/cm^2

i = 0.75: V = 1.22 – 0.32547 – 0.0075 – 0.0478 = 0.8392 V,
p = Vi = 0.6294 W/cm^2

i = 1.0: V = 1.22 – 0.34822 – 0.01 – 0.0703 = 0.7915 V,
p = Vi = 0.7915 W/cm^2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.128

Assume the PEC fuel cell in the previous problem. How large an area does the fuel cell have to deliver 1 kW with a current density of 1 A/ cm^2?

The fuel cell output voltage is from Eq.13.29:

$$V = EMF - b \ln\left(\frac{i + i_{leak}}{i_o}\right) - i\, ASR_{ohmic} - c \ln\left(\frac{i_L}{i_L - (i + i_{leak})}\right)$$

i = 1.0: $V = 1.22 - 0.34822 - 0.01 - 0.0703 = 0.7915$ V,

$p = Vi = 0.7915$ W/cm^2

Total power $P = p\,A = 0.7915$ W/cm^2 $\times$ A = 1000 W

$A = (1000 / 0.7915)$ cm^2 = **1263 cm^2**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.129

A SOC fuel cell at 900 K can be described by an EMF = 1.06 V and the constants in Eq.13.29 as : b = 0 V, c = 0.1 V, ASR = 0.04 Ω cm^2, i_{leak} = 0.01, i_L = 2, i_o = 0.13 all A/cm^2. Find the voltage and the power density for the current density i = 0.25, 0.75 and 1.0 A/cm^2.

The fuel cell output voltage is from Eq.13.29:

$$V = EMF - b \ln \left(\frac{i + i_{leak}}{i_o} \right) - i\, ASR_{ohmic} - c \ln \left(\frac{i_L}{i_L - (i + i_{leak})} \right)$$

i = 0.25: V = 1.06 – 0.0 – 0.01 – 0.01393 = 1.036 V,
p = Vi = 0.259 W/cm^2

i = 0.75: V = 1.06 – 0.0 – 0.03 – 0.0478 = 0.9822 V,
p = Vi = 0.737 W/cm^2

i = 1.0: V = 1.06 – 0.0 – 0.04 – 0.0703 = 0.95 V,
p = Vi = 0.95 W/cm^2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.130

Assume the SOC fuel cell in the previous problem. How large an area does the fuel cell have to deliver 1 kW with a current density of 1 A/ cm^2?

The fuel cell output voltage is from Eq.13.29:

$$V = EMF - b \ln \left(\frac{i + i_{leak}}{i_o} \right) - i\, ASR_{ohmic} - c \ln \left(\frac{i_L}{i_L - (i + i_{leak})} \right)$$

i = 1.0: $V = 1.06 - 0.0 - 0.04 - 0.0703 = 0.95$ V,

$p = Vi = 0.95$ W/cm^2

Total power $P = p\,A = 0.95$ W/cm^2 $\times$ A = 1000 W

$A = (1000 / 0.95)$ cm^2 = **1053 cm^2**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.131

A PEC fuel cell operating at 25°C, generates 1.0 V that also account for losses. For a total power of 1 kW what is the hydrogen mass flow rate?

The work term for the fuel cell is

$$W = -\Delta G^0_{298\ K} \qquad \text{so} \quad \dot{W} = -\dot{n}\,\Delta G^0_{298\ K}$$

$$\dot{m} = M\dot{n} = \frac{M\dot{W}}{-\Delta G^0_{298\ K}} = \frac{2.016\ \text{kg/kmol} \times 1\ \text{kW}}{0.5 \times 474\ 283\ \text{kJ/kmol}} = 8.5 \times 10^{-6}\ \text{kg/s}$$

Since the actual output was 1 V rather than the ideal 1.229 V we then infer an efficiency of (1/1.229 = 0.814) so

$$\dot{m}_{ac} = \dot{m} / 0.814 = \mathbf{10.45 \times 10^{-6}\ kg/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.132

A basic hydrogen-oxygen fuel cell operates at 600 K instead of 298 K as in example 13.15. For a total power of 5 kW, find the hydrogen mass flow rate and the exergy in the exhaust flow.

Reaction: $2\,H_2 + O_2 \Rightarrow 2\,H_2O$

At a temperature of 600 K the water formed is in a vapor state. We can thus find the change in the enthalpy as

$$\Delta H^0_{600\,K} = 2\left(\bar{h}^o_f + \Delta\bar{h}\right)_{H2O\,g} - 2\left(\bar{h}^o_f + \Delta\bar{h}\right)_{H2} - \left(\bar{h}^o_f + \Delta\bar{h}\right)_{O2}$$

$$= 2(-241\,826 + 10\,499) - 2(0 + 8799) - 0 - 9245$$

$$= -489\,497 \text{ kJ/4 kmol e-}$$

$$\Delta S^0_{600\,K} = 2\,\bar{s}^o_{f\,H2O\,g} - 2\,\bar{s}^o_{f\,H2} - \bar{s}^o_{f\,O2}$$

$$= 2 \times 213.051 - 2 \times 151.078 - 226.45$$

$$= -102.504 \text{ kJ/4 kmol e- K}$$

$$\Delta G^0_{600\,K} = \Delta H^0_{600\,K} - T\Delta S^0_{600\,K} = -489\,497 - 600(-102.504)$$

$$= -\,427\,995 \text{ kJ/4 kmol e-}$$

$$W^{rev} = -\Delta\bar{G}^0 = 427\,995 \text{ kJ/4 kmol e-}$$

This was for 2 kmol hydrogen

$$\dot{m} = M\dot{n} = \frac{M\dot{W}}{-\Delta G^0_{600\,K}} = \frac{2.016 \text{ kg/kmol} \times 5 \text{ kW}}{0.5 \times 427\,995 \text{ kJ/kmol}} = \mathbf{47.1 \times 10^{-6}\ kg/s}$$

The exhaust flow is water vapor at 600 K, 100 kPa so use Table B.1

$$\dot{m}\psi = \dot{m}\,[(h - h_o - T_o(s - s_o)]$$

$$= 47.1 \times 10^{-6}\,[3129 - 104.87 - 298.15\,(8.3037 - 0.3673)]$$

$$= \mathbf{0.031\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.133

Consider the fuel cell with methane in Problem 13.125. Find the work output and any heat transfer, both per kmol of methane. Assume an actual fuel cell operates with a second-law efficiency of 75%, and enough heat transfer takes place to keep it at 25°C. How much heat transfer is that per kmol of methane?

$$CH_4 + 2H_2O \rightarrow CO_2 + 8e^- + 8H^+$$

and $$8e^- + 8H^+ + 2CO_2 \rightarrow 4H_2O$$

Overall reaction: $$CH_4 + 2O_2 \rightarrow CO_2 + 2H_2O$$

T = 25 ^oC = 298 K, assume all liquid H_2O and all comp. at 100 kPa

$$\Delta H^0_{25\ C} = -393\ 522 + 2(-285\ 830) - (-74\ 873) - 0 = -890\ 309\ kJ/kmol$$

$$\Delta S^0_{25\ C} = 213.795 + 2(69.950) - 186.251 - 2(205.148) = -242.852\ kJ/K$$

$$\Delta G^0_{25\ C} = -890\ 309 - 298.15(-242.852) = -817\ 903\ kJ/kmol$$

$$W^{rev} = -\Delta \bar{G}^0 = +817\ 903\ kJ/kmol$$

This assumed equilibrium with the surroundings so the heat transfer must be

$$Q = T_o\ (S_P - S_R) = 298.15\ (-242.852) = \mathbf{-72\ 406\ kJ/kmol}$$

A 75% 2nd law efficiency must mean the actual work is

$$W = 0.75\ W^{rev} = 613\ 427\ kJ/kmol$$

From the energy equation we get

$$Q = H_P - H_R + W = (-890\ 309) + 613\ 427 = \mathbf{-\ 276\ 881\ kJ/kmol}$$

All this heat transfer means that the fuel cell will have a hard time staying at the room temperature it would tend to be warmer.

Combustion applications and efficiency

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.134

For the combustion of methane 150% theoretical air is used at 25°C, 100 kPa and relative humidity of 70%. Find the composition and dew point of the products.

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + 3.76\,\nu_{O2}\,N_2$$

C balance: $\nu_{CO2} = 1$, H balance: $2\nu_{H2O} = 4$, N_2 balance: $\nu_{N2} = 3.76\,\nu_{O2}$

O balance: $2\,\nu_{O2} = \nu_{H2O} + 2\nu_{CO2} = 2 + 2 \times 1 \quad => \quad \nu_{O2} = 2$

150% theoretical air: $\nu_{O2} = 1.5 \times 2 = 3$ so now more O_2 and N_2

$$CH_4 + 3\,(O_2 + 3.76\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + 11.28\,N_2 + 1\,O_2$$

Add water to the dry air from Eq.11.28

$$w = 0.622\,\frac{\phi P_g}{P_{tot} - \phi P_g} = 0.622\,\frac{0.7 \times 3.169}{100 - 0.7 \times 3.169} = 0.0141$$

So the number of moles to add is from Eq.13.32

$$x = 7.655\,w = 7.655 \times 0.0141 = 0.108$$

and the added number of moles is $\nu_{O2}\,x = 0.324$, the products are then

Products: $2.324\,H_2O + 1\,CO_2 + 11.28\,N_2 + 1\,O_2$

The water partial pressure becomes

$$P_v = y_v\,P_{tot} = \frac{2.324}{2.324 + 1 + 11.28 + 1}\,100 = 14.894\ \text{kPa}$$

$$T_{dew} = \mathbf{53.8^oC}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.135

Pentane is burned with 120% theoretical air in a constant pressure process at 100 kPa. The products are cooled to ambient temperature, 20°C. How much mass of water is condensed per kilogram of fuel? Repeat the answer, assuming that the air used in the combustion has a relative humidity of 90%.

$$C_5H_{12} + 1.2 \times 8\,(O_2 + 3.76\,N_2) \rightarrow 5\,CO_2 + 6\,H_2O + 0.96\,O_2 + 36.1\,N_2$$

Products cooled to 20°C, 100 kPa, so for H_2O at 20°C: $P_g = 2.339$ kPa

$$y_{H2O\ MAX} = P_g/P = \frac{2.339}{100} = \frac{n_{H2O\ MAX}}{n_{H2O\ MAX} + 42.06} \quad \Rightarrow \quad n_{H2O\ MAX} = 1.007 < n_{H2O}$$

Therefore, $n_{H2O\ VAP} = 1.007$, $n_{H2O\ LIQ} = 6 - 1.007 = 4.993$

$$m_{H2O\ LIQ} = \frac{4.993 \times 18.015}{72.151} = \mathbf{1.247\ kg/kg\ fuel}$$

$$P_{v1} = 0.9 \times 2.339 = 2.105\ \text{kPa} \quad \Rightarrow \quad w_1 = 0.622 \times \frac{2.105}{97.895} = 0.013375$$

Water from moist air, Eq. 13.32

$$n_{H2O\ IN} = 0.013375 \times \frac{28.97}{18.015} \times 9.6\,(1 + 3.76) = 0.983\ \text{kmol}$$

$$n_{H2O\ OUT} = 0.983 + 6 = 6.983 \quad \Rightarrow \quad n_{H2O\ LIQ} = 6.983 - 1.007 = 5.976\ \text{kmol}$$

$$m_{H2O\ LIQ} = \frac{5.976 \times 18.015}{72.151} = \mathbf{1.492\ kg/kg\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.136

A gas turbine burns methane with 150% theoretical air. Assume the air is 25°C, 100 kPa and relative humidity of 80%. How large a fraction of the product mixture water comes from the moist inlet air?

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + 3.76\,\nu_{O2}\,N_2$$

C balance: $\nu_{CO2} = 1$, H balance: $2\nu_{H2O} = 4$, N_2 balance: $\nu_{N2} = 3.76\,\nu_{O2}$

O balance: $2\,\nu_{O2} = \nu_{H2O} + 2\nu_{CO2} = 2 + 2 \times 1 \quad => \quad \nu_{O2} = 2$

150% theoretical air: $\nu_{O2} = 1.5 \times 2 = 3$ so now more O_2 and N_2

$$CH_4 + 3\,(O_2 + 3.76\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + 11.28\,N_2 + 1\,O_2$$

Add water to the dry air from Eq.11.28-29

$$w = 0.622\,\frac{\phi P_g}{P_{tot} - \phi P_g} = 0.622\,\frac{0.7 \times 3.169}{100 - 0.7 \times 3.169} = 0.0141$$

So the number of moles to add is from Eq.13.32

$$x = 7.655\,w = 7.655 \times 0.0141 = 0.108$$

and the added number of moles is $\nu_{O2}\,x = 0.324$, the products are then

Products: $2.324\,H_2O + 1\,CO_2 + 11.28\,N_2 + 1\,O_2$

Fraction of water is 0.324/2.324 = 0.1394 so **13.9%**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.137

In an engine a mixture of liquid octane and ethanol, mole ratio 9:1, and stoichiometric air are taken in at T_0, P_0. In the engine the enthalpy of combustion is used so that 30% goes out as work, 30% goes out as heat loss and the rest goes out the exhaust. Find the work and heat transfer per kilogram of fuel mixture and also the exhaust temperature.

$$0.9\ C_8H_{18} + 0.1\ C_2H_5OH + 11.55\ O_2 + 43.428\ N_2 \rightarrow 8.4\ H_2O + 7.4\ CO_2 + 43.428\ N_2$$

For 0.9 octane + 0.1 ethanol, convert to mole basis

$$\bar{H}^\circ_{RP\ mix} = 0.9\ \bar{H}^\circ_{RP\ C_8H_{18}} + 0.1\ \bar{H}^\circ_{RP\ C_2H_5OH}$$

$$= 0.9\ (-44\ 425) \times 114.232 + 0.1\ (-26\ 811) \times 46.069$$

$$= -4\ 690\ 797\ \frac{kJ}{kmol}$$

$$\hat{M}_{mix} = 0.9\ \hat{M}_{oct} + 0.1\ \hat{M}_{alc} = 107.414$$

Energy: $\bar{h}^\circ_{in} + q_{in} = \bar{h}_{ex} + \omega_{ex} = \bar{h}^\circ_{ex} + \Delta\bar{h}_{ex} + \omega_{ex}$

$$\bar{h}^\circ_{ex} - \bar{h}^\circ_{in} = \bar{H}^\circ_{RP\ mix} \quad \Rightarrow \quad \omega_{ex} + \Delta\bar{h}_{ex} - q_{in} = -\bar{H}^\circ_{RP\ mix}$$

$$\omega_{ex} = -q_{in} = 0.3\left(-\bar{H}^\circ_{RP}\right) = \mathbf{1\ 407\ 239\ \frac{kJ}{kmol}} = \mathbf{13\ 101\ \frac{kJ}{kg\ Fu}}$$

$$\Delta\bar{h}_{prod} = \Delta\bar{h}_{ex} = 0.4\left(-\bar{H}^\circ_{RP}\right) = 1\ 876\ 319\ \frac{kJ}{kmol\ Fu}$$

$$\Delta\bar{h}_{prod} = 8.4\ \Delta\bar{h}_{H_2O} + 7.4\Delta\bar{h}_{CO_2} + 43.428\ \Delta\bar{h}_{N_2}$$

$$\Delta\bar{h}_{prod\ 1300} = 8.4 \times 38\ 941 + 7.4 \times 50\ 148 + 43.428 \times 31\ 503 = 2\ 066\ 312$$

$$\Delta\bar{h}_{prod\ 1200} = 8.4 \times 34\ 506 + 7.4 \times 44\ 473 + 43.428 \times 28\ 109 = 1\ 839\ 668$$

Linear interpolation to get the value of $\Delta\bar{h}_{prod} = 1\ 876\ 319$

$\Rightarrow$ satisfied for T = **1216 K**

13.138

The gas turbine cycle in problem 10.28 has a q_H = 1160 kJ/kg air added by combustion. Assume the fuel is methane gas and the q_H equals the heating value at T_o. Find the A/F ratio on a mass basis.

The heating value and the q_H are scaled with the fuel mass and total mixture mass respectively so the relation is, see Eq.13.34,

$$q_H = \frac{HV}{m_{mix}/m_{fuel}} = \frac{HV}{A/F + 1} = 1160 \text{ kJ/kg-mix}$$

$$A/F = \frac{HV}{q_H} - 1 = \frac{50\ 010}{1160} - 1 = \mathbf{43.11}$$

Comment: This is about 300% theoretical air.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.139

An oven heated by natural gas burners has the combustion take place inside a U-shaped steel pipe, so the heating is done from the outside surface of the pipe by radiation. Each burner delivers 15 kW of radiation, burning 110% theoretical air with methane. The products leave the pipe at 800 K. Find the flow(kg/s) of methane. The burner is now switched to oxygen-enriched air (30% O_2 and 70% N_2), so assume the same conditions as before with the same exit T. Find the new flow (kg/s) of methane needed.

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2} (O_2 + 3.76\, N_2) \rightarrow 2\, H_2O + 1\, CO_2 + c\, N_2$$

O balance: $2\, \nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2$

110% theoretical air: $\nu_{O2} = 1.1 \times 2 = 2.2$ so now more O_2 and N_2

$$CH_4 + 2.2 (O_2 + 3.76\, N_2) \rightarrow 2\, H_2O + 1\, CO_2 + 8.272\, N_2 + 0.2\, O_2$$

Energy Eq. assume reactant enter at reference T:

$$Q_{CV} = H_P - H_R = \overset{\circ}{H}_P + \Delta H_P - \overset{\circ}{H}_R = \overset{\circ}{H}_{RP} + \Delta H_P$$

$$\Delta H_P = 2\, \Delta\bar{h}_{H2O} + \Delta\bar{h}_{CO_2} + 8.272\, \Delta\bar{h}_{N_2} + 0.2\, \Delta\bar{h}_{O_2}$$

$$= 2 \times 18002 + 22806 + 8.272 \times 15046 + 0.2 \times 15836 = 186\,438 \text{ kJ/kmol}$$

$$\overset{\circ}{H}_{RP} = 16.043 \times (-50\,010) = -802\,310 \text{ kJ/kmol}$$

$$Q_{CV} = -802\,310 + 186\,438 = -615\,872 \text{ kJ/kmol},$$

$$\dot{m} = M\, \dot{Q}_{CV} / -Q_{CV} = 16.043 \times 15 / 615\,872 \text{ kg/s} = \mathbf{0.00039\ kg/s}$$

The new "air" just changes the nitrogen to oxygen ratio to 70/30 = 2.333 so the actual reaction is changed to:

$$CH_4 + 2.2 (O_2 + 2.333\, N_2) \rightarrow 2\, H_2O + 1\, CO_2 + 5.1333\, N_2 + 0.2\, O_2$$

$$\Delta H_P = 2\, \Delta\bar{h}_{H2O} + \Delta\bar{h}_{CO_2} + 5.1333\, \Delta\bar{h}_{N_2} + 0.2\, \Delta\bar{h}_{O_2}$$

$$= 2 \times 18002 + 22806 + 5.1333 \times 15046 + 0.2 \times 15836 = 139\,213 \text{ kJ/kmol}$$

$$Q_{CV} = -802\,310 + 139\,213 = -663\,097 \text{ kJ/kmol},$$

$$\dot{m} = M\, \dot{Q}_{CV} / -Q_{CV} = 16.043 \times 15 / 663\,097 \text{ kg/s} = \mathbf{0.00036\ kg/s}$$

This is an 8% reduction in the fuel flow rate.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.140

A slight disadvantage of the oxygen-enriched air for combustion is an increase in flame temperature, which tends to increase NOx. Find the flame temperature for the previous problem for both cases, standard air and oxygen-enriched air.

Energy Eq. assume reactant enter at reference T:

$$0 = H_P - H_R = H_P^\circ + \Delta H_P - H_R^\circ = H_{RP}^\circ + \Delta H_P$$

$$\Delta H_P = -H_{RP}^\circ = HV = 16.043 \times (50\ 010) = 802\ 310 \text{ kJ/kmol}$$

Reaction std. air:

$$CH_4 + 2.2\,(O_2 + 3.76\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + 8.272\,N_2 + 0.2\,O_2$$

$$\Delta H_P = 2\,\Delta\bar{h}_{H2O} + \Delta\bar{h}_{CO_2} + 8.272\,\Delta\bar{h}_{N_2} + 0.2\,\Delta\bar{h}_{O_2}$$

The heating value should be spread over 11.47 moles of products which is about 70 000 each so look in A.9 for oxygen or nitrogen T = 2200 – 2400 K.

$$\Delta H_{P\ 2200K} = 2 \times 83153 + 103562 + 8.272 \times 63362 + 0.2 \times 66770 = 807\ 352$$

$$\Delta H_{P\ 2000K} = 2 \times 72788 + 91\ 439 + 8.272 \times 56137 + 0.2 \times 59176 = 713\ 215$$

Interpolate T = **2189 K**

Reaction std. air:

$$CH_4 + 2.2\,(O_2 + 2.333\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + 5.1333\,N_2 + 0.2\,O_2$$

$$\Delta H_P = 2\,\Delta\bar{h}_{H2O} + \Delta\bar{h}_{CO_2} + 5.1333\,\Delta\bar{h}_{N_2} + 0.2\,\Delta\bar{h}_{O_2}$$

The heating value should be spread over 8.333 moles of products which is about 96 000 each so look in A.9 for oxygen or nitrogen T ≈ 3000 K.

$$\Delta H_{P\ 3000K} = 2 \times 126\ 548 + 152\ 853 + 5.1333 \times 92715 + 0.2 \times 98\ 013 = 901\ 485$$

$$\Delta H_{P\ 2800K} = 2 \times 115\ 463 + 140\ 435 + 5.1333 \times 85\ 323 + 0.2 \times 90\ 080 = 827\ 366$$

$$\Delta H_{P\ 2600K} = 2 \times 104\ 520 + 128\ 074 + 5.1333 \times 77\ 963 + 0.2 \times 82\ 225 = 753\ 766$$

Interpolate T = **2732 K** a significant higher flame temperature.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.141

A gas turbine burns methane with 200% theoretical air. The air and fuel comes in through two separate compressors bringing them from 100 kPa, 298 K to 1400 kPa and enters a mixing chamber and combustion chamber. What are the specific compressor work and q_H to be used in Brayton cycle calculation? Use constant specific heat to solve.

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2} (O_2 + 3.76\, N_2) \rightarrow 2\, H_2O + 1\, CO_2 + c\, N_2$$

O balance: $2\, \nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2$

200% theoretical air: $\nu_{O2} = 2 \times 2 = 4$ so now more O_2 and N_2

$$CH_4 + 4 (O_2 + 3.76\, N_2) \rightarrow 2\, H_2O + 1\, CO_2 + 15.04\, N_2 + 2\, O_2$$

For 1 kmol fuel: $m = 16.043 + 4 \times 4.76 \times 28.97$

$= 16.043 + 551.59 = 567.63$ kg reactants

The temperatures after compression are:

$$T_{2\,air} = T_1 (P_2/P_1)^{(k-1)/k} = 298.15 \times 14^{0.2857} = 633.7 \text{ K} \qquad (k = 1.4)$$

$$T_{2\,fuel} = T_1 (P_2/P_1)^{(k-1)/k} = 298.15 \times 14^{0.230177} = 547.3 \text{ K} \quad (k = 1.299)$$

$$w_{c\,air} = C_p (T_2 - T_1) = 1.004(633.7 - 298.15) = 336.89 \text{ kJ/kg air}$$

$$w_{c\,fuel} = C_p (T_2 - T_1) = 2.254(547.3 - 298.15) = 561.68 \text{ kJ/kg fuel}$$

$$w_{c\,total} = \frac{m_{fuel}}{m} w_{c\,fuel} + \frac{m_{air}}{m} w_{c\,air} = \frac{16.04}{567.63} 561.58 + \frac{551.59}{567.63} 336.89$$

$$= \mathbf{343.24\ kJ/kg\ mix}$$

$q = -\overset{\circ}{H}_{RP} = HV$ but scaled to be per kg reactants

$$q = \frac{50\,010 \times 16.043}{567.63} = \mathbf{1413.4\ kJ/kg} \quad \left(= \frac{HV}{A/F + 1} \right)$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.142

Find the equivalent heat transfer q_H to be used in a cycle calculation for constant pressure combustion when the fuel is (a) methane and (b) gaseous octane in both cases use water vapor in the products and a stoichiometric mixture.

Methane combustion becomes

$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 1\,CO_2 + 2\,H_2O + 7.52\,N_2$$

Oxygen balance: $2\nu_{O2} = 2 + 2 = 4 \Rightarrow \nu_{O2} = 2, \quad \nu_{N2} = 7.52$

$$A/F = \frac{2 \times 31.999 + 7.52 \times 28.013}{16.043} = 17.12 = m_{air}/m_{fuel}$$

$$q = \frac{HV}{m_{mix}/m_{fuel}} = \frac{HV}{A/F + 1} = \frac{50\,010}{17.12 + 1} = \mathbf{2760\ kJ/kg}$$

Octane combustion, see reaction and A/F in Example 13.1, HV from Table 13.3

$$q = \frac{HV}{m_{mix}/m_{fuel}} = \frac{HV}{A/F + 1} = \frac{44\,788}{15 + 1} = \mathbf{2799\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.143

Consider the steady combustion of propane at 25°C with air at 400 K. The products exit the combustion chamber at 1200 K. It may be assumed that the combustion efficiency is 90%, and that 95% of the carbon in the propane burns to form carbon dioxide; the remaining 5% forms carbon monoxide. Determine the ideal fuel–air ratio and the heat transfer from the combustion chamber.

Ideal combustion process, assumed adiabatic, excess air to keep 1200 K out.

$$C_3H_8 + 5x\ O_2 + 18.8x\ N_2 \rightarrow 3\ CO_2 + 4\ H_2O + 5(x - 1)\ O_2 + 18.8x\ N_2$$

$$H_R = -103900 + 5x(0 + 3027) + 18.8x(0 + 2971) = -103900 + 70990x$$

$$H_P = 3(-393522 + 44473) + 4(-241826 + 34506)$$

$$+ 5(x - 1)(0 + 29761) + 18.8x(0 + 28109) = -2025232 + 677254x$$

Energy Eq.: $H_P - H_R = 0$ Solving, x = 3.169

$$FA_{IDEAL} = 1/(23.8 \times 3.169) = \mathbf{0.01326}$$

$$FA_{ACTUAL} = 0.01326/0.90 = 0.01473$$

$$C_3H_8 + 14.26\ O_2 + 53.62\ N_2$$

$$\rightarrow 2.85\ CO_2 + 0.15\ CO + 4\ H_2O + 9.335\ O_2 + 53.62\ N_2$$

$$H_R = -103900 + 14.26(0 + 3027) + 53.62(0 + 2971) = +98\ 570\ kJ$$

$$H_P = 2.85(-393522 + 44473) + 0.15(-110527 + 28427) + 4(-241826 + 34506)$$

$$+ 9.335(0 + 29761) + 53.62(0 + 28109) = -51\ 361\ kJ$$

$$Q_{CV} = H_P - H_R = \mathbf{-149\ 931\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.144

A gasoline engine is converted to run on propane. Assume the propane enters the engine at 25°C, at the rate 40 kg/h. Only 90% theoretical air enters at 25°C such that 90% of the C burns to form CO_2, and 10% of the C burns to form CO. The combustion products also include H_2O, H_2 and N_2, exit the exhaust at 1000 K. Heat loss from the engine (primarily to the cooling water) is 120 kW. What is the power output of the engine? What is the thermal efficiency?

Propane: $T_1 = 25^oC$, $\dot{m} = 40$ kg/hr, M = 44.094 kg/kmol

Air: $T_2 = 25^oC$, 90% theoretical Air produces 90% CO_2, 10% CO

Products: $T_3 = 1000$ K, CO_2, CO, H_2O, H_2, N_2

$C_3H_8 + 4.5O_2 + 16.92N_2 \rightarrow 2.7\ CO_2 + 0.3CO + 3.3H_2O + 0.7H_2 + 16.92N_2$

$\dot{n}_{C3H8} = \dot{m}/(M \times 3600) = 0.000252$ kmol/s

Energy eq.: $\dot{Q} + H_R = H_p + \dot{W}$; $\dot{Q} = -120$ kW

$H_R = n_{C3H8}\ \bar{h}_f^o = -103\ 900$ kJ

Products:

CO_2 - $n_{CO2}\left(\bar{h}_f^o + \Delta\bar{h}\right) = 2.7(-393522 + 33397) = -972337.5$ kJ

CO - $n_{CO}\left(\bar{h}_f^o + \Delta\bar{h}\right) = 0.3(-110527 + 21686) = -26652$ kJ

H_2O - $n_{H2O}\left(\bar{h}_f^o + \Delta\bar{h}\right) = 3.3(-241826 + 26000) = -712226$ kJ

H_2 - $n_{H2}\left(\bar{h}_f^o + \Delta\bar{h}\right) = 0.7(0 + 20663) = 14464.1$ kJ

N_2 - $n_{N2}\left(\bar{h}_f^o + \Delta\bar{h}\right) = 16.92(0 + 21463) = 363154$ kJ

$H_P = \sum n_i \left(\bar{h}_f^o + \Delta\bar{h}\right)_i = -1\ 333\ 598$ kJ

$\dot{W} = \dot{Q} + \dot{n}(H_R - H_P) =$ **189.9 kW**

C_3H_8: Table 13.3 $H_{RPo} = -50343$ kJ/kg

$H\dot{H}V = \dot{n}_{C3H8}\ M(-H_{RPo}) = 559.4$ kW

$\eta_{th} = \dot{W}/H\dot{H}V =$ **0.339**

13.145

A small air-cooled gasoline engine is tested, and the output is found to be 1.0 kW. The temperature of the products is measured to 600 K. The products are analyzed on a dry volumetric basis, with the result: 11.4% CO_2, 2.9% CO, 1.6% O_2 and 84.1% N_2. The fuel may be considered to be liquid octane. The fuel and air enter the engine at 25°C, and the flow rate of fuel to the engine is 1.5×10^{-4} kg/s. Determine the rate of heat transfer from the engine and its thermal efficiency.

$$a\, C_8H_{18} + b\, O_2 + 3.76b\, N_2$$
$$\rightarrow 11.4\, CO_2 + 2.9\, CO + c\, H_2O + 1.6\, O_2 + 84.1\, N_2$$

$$b = \frac{84.1}{3.76} = 22.37, \qquad a = \frac{1}{8}(11.4 + 2.9) = 1.788$$

$$c = 9a = 16.088$$

$$C_8H_{18} + 12.5\, O_2 + 47.1\, N_2$$
$$\rightarrow 6.38\, CO_2 + 1.62\, CO + 9\, H_2O + 0.89\, O_2 + 47.1\, N_2$$

$$H_R = \bar{h}^0_{f\, C_8H_{18}} = -250\,105 \text{ kJ/kmol}$$

$$H_P = 6.38(-393\,522 + 15\,788) + 1.62(-110527 + 10\,781)$$
$$+ 9(-241\,826 + 12\,700) + 0.89(0 + 11187)$$
$$+ 47.1(0 + 10712) = -4\,119\,174 \text{ kJ/kmol}$$

$$H_P - H_R = -4\,119\,174 - (-250\,105) = -3\,869\,069 \text{ kJ/kmol}$$

$$\dot{H}_P - \dot{H}_R = (0.00015/114.23)(-3\,869\,069) = -5.081 \text{ kW} \quad (M_{fuel} = 114.23)$$

$$\dot{Q}_{CV} = -5.081 + 1.0 = \mathbf{-4.081\ kW}$$

Fuel heating value from table 13.3

$$\dot{Q}_H = \dot{m}\, HV = 0.00015\ (47\,893) = 7.184 \text{ kW}$$

$$\eta_{TH} = \dot{W}_{NET}/\dot{Q}_H = 1.0/7.184 = \mathbf{0.139}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.146

A gasoline engine uses liquid octane and air, both supplied at P_0, T_0, in a stoichiometric ratio. The products (complete combustion) flow out of the exhaust valve at 1100 K. Assume that the heat loss carried away by the cooling water, at 100°C, is equal to the work output. Find the efficiency of the engine expressed as (work/lower heating value) and the second law efficiency.

$$C_8H_{18} + \nu_{O_2}(O_2 + 3.76\ N_2) \rightarrow 8\ CO_2 + 9\ H_2O + 47\ N_2$$

$$2\ \nu_{O_2} = 16 + 9 \Rightarrow \nu_{O_2} = 12.5$$

$$\text{LHV} = 44\,425 \frac{\text{kJ}}{\text{kg fuel}} \Rightarrow \text{LHV} = 5.07476\times10^6 \frac{\text{kJ}}{\text{kmol fuel}}$$

$$\Delta H_{P\ 1100} = 8 \times 38885 + 9 \times 30190 + 47 \times 24760 = 1746510$$

C.V. Total engine

$$H_{in} = H_{ex} + W + Q_{loss} = H_{ex} + 2\ W$$

$$\Rightarrow 2\ W = H_{in} - H_{ex} = H_R - H_\nu = -H^\circ_{RP} + \Delta H_R - \Delta H_{P\ 1100}$$

$$= 5.07476\times10^6 + 0 - 1746510 = 3328250$$

$$W = 1.664\times10^6 \frac{\text{kJ}}{\text{kmol fuel}}$$

$$\eta_{th} = \frac{W}{\text{LHV}} = \frac{1.664\times10^6}{5.07476\times10^6} = \mathbf{0.328}$$

Find entropies in and out:

inlet:

$$\bar{S}^\circ_{Fu} = 360.575$$

$$\bar{S}^\circ_{O_2} = 205.148 - 8.3145 \ln \frac{1}{4.76} = 218.12$$

$$\bar{S}^\circ_{N_2} = 191.609 - 8.3145 \ln \frac{3.76}{4.76} = 193.57$$

$$\bar{S}^\circ_{in} = 360.575 + 12.5 \times 218.12 + 47 \times 193.57 = 12185$$

exit: $\bar{S}^\circ_{CO_2} = 275.528 - 8.3145 \ln \frac{8}{64} = 292.82$

$$\bar{S}^\circ_{H_2O} = 236.732 - 8.3145 \ln \frac{9}{64} = 253.04$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$\bar{S}^{\circ}_{N_2} = 231.314 - 8.1345 \ln \frac{47}{64} = 233.88$$

$$\bar{S}^{\circ}_{ex} = 8 \times 292.82 + 9 \times 253.04 + 47 \times 233.88 = 15612$$

Assume the same Q_{loss} out to 100°C reservoir in the reversible case and compute Q_0^{rev}:

$$\bar{S}_{in} + Q_0^{rev}/T_0 = \bar{S}_{ex} + Q_{loss}/T_{res}$$

$$Q_0^{rev} = T_0\left(\bar{S}_{ex} - \bar{S}_{in}\right) + Q_{loss}\, T_0/T_{res}$$

$$= 298.15(15612 - 12185) + 1.664\times10^6 \times 298.15/373.15$$

$$= 2.351\times10^6 \frac{\text{kJ}}{\text{kmol fuel}}$$

$$H_{in} + Q_0^{rev} = H_{ex} + W^{rev} + Q_{loss}$$

$$\Rightarrow W^{rev} = H_{in} - H_{ex} - Q_{loss} + Q_0^{rev} = W_{ac} + Q_0^{rev} = 4.015\times10^6 \frac{\text{kJ}}{\text{kmol fuel}}$$

$$\eta_{II} = W_{ac}/ W^{rev} = 1.664\times10^6/4.015\times10^6 = \mathbf{0.414}$$

13.147

Repeat Problem 13.26 for a certain Utah coal that contains, according to the coal analysis, 68.2% C, 4.8% H, 15.7% O on a mass basis. The exiting product gas contains 30.9% CO, 26.7% H_2, 15.9% CO_2 and 25.7% H_2O on a mole basis.

Convert the mass concentrations to number of kmol per 100 kg coal:

C : 68.2/12.01 = 5.679 $\qquad$ H_2: 4.8/2.016 = 2.381

O_2: 15.7/32.00 = 0.491

Now the combustion equation reads

$$x(5.679\,C + 2.381\,H_2 + 0.491\,O_2) + y\,H_2O + z\,O_2 \text{ in}$$

$$30.9\,CO + 26.7\,H_2 + 15.9\,CO_2 + 25.7\,H_2O \text{ out}$$

in 100 kmol of mix out

Now we can do the atom balance to find (x, y, z)

C : $\quad 5.679x = 30.9 + 15.9 \quad \rightarrow \quad x = 8.241$

H_2: $\quad 2.381 \times 8.241 + y = 26.7 + 25.7 \quad \rightarrow \quad y = 32.778$

$$O_2: \quad 0.491 \times 8.241 + \frac{32.778}{2} + z = \frac{30.9}{2} + 15.9 + \frac{25.7}{2}$$

$$\rightarrow \quad z = 23.765$$

Therefore, for 100 kmol of mixture out,

require: **824.1 kg** of coal

32.778 kmol of steam

23.765 kmol of oxygen

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.148

Many coals from the western United States have a high moisture content. Consider the following sample of Wyoming coal, for which the ultimate analysis on an as-received basis is, by mass:

Component	Moisture	H	C	S	N	O	Ash
% mass	28.9	3.5	48.6	0.5	0.7	12.0	5.8

This coal is burned in the steam generator of a large power plant with 150% theoretical air. Determine the air–fuel ratio on a mass basis.

Converting from mass analysis:

Substance	S	H_2	C	O_2	N_2
c/M =	0.5/32	3.5/2	4.86/12	12/32	0.7/28
kmol / 100 kg coal	0.0156	1.75	4.05	0.375	0.025
Product	SO_2	H_2O	CO_2		
oxygen required	0.0156	0.875	4.05	--	--

Combustion requires then oxygen as: $0.0156 + 0.875 + 4.05 = 4.9406$

The coal does include $0.375\ O_2$ so only $4.5656\ O_2$ from air/100 kg coal

AF = $1.5 \times (4.5656 + 4.5656 \times 3.76) \times 28.97/100 =$ **9.444 kg air/kg coal**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.149

A fuel, C_xH_y, is burned with dry air and the product composition is measured on a dry mole basis to be: 9.6% CO_2, 7.3% O_2 and 83.1% N_2. Find the fuel composition (*x*/*y*) and the percent theoretical air used.

$$\nu_{Fu}C_xH_y + \nu_{O_2}O_2 + 3.76\nu_{O_2}N_2 \rightarrow 9.6\ CO_2 + 7.3\ O_2 + 83.1\ N_2 + \nu_{H_2O}H_2O$$

N_2 balance: $3.76\nu_{O_2} = 83.1 \Rightarrow \nu_{O_2} = \mathbf{22.101}$

O_2 balance: $\nu_{O_2} = 9.6 + 7.3 + \frac{1}{2}\nu_{H_2O} \Rightarrow \nu_{H_2O} = \mathbf{10.402}$

H balance: $\nu_{Fu}\, y = 2\ \nu_{H_2O} = \mathbf{20.804}$

C balance: $\nu_{Fu}\, x = \mathbf{9.6}$

Fuel composition ratio = x/y = 9.6/20.804 = **0.461**

$$\text{Theoretical air} = \frac{\nu_{O_2AC}}{\nu_{O_2stoich}}\,100 = \frac{22.101}{9.6 + \frac{1}{4} \times 29.804}\ 100 = \mathbf{149.3\%}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.150

In an engine liquid octane and ethanol, mole ration 9:1, and stoichiometric air are taken in at 298 K, 100 kPa. After complete combustion, the products run out of the exhaust system where they are cooled to 10°C. Find the dew point of the products and the mass of water condensed per kilogram of fuel mixture.

Reaction equation with 0.9 octane and 0.1 ethanol is

$$0.9\ C_8H_{18} + 0.1\ C_2H_5OH + 11.55\ O_2 + 43.428\ N_2 \rightarrow 8.4\ H_2O + 7.4\ CO_2 + 43.428\ N_2$$

$$y_{H_2O} = \frac{8.4}{8.4 + 7.4 + 43.428} = 0.1418$$

$$P_{H_2O} = y_{H_2O} P_{tot} = \mathbf{14.3\ kPa} \quad \Rightarrow \quad T_{dew} = \mathbf{52.9\ °C}$$

$$10\ °C \Rightarrow P_{H_2O} = 1.2276 \quad \Rightarrow \quad y_{H_2O} = 0.012276 = \frac{x}{x + 7.4 + 43.428}$$

$$\Rightarrow x = \mathbf{0.6317} \quad \Rightarrow \quad \Delta\nu_{H_2O} = -7.77 \frac{\text{kmol}}{\text{kmol Fu mix}}$$

$$M_{mix} = \sum y_i M_i = 0.9 \times 114.23 + 0.1 \times 46.069 = 107.414$$

$$m_{H_2O\ cond} = \frac{-\Delta\nu_{H_2O} \times 18.015}{107.414} = \mathbf{1.303} \frac{\mathbf{kg}}{\mathbf{kg\ Fu\ mix}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.151

Find the lower heating value for the fuel blend in problem 15.134 with a scaling as in Table 13.3

Reaction equation with 0.9 octane and 0.1 ethanol is

$$0.9\ C_8H_{18} + 0.1\ C_2H_5OH + 11.55\ O_2 + 43.428\ N_2 \rightarrow 8.4\ H_2O + 7.4\ CO_2 + 43.428\ N_2$$

We can solve several ways, use Table A.10 to find $\overset{\circ}{H}_{RP}$ and do it on a mole basis and then divide with M for mixture or we can convert the mole fractions to mass fractions and use Table 13.3 values. Let us use Table 13.3.

$$M_{mix} = \sum y_i M_i = 0.9 \times 114.23 + 0.1 \times 46.069 = 107.414$$

$$c_{ethanol} = yM/M_{mix} = \frac{0.1 \times 46.069}{107.414} = 0.042889, \quad c_{octane} = 0.957111$$

$$LHV = c_{ethanol}\, LHV_{ethanol} + c_{octane}\, LHV_{octane}$$
$$= 0.042889\ (26\ 811) + 0.957111\ (44\ 425) \quad kJ/kg$$
$$= \mathbf{43\ 670\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.152

Determine the higher heating value of the sample Wyoming coal as specified in Problem 13.148.

The higher heating value is for liquid water in the products. We need the composition of the products.

Converting from mass analysis:

Substance	S	H_2	C	O_2	N_2
c/M =	0.5/32	3.5/2	4.86/12	12/32	0.7/28
kmol / 100 kg coal	0.0156	1.75	4.05	0.375	0.025
Product	SO_2	H_2O	CO_2		

So the combustion equation becomes (for 100 kg coal)

$$\text{Fuel + Air} \rightarrow 1.75\ H_2O + 4.05\ CO_2 + 0.0156\ SO_2$$

The formation enthalpies are from Table A.10. Therefore,

$$\bar{h}_{RP0} = H_P^o - H_R^o = 4.05(-393\ 522) + 1.75(-285\ 830) + 0.0156(-296\ 842)$$

$$= -2\ 098\ 597 \text{ kJ/100 kg coal}$$

So that HHV = **+20 986 kJ/kg coal**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.153

Ethene, C_2H_4, and propane, C_3H_8, in a 1:1 mole ratio as gases are burned with 120% theoretical air in a gas turbine. Fuel is added at 25°C, 1 MPa and the air comes from the atmosphere, 25°C, 100 kPa through a compressor to 1 MPa and mixed with the fuel. The turbine work is such that the exit temperature is 800 K with an exit pressure of 100 kPa. Find the mixture temperature before combustion, and also the work, assuming an adiabatic turbine.

$\phi = 1$: $C_2H_4 + C_3H_8 + 8\ O_2 + 30.08\ N_2 \rightarrow 5\ CO_2 + 6\ H_2O + 30.08\ N_2$

$\phi = 1.2$: $C_2H_4 + C_3H_8 + 9.6\ O_2 + 36.096\ N_2$

$\rightarrow 5\ CO_2 + 6\ H_2O + 1.6\ O_2 + 36.096\ N_2$

45.696 kmol air per 2 kmol fuel

C.V. Compressor (air flow)

Energy Eq.: $w_c = h_2 - h_1$ Entropy Eq.: $s_2 = s_1 \Rightarrow$

$P_{r_2} = P_{r_1} \times P_2/P_1 = 13.573 \Rightarrow T_{2\ air} =$ **570.8 K**

$w_c = 576.44 - 298.34 =$ **278.1 kJ/kg = 8056.6 kJ/kmol air**

C.V. Mixing Chanber (no change in composition)

$$\dot{n}_{air}\bar{h}_{air\ in} + \dot{n}_{Fu1}\bar{h}_{1\ in} + \dot{n}_{Fu2}\bar{h}_{2\ in} = (\text{SAME})_{exit}$$

$$\left(\bar{C}_{P\ F1} + \bar{C}_{P\ F2}\right)\left(T_{exit} - T_0\right) = 45.696\ \bar{C}_{P\ air}\left(T_{2\ air} - T_{exit}\right)$$

C_2H_4: $\bar{C}_{P\ F1} = 43.43$, C_3H_8: $\bar{C}_{P\ F2} = 74.06$, $\bar{C}_{P\ air} = 29.07$

$$T_{exit} = \frac{45.696\bar{C}_{P\ air}T_2 + (43.43 + 74.06)\ T_0}{43.43 + 74.06 + 45.696\ \bar{C}_{P\ air}} =$$ **548.7 K**

Dew Point Products: $y_{H_2O} = \frac{6}{5 + 6 + 1.6 + 36.096} = 0.1232$

$P_{H_2O} = y_{H_2O}P_{tot} = 123.2$ kPa $\Rightarrow T_{dew} =$ **105.5°C**

C.V. Turb. + combustor + mixer + compressor (no Q)

$w_{net} = H_{in} - H_{out} = H_R - H_{P\ 800}$ (800°K out so no liquid H_2O)

$=$ **2 576 541** $\frac{\text{kJ}}{\text{2 kmol Fu}}$

$w_T = w_{net} + w_{comp} =$ **2 944 695** $\frac{\text{kJ}}{\text{2 kmol Fu}}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.154

Phenol C_6H_5OH (M = 94.11 kg/kmol, Cp = 1.7 kJ/kg-K) is used in a combustion process being burned with stoichiometric air. The reactants are supplied at 1.2 MPa, the air at T_o and the phenol as liquid at 100°C. Enough heat transfer Q_1, takes place after the combustion so the products reach 1500 K. After the heat transfer the products are sent through a turbine where they expand to 120 kPa.

a) Find the heat transfer Q_1 [kJ/kmol fuel].
b) Find the enthalpy of formation of the fuel as vapor.
c) Find the specific turbine work output W [kJ/kmol fuel].

First do the combustion equation for Phenol C_6H_5OH

$$C_6H_5OH + \nu_{O_2} (O_2 + 3.76\, N_2) \rightarrow 6\, CO_2 + 3\, H_2O + 26.32\, N_2$$

O balance: $1 + 2\nu_{O_2} = 6 \times 2 + 3 = 15 \quad \Rightarrow \quad \nu_{O_2} = 7$

N_2 balance: $\nu_{N_2} = 3.76\ \nu_{O_2} = 3.76 \times 7 = 26.32$

Energy Eq.: $0 = Q_1 + H_{R1} - H_{P2} = Q_1 - H^\circ_{RP} + \Delta H_{R1} - \Delta H_{P2}$

Table 13.3: $H^\circ_{RP} = 94.11\ (-31\ 117) = -2\ 928\ 421$ kJ/kmol, (fuel as liquid)

$$\Delta H_{R1} = M\, Cp\, (T_1 - T_0) = 94.11 \times 1.7 \times (100 - 25) = 11\ 999 \text{ kJ/kmol}$$

Table A.9: $\Delta H_{P2} = 6\, \Delta\bar{h}_{CO2} + 3\, \Delta\bar{h}_{H2O} + 26.32\, \Delta\bar{h}_{N2}$

$$= 6 \times 61705 + 3 \times 481549 + 26.32 \times 38405 = 1\ 525\ 497 \text{ kJ/kmol}$$

$$Q_1 = H^\circ_{RP} - \Delta H_{R1} + \Delta H_{P2} = -2\ 928\ 421 - 11\ 999 + 1\ 525\ 497$$

$$= -1\ 414\ 923 \text{ kJ/kmol}$$

$$H^\circ_{RP} = 94.11\ (-31\ 774) = -2\ 990\ 251 = 6\, \bar{h}^\circ_{f\, CO_2} + 3\, \bar{h}^\circ_{f\, H_2O} - \bar{h}^\circ_{f\, fuel}$$

$$\bar{h}^\circ_{f\, fuel} = 3\, \bar{h}^\circ_{f\, H_2O} + 6\, \bar{h}^\circ_{f\, CO_2} - H^\circ_{RP}$$

$$= 3\,(-241\ 826) + 6(-393\ 522) - (-2\ 990\ 251) = \mathbf{-96\ 359 \text{ kJ/kmol}}$$

For W_T we need exit T and as product is mainly N_2 use air approximation (same k):

Constant C_P, k: $T_3 = T_2\, (P_3/P_2)^{\frac{k-1}{k}} = 1500\, (120/1200)^{0.2857} = 776.95$ K

Variable C_P, k: $P_{r3} = P_{r2}\, (P_3/P_2) = 483.16/10 = 48.316 \quad \Rightarrow \quad \mathbf{T_3 = 850\ K}$

See Table A.7.2 for this or use the standard entropy for this calculation

$$\Delta H_{P3} = 6 \times 25418 + 3 \times 19969.5 + 26.32 \times 16634.5 = 650\ 237 \text{ kJ/kmol}$$

$$W = \Delta H_{P2} - \Delta H_{P3} = 1\ 525\ 497 - 650\ 237 = \mathbf{875\ 260 \text{ kJ/kmol}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.155

The phenol in Problem 13.154 is used in a gasturbine cycle where we need the heating value (or the negative of the enthalpy of combustion at the temperature after the compressor).

a) What is the T after the compressor assuming a simple adiabatic compression from 100 kPa to 1.2 MPa?
b) Find the $H_{RP} = H_P - H_R$ both at that T except phenol is liquid at 100°C?

Assume the reactants are similar to air

Constant C_P, k: $T_2 = T_1 (P_2/P_1)^{\frac{k-1}{k}} = 298.15\ (1200/100)^{0.2857} = 606.4$ K

Variable C_P, k: $P_{r2} = P_{r1} (P_2/P_1) = 1.0907 \times 12 = 13.088 \quad \Rightarrow \quad \mathbf{T_3 = 600\ K}$

See Table A.7.2 for this or use the standard entropy for this calculation
First do the combustion equation for Phenol C_6H_5OH

$$C_6H_5OH + \nu_{O_2} (O_2 + 3.76\ N_2) \rightarrow 6\ CO_2 + 3\ H_2O + 26.32\ N_2$$

O balance: $1 + 2\nu_{O_2} = 6 \times 2 + 3 = 15 \quad \Rightarrow \quad \nu_{O_2} = 7$

N_2 balance: $\nu_{N_2} = 3.76\ \nu_{O_2} = 3.76 \times 7 = 26.32$

For enthalpy of fuel use $C_P \approx 1.7$ kJ/kgK similar to other fuels

$\Delta H_R = \Delta\bar{h}_{fuel} + 7(\Delta\bar{h}_{O2} + 3.76\Delta\bar{h}_{N2})$
$= 1.7 \times 94.11 \times (600 - 298.15) + 7(9245 + 3.76 \times 8894) = 347\ 097$ kJ/kmol
$\Delta H_P = 6 \times 12906 + 3 \times 10499 + 26.32 \times 8894 = 343\ 023$ kJ/kmol
$\overset{\circ}{H}_{RP} = 94.11\ (-31\ 774) = -2\ 990\ 251$

Gaseous fuel value at 298 K which is then a hypothetical state as the reference, so since the 600 K is higher than the 100°C then it does not matter.
Now we get

$$\overset{\circ}{H}_{RP} = \overset{\circ}{H}_{RP} + \Delta H_P - \Delta H_R = -2\ 990\ 251 + 343\ 023 - 347\ 097$$
$$= -2\ 994\ 325\ \text{kJ/kmol}$$

For a cycle calculation we would then use $q_H = \overset{\circ}{H}_{RP} / [94.11 \times (1 + AF)]$ in kJ/kg mix

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.156

Consider the gas mixture fed to the combustors in the integrated gasification combined cycle power plant, as described in Problem 13.30. If the adiabatic flame temperature should be limited to 1500 K, what percent theoretical air should be used in the combustors?

Product	CH_4	H_2	CO	CO_2	N_2	H_2O	H_2S	NH_3
% vol.	0.3	29.6	41.0	10.0	0.8	17.0	1.1	0.2

Mixture may be saturated with water so the gases are (H_2S and NH_3 out)

CH_4	H_2	CO	CO_2	N_2	n
0.3	29.6	41.0	10.0	0.8	81.7

$$y_{v\,max} = 7.384/3000 = n_v/(n_v + 81.7)$$

Solving, $n_v = 0.2$ kmol, the rest is condensed

$$\{0.3\,CH_4 + 29.6\,H_2 + 41.0\,CO + 10.0\,CO_2 + 0.8\,N_2$$
$$+ 0.2\,H_2O + 35.9x\,O_2 + 3.76 \times 35.9x\,N_2\} \rightarrow$$
$$51.3\,CO_2 + 30.4\,H_2O + 35.9(x - 1)\,O_2 + (135.0x + 0.8)\,N_2$$

For the fuel gas mixture at 40°C,

$$n\bar{C}_{P0\,mix} = 0.3 \times 16.04 \times 2.2537 + 29.6 \times 2.016 \times 14.2091$$
$$+ 41.0 \times 28.01 \times 1.0413 + 10.0 \times 44.01 \times 0.8418$$
$$+ 0.8 \times 28.013 \times 1.0416 + 0.2 \times 18.015 \times 1.8723 = 2455.157$$

$$n\bar{h}^0_{f\,mix} = 0.3(-74873) + 29.6(0) + 41.0(-110527)$$
$$+ 10.0(-393522) + 0.8(0) + 0.2(-241826) = -8537654\ kJ$$
$$H_{mix} = -8\,537\,654 + 2455.157(40 - 25) = -8\,500\,827\ kJ$$

Assume air enters at 25°C: $\bar{h}_{air} = 0$

Products at 1500 K:

$$H_p = 51.3(-393522 + 61705) + 30.4(-241826 + 48149)$$
$$+ 35.9(x - 1)(0 + 40600) + (135x + 0.8)(0 + 38405)$$
$$= -24\,336\,806 + 6\,642\,215x$$

Energy Eq.: $H_p = H_R = H_{mix}$

$$x = \frac{+24336809 - 8500827}{6642215} = 2.384 \quad \text{or} \quad \textbf{238 \% theo. air}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.157

Carbon monoxide, CO, is burned with 150% theoretical air and both gases are supplied at 150 kPa and 600 K. Find the heating value and the adiabatic flame temperature.

$$CO + \nu_{O_2}(O_2 + 3.76\, N_2) \rightarrow CO_2 + \nu_{N_2}\, N_2$$

O balance: $1 + 2\nu_{O_2} = 1 \quad \Rightarrow \quad \nu_{O_2} = 0.5 \quad \Rightarrow \nu_{O_2\ actual} = 0.75$

Now the actual reaction equation has excess oxygen as

$$CO + 0.75\,(O_2 + 3.76\, N_2) \rightarrow CO_2 + 2.82\, N_2 + 0.25\, O_2$$

From the definition of heating value (negative of enthalpy of combustion), Eq.13.14 or 13.15

$$HV = -H^{\circ}_{RP} = -(H^{\circ}_P - H^{\circ}_R) = -\bar{h}^{o}_{f\,CO_2} - 0 + \bar{h}^{o}_{f\,CO}$$

$$= -(-393\,522) + (-110\,527) = \mathbf{282\,995\ kJ/kmol\ CO}$$

$$= \mathbf{10\,103\ kJ/kg\ CO} \qquad \text{(as for Table 13.3)}$$

Actual energy Eq.: $H_R = H_P = H^{\circ}_P + \Delta H_P = H^{\circ}_R + \Delta H_R$

$$\Delta H_P = H^{\circ}_R + \Delta H_R - H^{\circ}_P = -H^{\circ}_{RP} + \Delta\bar{h}_{CO} + 0.75\,\Delta\bar{h}_{O_2} + 2.82\,\Delta\bar{h}_{N_2}$$

$$= HV + \Delta\bar{h}_{CO} + 0.75\,\Delta\bar{h}_{O_2} + 2.82\,\Delta\bar{h}_{N_2}$$

$$= 282\,995 + 8942 + 0.75 \times 9245 + 2.82 \times 8894$$

$$= 323\,952\ kJ/kmol$$

The left hand side is

$$\Delta H_P = \Delta\bar{h}_{CO_2} + 0.25\,\Delta\bar{h}_{O_2} + 2.82\,\Delta\bar{h}_{N_2}$$

$$\Delta H_{P\ 2600} = 128\,074 + 0.25 \times 82\,225 + 2.82 \times 77\,963 = 368\,486$$

$$\Delta H_{P\ 2400} = 115\,779 + 0.25 \times 74\,453 + 2.82 \times 70\,640 = 333\,597$$

$$\Delta H_{P\ 2200} = 103\,562 + 0.25 \times 66\,770 + 2.82 \times 63\,362 = 298\,935$$

Now we can do a linear interpolation for the adiabatic flame temperature

$$T = 2200 + 200\,\frac{323\,952 - 298\,935}{333\,597 - 298\,935} = \mathbf{2344\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.158

A rigid container is charged with butene, C_4H_8, and air in a stoichiometric ratio at P_0, T_0. The charge burns in a short time with no heat transfer to state 2. The products then cool with time to 1200 K, state 3. Find the final pressure, P_3, the total heat transfer, ${}_1Q_3$, and the temperature immediately after combustion, T_2.

The reaction equation is, having used C and H atom balances:

$$C_4H_8 + \nu_{O_2}(O_2 + 3.76\ N_2) \rightarrow 4\ CO_2 + 4\ H_2O + 3.76\ \nu_{O_2} N_2$$

Counting now the oxygen atoms we require $\nu_{O_2} = 6$.

C.V. analysis gives:

$$U_3 - U_1 = Q - W = Q = H_3 - H_1 - P_2V_2 + P_1V_1 = H_3 - H_1 - \bar{R}(n_2T_3 - n_1T_1)$$

$$H_3 - H_1 = H_{P\ 1200} - H_R^\circ = H_P^\circ - H_R^\circ + \Delta H_P = \hat{M}\ H_{RP}^\circ + \Delta H_P$$

$$= 56.108 \times (-45\ 316) + 950055 = -1\ 592\ 535\ \text{kJ/kmol}$$

Where $\hat{M} = 56.108$ and $n_1 = 1 + 6 \times 4.76 = 29.56$, $n_2 = 4 + 4 + 6 \times 3.76 = 30.56$,

Table A.9 at 1200 K: $\Delta h_{CO_2} = 44473$, $\Delta h_{H_2O} = 34506$, $\Delta h_{N_2} = 28109$.

Now solving for the heat transfer:

$$Q = -1592535 - 8.3145(30.56 \times 1200 - 29.56 \times 298.15) = -1824164\ \frac{\text{kJ}}{\text{kmol fuel}}$$

To get the pressure, assume ideal gases:

$$P_3 = \frac{n_2\bar{R}T_3}{V_2} = P_1 \frac{n_2T_3}{n_1T_1} = 101.325\ \text{kPa} \times \frac{30.56 \times 1200}{29.56 \times 298.15} = 421.6\ \text{kPa}$$

Before heat transfer takes place we have constant U so:

$$U_2 - U_1 = 0 = H_2 - H_1 - n_2\bar{R}T_2 + n_1\bar{R}T_1$$

Now split the enthalpy $H_2 = H_P^\circ + \Delta H_P(T_2)$ and arrange things with the unknowns on LHS and knowns on RHS:

$$\Delta H_P - n_2\bar{R}T_2 = H_R - H_P^\circ - n_1\bar{R}T_1 = 2\ 542\ 590 - 73278 = 2\ 469\ 312$$

Trial and error leads to:

LHS (3000 K) = $3\ 209\ 254 - 30.56 \times 8.31451 \times 3000 = 2\ 446\ 980$

LHS (3200 K) = $3\ 471\ 331 - 30.56 \times 8.31451 \times 3200 = 2\ 658\ 238$

linear interpolation T = **3021 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.159

Natural gas (approximate it as methane) at a ratio of 0.3 kg/s is burned with 250% theoretical air in a combustor at 1 MPa where the reactants are supplied at T_0. Steam at 1 MPa, 450°C at a rate of 2.5 kg/s is added to the products before they enter an adiabatic turbine with an exhaust pressure of 150 kPa. Determine the turbine inlet temperature and the turbine work assuming the turbine is reversible.

$$CH_4 + \nu_{O_2}(O_2 + 3.76\, N_2) \rightarrow CO_2 + 2\, H_2O + 7.52\, N_2$$

$$2\,\nu_{O_2} = 2 + 2 \;\Rightarrow\; \nu_{O_2} = 2 \quad => \quad \text{Actual } \nu_{O_2} = 2 \times 2.5 = 5$$

$$CH_4 + 5\, O_2 + 18.8\, N_2 \rightarrow CO_2 + 2\, H_2O + 3\, O_2 + 18.8\, N_2$$

C.V. combustor and mixing chamber

$$H_R + n_{H_2O}\bar{h}_{H_2O\ in} = H_{P\ ex}$$

$$n_{H_2O} = \frac{\dot{n}_{H_2O}}{\dot{n}_{Fu}} = \frac{\dot{m}_{H_2O}M_{Fu}}{\dot{m}_{Fu}M_{H_2O}} = \frac{2.5 \times 16.043}{0.3 \times 18.015} = 7.421\ \frac{\text{kmol steam}}{\text{kmol fuel}}$$

Energy equation becomes

$$n_{H_2O}\left(\bar{h}_{ex} - \bar{h}_{in}\right)_{H_2O} + \left(\Delta\bar{h}_{CO_2} + 2\Delta\bar{h}_{H_2O} + 3\Delta\bar{h}_{O_2} + 18.8\Delta\bar{h}_{N_2}\right)_{ex}$$

$$= -\overset{\circ}{H}_{RP} = 50\ 010 \times 16.043 = 802\ 310$$

$\left(\bar{h}_{ex} - \bar{h}_{in}\right)_{H_2O} = \Delta\bar{h}_{H_2O\ ex} - 15072.5$, so then:

$$\left(\Delta\bar{h}_{CO_2} + 9.421\Delta\bar{h}_{H_2O} + 3\Delta\bar{h}_{O_2} + 18.8\Delta\bar{h}_{N_2}\right)_{ex} = 914\ 163\ \frac{\text{kJ}}{\text{kmol fuel}}$$

Trial and error on T_{ex}

$T_{ex} = 1000$ K $\Rightarrow$ LHS = 749 956 ; $T_{ex} = 1100$ K $\Rightarrow$ LHS = 867429

$T_{ex} = 1200$ K $\Rightarrow$ LHS = 987 286 $\Rightarrow$ $T_{ex} \cong$ **1139 K = $T_{in\ turbine}$**

If air then $T_{ex\ turbine} \approx 700$ K and $T_{avg} \approx 920$ K. Find $\bar{C}_{P\ mix}$ between 900 and 1000 K. From Table A.9:

$$\bar{C}_{P\ mix} = \sum n_i \bar{C}_{P_i} / \sum n_i = \frac{53.67 + 9.421(40.63) + 3(34.62) + 18.8(32.4)}{32.221}$$

$$= 35.673\ \text{kJ/kmol K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$\bar{C}_{V\,mix} = \bar{C}_{P\,mix} - \bar{R} = 27.3587$ kJ/kmol, $k_{mix} = 1.304$

$T_{ex\,turbine} = 1139\,(150 / 1000)^{0.2331} = 732$ K

$\Delta H_{732} = 19370.6 + 9.421(15410) + 3(13567) + 18.8(12932)$

$= 448\,371$ kJ/kmol

$w_T = H_{in} - H_{ex} = \Delta H_{in} - \Delta H_{ex} = 914\,163 - 448\,371 = 465\,792 \frac{\text{kJ}}{\text{kmol fuel}}$

$\dot{W}_T = \dot{n}_{Fu} w_T = \dot{m}_{Fu} w_T / \hat{M}_{Fu} = (0.3 \times 465\,792)16.043 =$ **8710 kW**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.160

The turbine in Problem 13.153 is adiabatic. Is it reversible, irreversible, or impossible?

Inlet to the turbine is the exit from the mixing of air and fuel at 1 MPa. From solution to 13.153, we have:

$$\bar{C}_{P\,C_2H_2} = 43.43, \quad \bar{C}_{P\,C_3H_8} = 74.06, \quad T_{turbine,in} = 548.7\ K$$

$$C_2H_4 + C_3H_8 + 9.6\ O_2 + 36.096\ N_2$$

$$\rightarrow 5\ CO_2 + 6\ H_2O + 1.6\ O_2 + 36.096\ N_2$$

$$S_{ex} - S_{in} = \int dQ/T + S_{gen} = S_{gen} \geq \phi$$

Inlet: 1 MPa, 548.7 K $\qquad \bar{S}_{Fu} = \bar{S}_i^{\circ} + \bar{C}_{P\,Fu} \ln\left(T/T_0\right)$

	n_i	y_i	$\bar{s}_i^{\circ}$	$-\bar{R}\ln\frac{y_iP}{P_0}$	$\bar{S}_i$
C_2H_4	1	0.02097	245.82	12.989	258.809
C_3H_8	1	0.02097	315.09	12.989	328.079
O_2	9.6	0.2013	223.497	-5.816	217.681
N_2	36.096	0.7568	209.388	-16.828	192.56

$$S_{in} = 258.809 + 328.079 + 9.6 \times 217.681 + 36.096 \times 192.56 = 9627.3$$

	n_i	y_i	$\bar{s}_i^{\circ}$	$-\bar{R}\ln\frac{y_iP}{P_0}$	S_i
CO_2	5	0.1027	257.496	18.925	276.421
H_2O	6	0.1232	223.826	17.409	241.235
O_2	1.6	0.0329	235.92	28.399	264.319
N_2	36.096	0.7413	221.016	2.489	223.505

$$S_{ex} = 5 \times 276.421 + 6 \times 241.235\ 1.6 \times 264.319$$

$$+ 36.096 \times 223.505 = 11320\ \frac{kJ}{2kmol\ Fu\ K}$$

$$S_{gen} = S_{ex} - S_{in} = \mathbf{1693\ \frac{kJ}{2kmol\ Fu\ K} > 0}$$

Possible, but one should check the state after combustion to account for generation by combustion alone and then the turbine expansion separately.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.161

Consider the combustion process described in Problem 13.119.

a. Calculate the absolute entropy of the fuel mixture before it is throttled into the combustion chamber.

b. Calculate the irreversibility for the overall process.

From solution to 13.119, fuel mixture $0.8\ C_2H_6 + 0.2\ CH_4$ at 65°C, 10 MPa

$\bar{C}_{P0\ FUEL}$ = 49.718 kJ/kmol K. Using Kay's rule: T_{r1} = 1.198, P_{r1} = 2.073

and x = 410.4 % theoretical air

or $13.13\ O_2 + 49.36\ N_2$ in at 600 K, 100 kPa

and $1.8CO_2 + 2.8H_2O + 9.93O_2 + 49.36N_2$ out at 100 kPa, 1200 K

$\bar{s}^*_{0\ FUEL} = 0.2(186.251) + 0.8(229.597) - 8.3145(0.2 \ln 0.2 + 0.8 \ln 0.8) = 225.088$

$$\Delta s^*_{TP} = 49.718 \ln \frac{338.2}{298.2} - 8.3145 \ln \frac{10}{0.1} = -32.031$$

From Fig. D.3: $(\bar{s}^* - \bar{s})_{FUEL} = 1.37 \times 8.3145 = 11.391$

$\bar{s}_{FUEL}$ = 225.088 - 32.031 - 11.391 = **181.66 kJ/kmol K**

Air at 600 K, 100 kPa

	n_i	y_i	$\bar{s}^\circ_i$	$-\bar{R}\ln(y_iP/P_0)$	S_i
O_2	13.13	0.21	226.45	+12.976	239.426
N_2	49.36	0.79	212.177	+1.96	214.137

$S_{AIR} = \sum n_i \bar{S}_i$ = 13713.47 kJ/K

S_R = 181.66 + 13713.47 = 13895.1 kJ/K

Products at 1200 K, 100 kPa

PROD	n_i	y_i	$\bar{s}^o_i$	$-\bar{R}\ln(y_iP/P_0)$	S_i
CO_2	1.8	0.0282	279.390	+29.669	309.059
H_2O	2.8	0.0438	240.485	+26.008	266.493
O_2	9.93	0.1554	250.011	+15.479	265.490
N_2	49.36	0.7726	234.227	+2.145	236.372

$S_P = \sum n_i \bar{S}_i$ = 15606.1 kJ/K

$I = T_0(S_P - S_R) - Q_{CV}$ = 298.15(15 606.1 – 13 895.1) + 0 = **510 132 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.162

Liquid acetylene, C_2H_2, is stored in a high-pressure storage tank at ambient temperature, 25°C. The liquid is fed to an insulated combustor/steam boiler at the steady rate of 1 kg/s, along with 140% theoretical oxygen, O_2, which enters at 500 K, as shown in Fig. P13.162. The combustion products exit the unit at 500 kPa, 350 K. Liquid water enters the boiler at 10°C, at the rate of 15 kg/s, and superheated steam exits at 200 kPa.

a. Calculate the absolute entropy, per kmol, of liquid acetylene at the storage tank state.

b. Determine the phase(s) of the combustion products exiting the combustor boiler unit, and the amount of each, if more than one.

c. Determine the temperature of the steam at the boiler exit.

a) C_2H_2: $\bar{S}^\circ_{IG\ 25°C} = 200.958$ kJ/kmol-K from A.10

$T_{R_1} = 298.2/308.3 = 0.967$ => From Fig. D.1: $P_{R_1} = 0.82$

$P_1 = 0.82 \times 6.14 = 5.03$ MPa, $\left(\bar{S}^* - \bar{S}\right)_1 = 3.33\bar{R} = 27.687$ kJ/kmolK

$$\bar{S}_{liq\ T_1 P_1} = \bar{S}^\circ_{T_0 P_0} + \Delta T - \bar{R} \ln\left(P_1/P^\circ\right) + \left(\bar{S} - \bar{S}^*\right)_{P_1 T_1} = \mathbf{140.695\ \frac{kJ}{kmol\ K}}$$

b) $1\ C_2H_2 + 1.4 \times 2.5\ O_2 \rightarrow 2\ CO_2 + 1\ H_2O + 1\ O_2$

$H_1 = 226731 + (-3.56 \times \bar{R} \times 308.3) = 217605$ kJ;

$H_2 = 3.5(0 + 6086) = 21301$ kJ

Products $T_3 = 350$ K = 76.8°C $\Rightarrow$ $P_G = 41.8$ kPa

$$y_{V\ max} = \frac{P_G}{P} = \frac{41.8}{500} = 0.0836 = \frac{n_{V\ max}}{n_{V\ max} + 2 + 1} \Rightarrow n_{V\ max} = 0.2737 = n_{V\ gas\ mix}$$

$\Rightarrow n_{liq} = 1 - 0.2737 = \mathbf{0.7263}$

Gas Mix = $\mathbf{2\ CO_2 + 0.2737\ H_2O + 1\ O_2}$

c) $H_{liq3} = 0.7263(-285830 + 18.015(321.5 - 104.9)) = -204764$ kJ

$H_{gas\ mix3} = 2(-393522 + 2036) + 0.2737(-241826 + 1756) + 1541 = -847138$ kJ

$H_3 = H_{liq3} + H_{gas\ mix3} = -204\,764 - 847\,138 = -1\,051\,902$ kJ

$H_3 - H_1 - H_2 = -1\,290\,808$ kJ

or $\dot{H}_3 - \dot{H}_1 - \dot{H}_2 = -1\,290\,808/26.038 = -49\,574$ kW $= \dot{m}_{H_2O}\left(h_4 - h_5\right)$

$$h_5 = 42.01 + \frac{49574}{15} = 3346.9 \quad \Rightarrow \quad T_5 = \mathbf{433.4°C}$$

13.163E

The output gas mixture of a certain air-blown coal gasifier has the composition of producer gas as listed in Table 13.2. Consider the combustion of this gas with 120% theoretical air at 14.7 lbf/in.^{2} pressure. Find the dew point of the products and the mass of water condensed per pound-mass of fuel if the products are cooled 20 F below the dew point temperature?

$$\{3\,CH_4 + 14\,H_2 + 50.9\,N_2 + 0.6\,O_2 + 27\,CO + 4.5\,CO_2\}$$
$$+ 31.1\,O_2 + 116.9\,N_2 \rightarrow 34.5\,CO_2 + 20\,H_2O + 5.2\,O_2 + 167.8\,N_2$$

Products:

$$y_{H2O} = y_{H2O\,MAX} = \frac{P_G}{14.7} = \frac{20}{34.5 + 20 + 5.2 + 167.8}$$

$$\Rightarrow P_G = 1.2923 \text{ lbf/in}^2 \rightarrow T_{DEW\,PT} = \mathbf{110.4\ F}$$

At T = 90.4 F, $P_G = 0.7089$ lbf/in^2

$$y_{H2O\,max} = \frac{0.7089}{14.7} = \frac{n_{H2O}}{n_{H2O} + 34.5 + 5.2 + 167.8} \quad \Rightarrow \quad n_{H2O} = 10.51$$

$$\Rightarrow n_{H2O\,LIQ} = 20 - 10.51 = 9.49 \text{ lb mol}$$

$$m_{H2O\,LIQ} = \frac{9.49(18)}{3(16)+14(2)+50.9(28)+0.6(32)+27(28)+4.5(44)}$$

$$= \mathbf{0.069\ lbm/lbm\ fuel}$$

13.164E

What is the enthalpy of formation for oxygen as O_2? If O? For CO_2?

From Table F.6

$\bar{h}^\circ_{f\,O2} = 0$

$\bar{h}^\circ_{f\,O} = 107\,124$ Btu/lbmol

$\bar{h}^\circ_{f\,CO2} = -169\,184$ Btu/lbmol (or Table F.11)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.165E

One alternative to using petroleum or natural gas as fuels is ethanol (C_2H_5OH), which is commonly produced from grain by fermentation. Consider a combustion process in which liquid ethanol is burned with 110% theoretical air in a steady flow process. The reactants enter the combustion chamber at 77 F, and the products exit at 140 F, 14.7 lbf/in.^{2}. Calculate the heat transfer per lbmol fuel.

$$C_2H_5OH + 1.1 \times 3\,(O_2 + 3.76\,N_2) \rightarrow 2CO_2 + 3H_2O + 0.3O_2 + 12.408N_2$$

Products at 140 F, 14.7 lbf/in^2, Psat = 2.892 psia

$y_{H2O} = 2.892/14.7 = n_v/(2 + 0.3 + n_v + 12.408)$

$n_v = 3.6023 > 3 \quad \Rightarrow \quad$ no condensation

$\bar{h}^\circ_f$ = -119 252 Btu/lbmol as liquid from F.11

H_R = -119 252 + 0 + 0 = -119 252 Btu/ lbmol fuel

$H_P = 2(-169184 + 570) + 3(-47518 + 506.5)$

$+ 0.3(0 + 443.7) + 12.408(0 + 438.4) = -472\,690$ Btu/ lbmol fuel

$Q_{CV} = H_P - H_R =$ **-353 438 Btu/lbmol fuel**

An ethanol flame

13.166E

Liquid methanol is burned with stoichiometric air both supplied at P_o, T_o in a constant pressure process and the products exits a heat exchanger at 1600 R. Find the heat transfer per lbmol fuel

$$CH_3OH + 1.5\,(O_2 + 3.76\,N_2) \rightarrow 1\,CO_2 + 2\,H_2O + 5.64\,N_2$$

Reactants at 77 F, products are at 1600 R, 14.7 psia.

CH_3OH: $\bar{h}_f^o$ = –102 846 Btu/lbmol from table F.11 for the liquid state

$H_R = 1\,\bar{h}_{LIQ} + 0 + 0$ = –102 846 Btu/lbmol fuel

$H_P = 1(–169\,184 + 11\,798) + 2(–103\,966 + 9241) + 5.64(0 + 7681)$

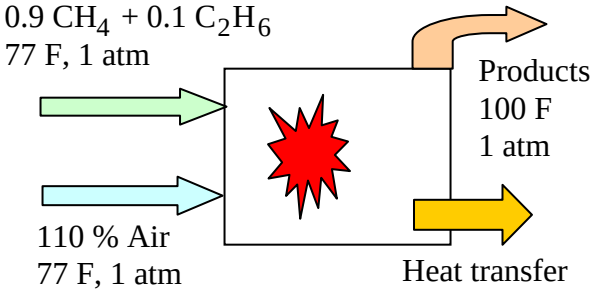
= –303 515 Btu/lbmol fuel

$Q = H_P - H_R$ = –303 515 – (–102 846) = **–200 669 Btu/lbmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.167E

In a new high-efficiency furnace, natural gas, assumed to be 90% methane and 10% ethane (by volume) and 110% theoretical air each enter at 77 F, 14.7 lbf/in.^{2}, and the products (assumed to be 100% gaseous) exit the furnace at 100 F, 14.7 lbf/in.^{2}. What is the heat transfer for this process? Compare this to an older furnace where the products exit at 450 F, 14.7 lbf/in.^{2}.



$$0.9\,CH_4 + 0.1\,C_2H_6 + 1.1 \times 2.15\,O_2 + 3.76 \times 2.365\,N_2$$
$$\rightarrow 1.1\,CO_2 + 2.1\,H_2O + 0.215\,O_2 + 8.892\,N_2$$

a) $T_P = 100$ F

$H_R = 0.9(-32190) + 0.1(-36432) = -32614$ Btu

$H_P = 1.1(-169184 + 206) + 2.1(-103966 + 185)$
$+ 0.215(0 + 162) + 8.892(0 + 160) = -402\,360$ Btu/lbmol,

assuming all gas

$Q_{CV} = H_P - H_R =$ **-369 746 Btu/lb mol fuel**

b) $T_P = 450$ F

$H_P = 1.1(-169184 + 3674) + 2.1(-103966 + 3057)$
$+ 0.215(2688) + 8.892(2610) = -370\,184$ Btu

$Q_{CV} = H_P - H_R =$ **-337 570 Btu/lb mol fuel**

13.168E

Repeat the previous problem, but take into account the actual phase behavior of the products exiting the furnace.

Same as 13.167 , except possible condensation.

$$0.9\,CH_4 + 0.1\,C_2H_6 + 1.1 \times 2.15\,O_2 + 3.76 \times 2.365\,N_2$$
$$\rightarrow 1.1\,CO_2 + 2.1\,H_2O + 0.215\,O_2 + 8.892\,N_2$$

a) 100 F, 14.7 lbf/in^2 Psat = 0.95 psia

$y_{v\,max} = 0.95 / 14.7 = n_{v\,max}/[n_{v\,max} + 10.207]$

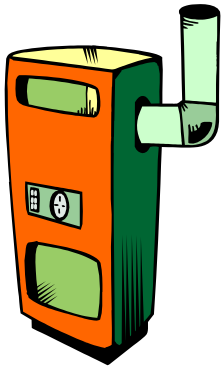
$n_{v\,max} = 0.705 \Rightarrow \quad n_v = 0.705; \qquad n_{liq} = 2.1 - 0.705 = 1.395$

$H_{liq} = 1.395[-122\,885 + 18.015(68.05 - 45.09)] = -170\,847$ Btu/lbmol

$H_{gas} = 1.1(-169\,184 + 206) + 0.705(-103\,966 + 185)$
$+ 0.215(162) + 8.892(160) = -257\,584$ Btu/lbmol

$H_P = H_{liq} + H_{gas} = -428\,431$ Btu/lbmol

$Q_{CV} = H_P - H_R =$ **-395817 Btu/lbmol fuel**



b) T_P = 450 F, no condensation

$H_P = 1.1(-169\,184 + 3674) + 2.1(-103\,966 + 3057)$
$+ 0.215(2688) + 8.892(2610)$
$= -370\,184$ Btu/lbmol

$Q_{CV} = H_P - H_R =$ **-337 570 Btu/lbmol fuel**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.169E

Pentene, C_5H_{10} is burned with pure oxygen in a steady state process. The products at one point are brought to 1300 R and used in a heat exchanger, where they are cooled to 77 F. Find the specific heat transfer in the heat exchanger.

$$C_5H_{10} + \nu_{O_2} O_2 \rightarrow 5\ CO_2 + 5\ H_2O, \quad \text{stoichiometric: } \nu_{O_2} = 7.5$$

Heat exchanger in at 1300 R, out at 77 F, so some water will condense.

$$5\ H_2O \rightarrow (5 - x) H_2O_{liq} + x\ H_2O_{vap}$$

Check for condensation amount

$$y_{H_2O_{max}} = \frac{P_{g\ 77}}{P_{tot}} = \frac{0.464}{14.696} = 0.03158 = \frac{x}{5 + x} \qquad \Rightarrow \quad x = 0.163$$

$$q = \frac{\dot{Q}}{\dot{n}_{fuel}} = 5\left(\bar{h}_{ex} - \bar{h}_{in}\right)_{CO_2} + 5\left(\bar{h}_{ex} - \bar{h}_{in}\right)_{H_2O_{vap}} - (5 - x)\bar{h}_{fg\ H_2O}$$

$$= 5\ (-8121) + 5\ (-6468.5) - (5 - 0.163)\ 18919$$

$$= \mathbf{-164\ 459}\ \frac{\mathbf{Btu}}{\mathbf{lb\ mol\ fuel}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.170E

Methane, CH_4, is burned in a steady state process with two different oxidizers: **A**. Pure oxygen, O_2 and **B** a mixture of $O_2 + x$ Ar. The reactants are supplied at T_0, P_0 and the products in are at 3200 R both cases. Find the required equivalence ratio in case **A** and the amount of Argon, *x*, for a stoichiometric ratio in case **B**.

a) $CH_4 + \nu O_2 \rightarrow CO_2 + 2H_2O + (\nu - 2)O_2$

$\nu_s = 2$ for stoichiometric mixture.

$H_{P\ 3200} = H_R^\circ = H_P^\circ + \Delta H_{P\ 3200}$

$\Delta \bar{h}_{CO2} = 33\ 579$ Btu/lbmol, $\Delta \bar{h}_{H2O} = 26\ 479$, $\Delta \bar{h}_{O2} = 21\ 860$

$\Delta H_P = H_R^\circ - H_P^\circ = -H_{RP}^\circ = (50\ 010/2.326) \times 16.04 = 344\ 867$ Btu/lbmol

$= 33\ 579 + 2 \times 26\ 479 + (\nu - 2)21\ 860 = 42\ 817 + \nu \times 21\ 860$

$\nu = 13.8175 \quad \Rightarrow \quad \phi = \nu_s/\nu = 2/13.8175 =$ **0.1447**

b) $CH_4 + 2O_2 + 2x\ Ar \rightarrow CO_2 + 2H_2O + 2x\ Ar$

$\Delta \bar{h}_{Ar} = \bar{C}_{P\ Ar}\, \Delta T = C_{P\ Ar}\, M_{Ar}\, \Delta T$

$\Delta H_P = H_R^\circ - H_P^\circ = -H_{RP}^\circ = (50\ 010/2.326) \times 16.04 = 344\ 867$ Btu/lbmol

$= 33579 + 2 \times 26479 + 2 \times 0.1253 \times 39.948 \times (3200 - 536.67)$

Now the energy equation becomes

$344\ 867 = 86537 + x \times 26662.5 \quad \Rightarrow$ **x = 9.689**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.171E

A rigid vessel initially contains 2 pound mole of carbon and 2 pound mole of oxygen at 77 F, 30 lbf/in.^{2}. Combustion occurs, and the resulting products consist of 1 pound mole of carbon dioxide, 1 pound mole of carbon monoxide, and excess oxygen at a temperature of 1800 R. Determine the final pressure in the vessel and the heat transfer from the vessel during the process.

$$2\,C + 2\,O_2 \rightarrow 1\,CO_2 + 1\,CO + \frac{1}{2}O_2$$

V = constant, C: solid, $n_{1(GAS)} = 2$, $n_{2(GAS)} = 2.5$

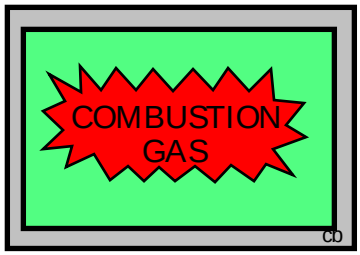
$$P_2 = P_1 \times \frac{n_2 T_2}{n_1 T_1} = 30 \times \frac{2.5 \times 1800}{2 \times 536.7} = \mathbf{125.8\ \frac{lbf}{in^2}}$$

$H_1 = 0$ and we neglect the Pv for carbon when doing the U_1.

$$H_2 = 1(-169184 + 14358) + 1(-47518 + 9323) + \tfrac{1}{2}(0 + 9761) = -188\,141 \text{ Btu}$$

$$_1Q_2 = (U_2 - U_1) = (H_2 - H_1) - n_2\bar{R}T_2 + n_1\bar{R}T_1$$

$$= (-188\,141 - 0) - 1.98589(2.5 \times 1800 - 2 \times 536.67) = \mathbf{-194\,945\ Btu}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.172E

A closed, insulated container is charged with a stoichiometric ratio of oxygen and hydrogen at 77 F and 20 lbf/in.^{2}. After combustion, liquid water at 77 F is sprayed in such that the final temperature is 2100 R. What is the final pressure?

Combustion reaction: $H_2 + \frac{1}{2}(O_2) \rightarrow H_2O$

Products: $1\ H_2O + x_i\ H_2O$

Energy eq. per 1 lbmol hydrogen (remember flow in):

$$U_2 - U_1 = x_i \bar{h}_i = x_i \bar{h}^\circ_{f\ liq} = (1 + x_i)H_P - H_R - (1 + x_i)\bar{R}T_P + \tfrac{3}{2}\bar{R}T_R$$

Solve for x_i: $x_i\ [\ \bar{h}^\circ_{f\ liq} - H_P + \bar{R}T_P\ ] = H_P - H_R - \bar{R}T_P + \frac{3}{2}\bar{R}T_R$

Table F.6: $H_R = \phi$, $H_P = -103\ 966 + 14\ 218.5 = -89\ 747.5$ Btu/lbmol,

Table F.11: $\bar{h}^\circ_{f\ liq} = -122\ 885$ Btu/lbmol

Substitute

$$x_i(-122885 + 89747.5 + 1.98588 \times 2100)$$

$$= -89747.5 - 1.98588(2100 - \tfrac{3}{2} \times 536.67) = -92\ 319.2 \text{ Btu/lbmol}$$

$$x_i = 3.187$$

Volume is constant: $P_1V_1 = n_R\bar{R}T_1$, $P_2V_1 = n_p\bar{R}T_p$

$n_R = 1 + \frac{1}{2} = 1.5$; $n_p = (1 + x_i)$

$$\Rightarrow P_2 = \frac{P_1(1 + x_i)T_P}{1.5\ T_1} = \frac{20(4.187)(2100)}{1.5(536.67)} = \mathbf{218.5\ lbf/in^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.173E

Acetylene gas, C_2H_2, is burned with stoichiometric air in a torch. The reactants are supplied at the reference conditions P_o, T_o. The products come out from the flame at 4500 R after some heat loss by radiation. Find the heat loss per lbmol of fuel.

The reaction equation is

$$C_2H_2 + 2.5\,(O_2 + 3.76\,N_2) \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$$

Energy Eq.: $H_P + Q_{out} = H_R = H_P^o + \Delta H_P + Q_{out} = H_R^o$

$$Q_{out} = H_R^o - H_P^o - \Delta H_P$$

$$H_R^o - H_P^o = \bar{h}^\circ_{f\,fuel} - \bar{h}^\circ_{f\,H_2O} - 2\,\bar{h}^\circ_{f\,CO_2} = 97\,477 - (-103\,966) - 2(-169\,184)$$
$$= 539\,811 \text{ Btu/lbmol}$$

$$\Delta H_P = 2 \times 52\,416.5 + 42\,612 + 9.4 \times 31\,942.5 = 447\,705 \text{ Btu/lbmol}$$

$$Q_{out} = 539\,811 - 447\,705 = \mathbf{92\,106 \text{ Btu/lbmol fuel}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.174E

Natural gas (methane) is burned with stoichiometric air with reactants supplied at the reference conditions Po, To in a steady flow burner. The products come out at 1400 R. If the burner should deliver 10 Btu/s, what is the needed flowrate of natural gas in lbm/s?

The reaction equation for stoichiometric mixture is:

$$CH_4 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 2\,H_2O + 1\,CO_2 + c\,N_2$$

O balance: $2\,\nu_{O2} = 2 + 2 \quad \Rightarrow \quad \nu_{O2} = 2 \quad \Rightarrow \quad c = 2 \times 3.76 = 7.52$

The products are cooled to 1400 R (so we do not consider condensation) and the energy equation is

Energy Eq.: $H_R + Q = H_P = H_P^\circ + \Delta H_P = H_R^\circ + Q$

$$Q = H_P^\circ + \Delta H_P - H_R^\circ = 2\,\bar{h}_{f\,H_2O}^\circ + \bar{h}_{f\,CO_2}^\circ + \Delta H_P - \bar{h}_{f\,fuel}^\circ$$

$$\Delta H_P = 2\,\Delta\bar{h}_{H2O} + \Delta\bar{h}_{CO2} + 7.52\,\Delta\bar{h}_{N2}$$

$$= 2 \times 7371 + 9315 + 7.52 \times 6169 = 70\,448 \text{ Btu/lbmol}$$

$$Q = 2(-103\,966) - 169\,184 + 70\,448 - (-32\,190)$$

$$= -274\,478 \text{ Btu/lbmol fuel}$$

$$\dot{Q} = \dot{n}\,Q_{out} = Q_{out}\,\dot{m}/M \qquad \text{so}$$

$$\dot{m} = \dot{Q}M/Q_{out} = 10 \text{ Btu/s} \times 16.043 \text{ (lbm/lbmol)} / 274\,478 \text{ Btu/lbmol}$$

$$= \mathbf{0.000584\ lbm/s} = 2.1 \text{ lbm/h}$$

Enthalpy of combustion and heating value

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.175E

What is the higher heating value, HHV, of n-Butane?

Either convert units from Table 13.3 or compute from the enthalpy of formation. From Table F.11

$\bar{h}^\circ_{f\ C4H10}$ = - 54 256 Btu/lbmol, M = 58.124

$\bar{h}^\circ_{f\ H2O\ liq}$ = -122 885 Btu/lbmol (we need liquid for higher heating value)

$\bar{h}^\circ_{f\ CO2}$ = -169 184 Btu/lbmol

$$HHV = -H^\circ_{RP} = \bar{h}^\circ_{f\ C4H10} - 4\,\bar{h}^\circ_{f\ CO2} - 5\,\bar{h}^\circ_{f\ H2O\ liq}$$

$$= -\ 54\ 256 - 4(-169\ 184) - 5(-122\ 885)$$

$$= \mathbf{1\ 236\ 905\ Btu/lbmol = 21\ 280\ Btu/lbm}$$

= 49 500 kJ/kg = 21 280 Btu/lbm (from Table 13.3)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.176E

Find the enthalpy of combustion and heating value for pure carbon.

Reaction: $C + \nu_{O_2}[\, O_2 + 3.76\, N_2\,] \rightarrow CO_2 + \nu_{O_2} 3.76\, N_2$

oxygen balance: $\nu_{O_2} = 1$

$$H^\circ_{RP} = H^o_P - H^o_R = \bar{h}^\circ_{f\,CO_2} - \bar{h}^\circ_{f\,C} = -169\,184 - 0$$

$$= \mathbf{-169\,184\ Btu/lbmol} = \mathbf{-14\,086\ Btu/lbm} \qquad (M = 12.011)$$

HV = 169 184 Btu/lbmol = **14 086 Btu/lbm**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.177E

Acetylene gas, C_2H_2, is burned with stoichiometric air in a torch. The reactants are supplied at the reference conditions P_o, T_o. The products come out from the flame at 5000 R after some heat loss by radiation. Find the lower heating value for the fuel, as it is not listed in Table 13.3, and the heat loss per kmol of fuel.

The reaction equation is

$$C_2H_2 + 2.5\,(O_2 + 3.76\,N_2) \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$$

Definition of the heating value and values from F.11

$$\begin{aligned} LHV = -H^{\circ}_{RP} &= H^{o}_{R} - H^{o}_{P} = \bar{h}^{\circ}_{f\,fuel} - \bar{h}^{\circ}_{f\,H_2O} - 2\,\bar{h}^{\circ}_{f\,CO_2} \\ &= 97\,477 - (-103\,966) - 2(-169\,184) \\ &= 539\,811 \text{ Btu/lbmol} = \mathbf{20\,731\ Btu/lbm} \end{aligned}$$

Energy Eq.: $H_P + Q_{out} = H_R = H^{o}_{P} + \Delta H_P + Q_{out} = H^{o}_{R}$

$$Q_{out} = H^{o}_{R} - H^{o}_{P} - \Delta H_P = LHV - \Delta H_P$$

$$\Delta H_P = 2 \times 59\,784 + 49\,114 + 9.4 \times 36\,330 = 510\,184 \text{ Btu/lbmol}$$

$$Q_{out} = 539\,811 - 510\,184 = \mathbf{29\,627\ Btu/lbmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.178E

Blast furnace gas in a steel mill is available at 500 F to be burned for the generation of steam. The composition of this gas is, on a volumetric basis,

Component	CH_4	H_2	CO	CO_2	N_2	H_2O
Percent by volume	0.1	2.4	23.3	14.4	56.4	3.4

Find the lower heating value (Btu/ft^3) of this gas at 500 F and P_0.

Of the six components in the gas mixture, only the first 3 contribute to the heating value. These are, per lb mol of mixture:

$$0.024\,H_2,\ 0.001\,CH_4,\ 0.233\,CO$$

For these components,

$$0.024\,H_2 + 0.001\,CH_4 + 0.233\,CO + 0.1305\,O_2 \rightarrow 0.026\,H_2 + 0.234\,CO_2$$

The remainder need not be included in the calculation, as the contributions to reactants and products cancel. For the lower HV(water vapor) at 500 F

$$\bar{h}_{RP} = 0.026(-103\,966 + 3488) + 0.234(-169\,184 + 4229) - 0.024(0 + 2101)$$
$$- 0.001(-32\,190 + 0.538 \times 16.04(500\text{-}77)) - 0.233(-47\,518 + 2981)$$
$$- 0.1305(0 + 3069) = -31\,257 \text{ Btu/lb mol fuel}$$

$$\bar{v}_0 = \frac{\bar{R}T_0}{P_0} = \frac{1545 \times 536.7}{14.7 \times 144} = 391.47 \text{ ft}^3\text{/lb mol}$$

LHV = 31 680 / 391.47 = **79.85 Btu/ft^3**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.179E

A burner receives a mixture of two fuels with mass fraction 40% n-butane and 60% methanol both vapor. The fuel is burned with stoichiometric air. Find the product composition and the lower heating value of this fuel mixture (Btu/lbm fuel mix).

Since the fuel mixture is specified on a mass basis we need to find the mole fractions for the combustion equation. From Eq.13.4 we get

$$y_{butane} = (0.4/58.124) / [0.4/58.124 + 0.6/32.042] = 0.26875$$

$$y_{methanol} = 1 - y_{butane} = 0.73125$$

The reaction equation is

$$0.73125\, CH_3OH + 0.26875\, C_4H_{10} + \nu_{O2}\,(O_2 + 3.76\, N_2)$$

$$\rightarrow \nu_{CO2}\, CO_2 + \nu_{H2O} H_2O + 3.76\, \nu_{O2}\, N_2$$

C balance: $0.73125 + 4 \times 0.26875 = \nu_{CO2} = 1.80625$

H_2 balance: $2 \times 0.73125 + 5 \times 0.26875 = \nu_{H2O} = 2.80625$

O balance: $0.73125 + 2\, \nu_{O2} = 2\, \nu_{CO2} + \nu_{H2O} = 6.41875 \Rightarrow \nu_{O2} = 2.84375$

Now the products are:

$$1.80625\, CO_2 + 2.80625\, H_2O + 10.6925\, N_2$$

Since the enthalpy of combustion is on a mass basis in table 13.3 (this is also the negative of the heating value) we get

$$LHV = (0.4 \times 45\,714 + 0.6 \times 21\,093)/2.326$$

$$= \mathbf{13\,302\ Btu/lbm\ fuel\ mixture}$$

Notice we took fuel vapor and water as vapor (lower heating value).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.180E

A mixture of fuels is E85, which is 85% ethanol and 15% gasoline (assume octane) by mass. Assume we put the fuel and air, both at T_o, P_o, into a carburetor and vaporize the fuel as we mix it with stoichiometric air before it flows to an engine. Assume the engine has an efficiency as work divided by the lower heating value of 30%, and we want it to deliver 55 hp. We use heat from the exhaust flow (900 R) for the carburetor. Find the lower heating value of this fuel (Btu/lbm), the rate of fuel consumption, the heating rate needed in the carburetor, and the rate of entropy generation in the carburetor.

The heating value of the liquid fuel blend (values from Tbl. 13.3 converted)

$$LHV = 0.85\, LHV_{ethanol} + 0.15\, LHV_{octane}$$
$$= (0.85 \times 26\,811 + 0.15 \times 44\,425)\, 0.42992 \text{ Btu/lbm} = \mathbf{12\,662 \text{ Btu/lbm}}$$

$$\dot{W} = 0.3\, \dot{m}_{fuel}\, LHV$$

$$\dot{m}_{fuel} = \dot{W}/(0.3 \times LHV) = 55 \text{ hp} \times 2544 \text{ Btu/h-hp} / (0.3 \times 12\,662 \text{ Btu/lbm})$$
$$= \mathbf{36.835 \text{ lbm/h} = 0.0102 \text{ lbm/s}}$$

The difference in heating value based on liquid versus vapor fuel is

$$\Delta LHV = [0.85\,(27\,731 - 26\,811) + 0.15\,(44\,788 - 44\,425)]\, 0.42992$$
$$= (0.85 \times 920 + 0.15 \times 363)\, 0.42992 = 359.6 \text{ Btu/lbm}$$

$$\dot{Q} = \dot{m}_{fuel}\, \Delta LHV = 0.0102 \text{ lbm/s} \times 359.6 \text{ Btu/lbm} = \mathbf{3.68 \text{ Btu/s}}$$

Entropy generation is from vaporizing the fuel by transfer of heat from 900 R exhaust gas to the intake system at To and then mixing it with air. The mole fractions are

Ethanol: M = 46.069; Octane: M = 114.232

$$DIV = [0.85 / 46.069] + [0.15 / 114.232] = 0.01845 + 0.001313 = 0.019764$$
$$y_{ethanol} = 0.01845 / 0.019764 = 0.9336$$
$$y_{octane} = 1 - y_{ethanol} = 0.06644$$

$$0.93356\, C_2H_5OH + 0.06644\, C_8H_{18} + 3.63118\, (O_2 + 3.76\, N_2) \Rightarrow$$
$$2.39864\, CO_2 + 3.39864\, H_2O + 13.65324\, N_2$$

C balance: $0.93356 \times 2 + 0.06644 \times 8 = 2.39864 = v_{CO2}$

H balance: $0.93356 \times 6 + 0.06644 \times 18 = 6.79728 = 2v_{H2O}$

So the A/F ratio on a mole and mass basis are

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

A/F-mole = 3.63118 × 4.76 / 1 = 17.2844;
A/F-mass = 17.2844 × 28.97/50.5996 = 9.896

The fuel was mixed before the carburetor so afterwards we have a 1: 17.2844 mix.

$s_{fg\ ethanol}$ = (67.434 – 38.321)/46.069 = 0.63194 Btu/lbm-R

$s_{fg\ octane}$ = (111.399 – 86.122)/114.232 = 0.22128 Btu/lbm-R

$s_{fg\ fuel\ mix}$ = 0.85 × 0.63194 + 0.15 × 0.22128 = 0.57034 Btu/lbm-R

M_{fuel} = 0.9336 × 46.069 + 0.06644 × 114.232 = 50.5996

Entropy Eq.: $\dot{S}_{gen} = out - in = \dot{m}_{fuel}\,[s_{fg} - R\ln(y_{fuel})] + \dot{m}_{air}\,[-R\ln(y_{air})] - \dot{Q}/T_{exhaust}$

$$= 0.0102 \times \left[0.57034 - \frac{1.98589}{50.5996}\ln\left(\frac{1}{18.2844}\right)\right] \text{Btu/s-R}$$

$$- 0.0102 \times 9.896 \times 0.06855 \ln\left(\frac{17.2844}{18.2844}\right) \text{Btu/s-R} - \frac{3.68}{900} \text{Btu/s-R}$$

= 0.00698 + 0.000389 – 0.004089 = **0.00328 Btu/s-R**

Adiabatic flame temperature

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.181E

Hydrogen gas is burned with pure oxygen in a steady flow burner where both reactants are supplied in a stoichiometric ratio at the reference pressure and temperature. What is the adiabatic flame temperature?

The reaction equation is:

$$H_2 + \nu_{O2}\, O_2 \quad => \quad H_2O$$

The balance of hydrogen is done, now for oxygen we need $\nu_{O2} = 0.5$.

Energy Eq.: $H_R = H_P$ => $0 = -103\,966 + \Delta\bar{h}_{H2O}$

=> $\Delta\bar{h}_{H2O} = 103\,966$ Btu/lbmol

Interpolate now in table F.6 for the temperature to give this enthalpy

T = 8985 R

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.182E

Some type of wood can be characterized as $C_1H_{1.5}O_{0.7}$ with a lower heating value of 8380 Btu/lbm. Find its adiabatic flame temperature when burned with stoichiometric air at 1 atm., 77 F.

$$C_1H_{1.5}O_{0.7} + \nu_{O_2}[\, O_2 + 3.76\, N_2\,] \rightarrow \quad CO_2 + 0.75\, H_2O + 3.76\nu_{O_2}\, N_2$$

O balance: $0.7 + 2\nu_{O_2} = 2 + 0.75 \quad \Rightarrow \quad \nu_{O_2} = 1.025,\ \nu_{N2} = 3.854$

$$M = 1 \times 12.0111 + 1.5 \times 1.008 + 0.7 \times 16 = 24.712$$

$$\overset{\circ}{H}_{RP} = H_P^o - H_R^o = -M \times HV = -24.712 \times 8380 = -207\,086 \text{ Btu/lbmol}$$

Energy Eq.: $H_P = \overset{\circ}{H}_P + \Delta H_P = H_R = \overset{\circ}{H}_R \quad \Rightarrow \quad \Delta H_P = \overset{\circ}{H}_R - \overset{\circ}{H}_P = -\overset{\circ}{H}_{RP}$

$$\Delta H_P = \Delta\bar{h}_{CO2} + 0.75\, \Delta\bar{h}_{H2O} + 3.854\, \Delta\bar{h}_{N2} = 207\,086 \text{ Btu/lbmol}$$

at 4400 R: $\Delta H_P = 50\,948 + 0.75 \times 41\,325 + 3.854 \times 31\,068 = 201\,678$ Btu

at 4600 R: $\Delta H_P = 53\,885 + 0.75 \times 43\,899 + 3.854 \times 32\,817 = 213\,286$ Btu

$$T = 4400 + 200\, \frac{207\,086 - 201\,678}{213\,286 - 201\,678} = \mathbf{4493\ R}$$

Comment: Most wood has some water and some non-combustible solids material so the actual flame temperature will be much lower.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.183E

Carbon is burned with air in a furnace with 150% theoretical air and both reactants are supplied at the reference pressure and temperature. What is the adiabatic flame temperature?

$$C + \nu_{O_2} O_2 + 3.76\, \nu_{O_2} N_2 \rightarrow 1\, CO_2 + 3.76\, \nu_{O_2} N_2$$

From this we find $\nu_{O_2} = 1$ and the actual combustion reaction is

$$C + 1.5\, O_2 + 5.64\, N_2 \rightarrow 1\, CO_2 + 5.64\, N_2 + 0.5\, O_2$$

$$H_P = \overset{\circ}{H}_P + \Delta H_P = H_R = \overset{\circ}{H}_R \quad \Rightarrow$$

$$\Delta H_P = \overset{\circ}{H}_R - \overset{\circ}{H}_P = 0 - (-169\,184) = 169\,184 \text{ Btu/lbmol}$$

$$\Delta H_P = \Delta \bar{h}_{CO2} + 5.64\, \Delta \bar{h}_{N2} + 0.5\, \Delta \bar{h}_{O2}$$

Find T so ΔH_P takes on the required value. To start guessing assume all products are nitrogen (1 + 5.64 + 0.5 = 7.14) that gives $3400 < T < 3600$ R from Table F.6.

$$\Delta H_{P\,3400} = 36\,437 + 5.64 \times 22\,421 + 0.5 \times 23\,644 = 174\,713 \quad \text{too high}$$
$$\Delta H_{P\,3200} = 33\,579 + 5.64 \times 20\,717 + 0.5 \times 21\,860 = 161\,353$$

Linear interpolation to find

$$T = 3200 + 200\, \frac{169\,184 - 161\,353}{174\,713 - 161\,353} = \mathbf{3317\ R}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.184E

Acetylene gas at 77 F, 14.7 lbf/in.^{2} is fed to the head of a cutting torch. Calculate the adiabatic flame temperature if the acetylene is burned with 100% theoretical air at 77 F. Repeat the answer for 100% theoretical oxygen at 77 F.

a) $C_2H_2 + 2.5\,O_2 + 2.5 \times 3.76\,N_2 \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$

$H_R = \bar{h}^o_{f\,C_2H_2} = 97\,477$ Btu

$H_P = 2(-169\,184 + \Delta\bar{h}^*_{CO_2}) + 1(-103\,966 + \Delta\bar{h}^*_{H_2O}) + 9.4\,\Delta\bar{h}^*_{N_2}$

$Q_{CV} = H_P - H_R = 0$

$\Rightarrow \quad 2\,\Delta\bar{h}^*_{CO_2} + 1\,\Delta\bar{h}^*_{H_2O} + 9.4\,\Delta\bar{h}^*_{N_2} = 539\,811$ Btu/lbmol

Trial and Error: T_{PROD} = **5236 R**

$2 \times 147\,196 + 121\,488 + 9.4 \times 89\,348 = 1\,255\,751$ **OK**

b) $C_2H_2 + 2.5\,O_2 \rightarrow 2\,CO_2 + H_2O$

$H_R = 97\,477$ Btu

$H_P = 2(-169\,184 + \Delta\bar{h}^*_{CO2}) + 1(-103\,966 + \Delta\bar{h}^*_{H2O})$

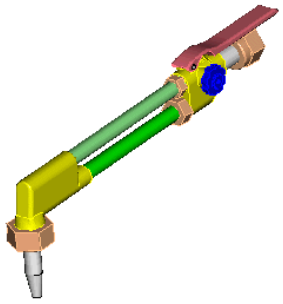
$\Rightarrow \quad 2\,\Delta\bar{h}^*_{CO2} + 1\,\Delta\bar{h}^*_{H2O} = 539\,811$

At 10 000 R (limit of F.6): $2 \times 135\,426 + 118\,440 = 389\,292$

At 9500 R: $2 \times 127\,734 + 111\,289 = 366\,757$

or 4507/100 R change, Difference, extrapolating

$$T_{PROD} \approx 10\,000 + \frac{150519}{45.07} \approx \textbf{13 340 R}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.185E

Butane gas at 77 F is mixed with 150% theoretical air at 1000 R and is burned in an adiabatic steady state combustor. What is the temperature of the products exiting the combustor?

$$C_4H_{10} + 1.5 \times 6.5(O_2 + 3.76N_2) \rightarrow 4CO_2 + 5H_2O + 3.25\ O_2 + 36.66N_2$$

$$H_R = H_R^\circ + \Delta H_{air,in}$$

$$H_P = H_P^\circ + 4\Delta\bar{h}_{CO_2} + 5\Delta\bar{h}_{H_2O} + 3.25\Delta\bar{h}_{O_2} + 36.66\Delta\bar{h}_{N_2}$$

$$H_P = H_R \Rightarrow \Delta H_P = H_R^\circ - H_P^\circ + \Delta H_{air,in}$$

$$\Delta H_P = -H_{RP}^\circ + \Delta H_{air,in} = \frac{45714}{2.326} \times 58.124 + 9.75 \times 3366 + 36.66 \times 3251$$

$$= 1\ 294\ 339 \text{ Btu/lbmol fuel}$$

$$= \left[4\Delta\bar{h}_{CO2} + 5\Delta\bar{h}_{H2O} + 3.25\Delta\bar{h}_{O2} + 36.66\Delta\bar{h}_{N2} \right] \text{ at } T_{ad}$$

Trial and Error:

Find the enthalpies from Table F.6

$$\Delta H_{P,3600R} = 1\ 281\ 185$$

$$\Delta H_{P,3800R} = 1\ 374\ 068$$

Linear interpolation to match LHS

=> **T_{ad} = 3628 R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.186E

A special coal burner uses a stoichiometric mixture of coal and an oxygen - argon mixture (1:1 mole ratio) with the reactants supplied at Po, To. Find the adiabatic flame temperature assuming complete combustion.

Combustion of carbon:

$$C + O_2 + Ar \rightarrow CO_2 + Ar$$

C.V. Combustion chamber.

Energy Eq.:

$$H_R = \overset{\circ}{H}_R = H_P = \overset{\circ}{H}_P + \Delta H_P = \bar{h}_{f\,CO_2} + \Delta\bar{h}_{CO_2} + \Delta\bar{h}_{Ar}$$

Table F.6 or F.11: $\bar{h}_{f\,CO_2}$ = -169 184 Btu/lbmol, reference $\overset{\circ}{H}_R = 0$

Table F.4: $\bar{C}_{P\,Ar} = 0.124 \times 39.948 = 4.9536$ Btu/lbmol-R

$$\Delta H_P = \overset{\circ}{H}_R - \overset{\circ}{H}_P = 0 - \bar{h}_{f\,CO_2} = 169\,184 \text{ Btu/lbmol}$$

$\Delta H_{P\,9000} = 120\,071 + 4.9536 \times (9000 - 459.7) = 162\,376$ Btu/lbmol,

$\Delta H_{P\,9500} = 127\,734 + 4.9536 \times (9500 - 459.7) = 172\,516$ Btu/lbmol,

interpolate $\Rightarrow$ $T_4 = T_{ad.flame} =$ **9336 R**

Comment: At this temperature some chemical equilibrium reactions will be important, see Chapter 14.

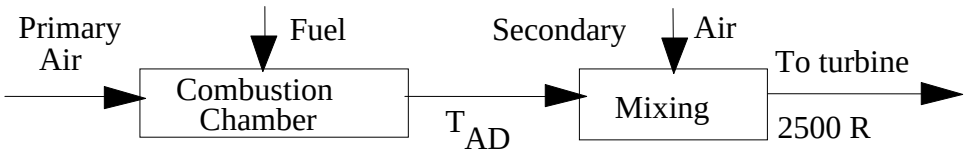
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.187E

Liquid n-butane at T_0, is sprayed into a gas turbine with primary air flowing at 150 lbf/in.^{2}, 700 R in a stoichiometric ratio. After complete combustion, the products are at the adiabatic flame temperature, which is too high so secondary air at 150 lbf/in.^{2}, 700 R is added, with the resulting mixture being at 2500 R. Show that $T_{ad} > 2500$ R and find the ratio of secondary to primary air flow.

C.V. Combustion Chamber.

$$C_4H_{10} + 6.5\ O_2 + 6.5 \times 3.76\ N_2 \rightarrow 5\ H_2O + 4\ CO_2 + 24.44\ N_2$$



$$H_R = H_{air} + H_{Fu} = H_P = H_P^\circ + \Delta H_P = H_R^\circ + \Delta H_R$$

$$\Delta H_P = H_R^\circ - H_P^\circ + \Delta H_R = -H_{RP}^\circ + \Delta H_R$$

$$= 45344 \times 58.124/2.326 + 6.5(1158 + 3.76 \times 1138)$$

$$= 1\ 168\ 433 \text{ Btu/lbmol fuel}$$

$$\Delta H_{P,2500R} = 4 \times 23755 + 5 \times 18478 + 24.44 \times 14855$$

$$= 550\ 466 \text{ Btu/lbmol fuel}$$

$$\Delta H_P > \Delta H_{P,2500R} \Rightarrow T_{ad} > 2500 \text{ R (If iteration } T_{ad} \cong 4400 \text{ R)}$$

C.V. Mixing chamber

$$\Delta H_P + \nu_{O2\ 2nd}\Delta H_{air,700} = \Delta H_{P,2500R} + \nu_{O2\ 2nd}\Delta H_{air,2500R}$$

$$\nu_{O2\ 2nd} = \frac{\Delta H_P - \Delta H_{P,2500}}{\Delta H_{air,2500} - \Delta H_{air,700}} = \frac{1168433 - 550466}{71571 - 5437} = 9.344$$

$$\text{Ratio} = \nu_{O2\ 2nd}/\nu_{O2\ Prim.} = 9.344/6.5 = \mathbf{1.44}$$

13.189E

Solid carbon is burned with stoichiometric air in a steady state process, as shown in Fig. P13.97. The reactants at T_0, P_0 are heated in a preheater to T_2 = 900 R with the energy given by the products before flowing to a second heat exchanger, which they leave at T_0. Find the temperature of the products T_4, and the heat transfer per lb mol of fuel (4 to 5) in the second heat exchanger.

a) Following the flow we have: Inlet T_1, after preheater T_2, after mixing and combustion chamber T_3, after preheater T_4, after last heat exchanger $T_5 = T_1$.

b) Products out of preheater T_4. Control volume: Total minus last heat exchanger.

$$C + O_2 + 3.76\ N_2 \rightarrow CO_2 + 3.76\ N_2$$

Energy Eq.:

$$H_R = H_R^\circ = H_{P_3} = H_P^\circ + \Delta H_{P_3} = \bar{h}_{f\,CO_2} + \Delta\bar{h}_{CO_2} + 3.76\Delta\bar{h}_{N_2}$$

$\bar{h}^\circ_{f\,CO_2}$ = -169 184 Btu/lbmol,

$\Delta H_{P_3\,4400}$ = 50 948 + 3.76 × 31068 = 167 764 Btu/lbmol,

$\Delta H_{P_3\,4600}$ = 53 885 + 3.76 × 32 817 = 177 277 Btu/lbmol

Linear interpolation $\Rightarrow T_3 = T_{ad.flame}$ = **4430 R**

c) Control volume total. Then energy equation:

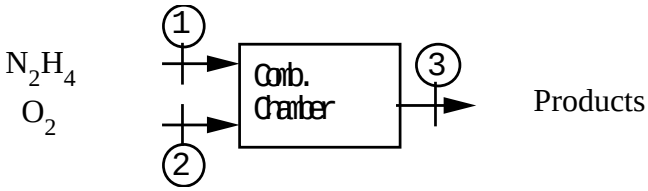
$$H_R^\circ + \bar{q} = H_P^\circ$$

$$\bar{q} = H^\circ_{RP} = \bar{h}^\circ_{f\,CO_2} - 0 = \mathbf{-169\ 184\ \frac{Btu}{lbmol\ fuel}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.190E

In a test of rocket propellant performance, liquid hydrazine (N_2H_4) at 14.7 lbf/in.^{2}, 77 F, and oxygen gas at 14.7 lbf/in.^{2}, 77 F, are fed to a combustion chamber in the ratio of 0.5 lbm O_2/lbm N_2H_4. The heat transfer from the chamber to the surroundings is estimated to be 45 Btu/lbm N_2H_4. Determine the temperature of the products exiting the chamber. Assume that only H_2O, H_2, and N_2 are present. The enthalpy of formation of liquid hydrazine is +21 647 Btu/lb mole.



$$N_2H_4 + \frac{1}{2}O_2 \rightarrow H_2O + H_2 + N_2$$

$$\dot{m}_{O2}/\dot{m}_{N2H4} = 0.5 = 32\dot{n}_{O2}/32\dot{n}_{N2H4} \quad \text{and} \quad \dot{Q}/\dot{m}_{N2H4} = -45 \text{ Btu/lbm}$$

$$\Rightarrow \quad Q_{CV} = -45 \times 32.045 = -1442 \frac{\text{Btu}}{\text{lb mol fu}}$$

C.V. combustion chamber: $\dot{n}_{Fu}\bar{h}_1 + \dot{n}_{O_2}\bar{h}_2 + \dot{Q}_{CV} = \dot{n}_{tot}\bar{h}_3$

- or - $H_1 + H_2 + Q_{CV} = H_{P_3}$ => $H_R^\circ + Q_{CV} = H_P^\circ + \Delta H_{P_3}$

$$\Delta H_{P_3} = H_R^\circ - H_P^\circ + Q_{CV} = 21\,647 + 103\,966 - 1442 = 124\,171 \frac{\text{Btu}}{\text{lb mol fuel}}$$

Trial and error on T_3:

$$\Delta H_{P\ 5000R} = 49\,114 + 34\,627 + 36\,330 = 120\,071 \text{ Btu/lbmol},$$

$$\Delta H_{P\ 5500R} = 55\,739 + 39\,032 + 40\,745 = 135\,516 \text{ Btu/lbmol},$$

Interpolate $\Rightarrow$ T_3 = **5133 R**

13.191E

Two pound moles of ammonia are burned in a steady state process with *x* lb mol of oxygen. The products, consisting of H_2O, N_2, and the excess O_2, exit at 400 F, 1000 lbf/in.^{2}.

a. Calculate *x* if half the water in the products is condensed.

b. Calculate the absolute entropy of the products at the exit conditions.

$$2NH_3 + xO_2 \rightarrow 3H_2O + N_2 + (x - 1.5)O_2$$

Products at 400 F, 1000 lbf/in^2 with $n_{H2O\ LIQ} = n_{H2O\ VAP} = 1.5$

a) $$y_{H2O\ VAP} = \frac{P_G}{P} = \frac{247.1}{1000} = \frac{1.5}{1.5 + 1 + x - 1.5}$$

$x =$ **5.070**

b) $S_{PROD} = S_{GAS\ MIX} + S_{H2O\ LIQ}$

Gas mixture:

	n_i	y_i	$\bar{s}_i^\circ$	$-\bar{R}\ln\frac{y_i P}{P_0}$	$\bar{S}_i$
H_2O	1.5	0.2471	48.939	-5.604	43.335
O_2	3.57	0.5881	52.366	-7.326	45.040
N_2	1.0	0.1648	49.049	-4.800	44.249

$S_{GAS\ MIX} = 1.5(43.335) + 3.57(45.040) + 1.0(44.249) = 270.04$ Btu/R

$S_{H2O\ LIQ} = 1.5[16.707 + 18.015(0.5647 - 0.0877)] = 37.95$ Btu/R

$S_{PROD} = 270.04 + 37.95 =$ **307.99 Btu/R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.192E

Propene, C_3H_6, is burned with air in a steady flow burner with reactants at P_o, T_o. The mixture is lean so the adiabatic flame temperature is 3200 R. Find the entropy generation per lbmol fuel neglecting all the partial pressure corrections.

The reaction equation for a mixture with excess air is:

$$C_3H_6 + \nu_{O2}\,(O_2 + 3.76\,N_2) \rightarrow 3\,H_2O + 3\,CO_2 + 3.76\nu_{O2}\,N_2 + (\nu_{O2} - 4.5)O_2$$

Energy Eq.: $H_R = H_R^\circ + \Delta H_R = H_R^\circ = H_P = H_P^\circ + \Delta H_P$

The entropy equation: $S_R + S_{gen} = S_P \quad => \quad S_{gen} = S_P - S_R = S_P - S_R^\circ$

From table F.6 at reference T

$$\Delta H_R = \Delta h_{Fu} + \nu_{O2}(\Delta h_{O2} + 3.76\,\Delta h_{N2}) = 0$$

From table F.6 at 3200 R:

$$\Delta H_P = 3\,\Delta h_{H2O} + 3\,\Delta h_{CO2} + 3.76\,\nu_{O2}\,\Delta h_{N2} + (\nu_{O2} - 4.5)\,\Delta h_{O2}$$
$$= 3 \times 26\,479 + 3 \times 33579 + 3.76\,\nu_{O2} \times 20\,717 + (\nu_{O2} - 4.5)\,21\,860$$
$$= 81\,804 + 99\,756\,\nu_{O2}$$

From table F.11:

$$H_P^\circ - H_R^\circ = 3(-103966) + 3(-169184) - 8783 = -828\,233 \text{ Btu/lbmol}$$

Now substitute all terms into the energy equation

$$-828\,233 + 81\,804 + 99\,756\,\nu_{O2} = 0$$

Solve for ν_{O2}: $\quad \nu_{O2} = \dfrac{828\,233 - 81\,804}{99\,756} = 7.48255, \quad \nu_{N2} = 28.134$

Table F.6 contains the entropies at 14.7 psia so we get:

$$S_P = 3 \times 61.796 + 3 \times 72.160 + (7.48255 - 4.5)\,63.109 + 28.134 \times 59.175$$
$$= 2254.92 \text{ Btu/lbmol-R}$$
$$S_R = 63.761 + 7.48255 \times 48.973 + 28.134 \times 45.739 = 1717.02 \text{ Btu/lbmol R}$$
$$S_{gen} = 2254.92 - 1717.02 = \mathbf{537.9\ Btu/lbmol\text{-}R}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.193E

Graphite, C, at P_o, T_o is burned with air coming in at P_o, 900 R in a ratio so the products exit at P_o, 2200 R. Find the equivalence ratio, the percent theoretical air and the total irreversibility.

$$C + x(O_2 + 3.76N_2) \rightarrow CO_2 + (x - 1)O_2 + 3.76\ x\ N_2$$

$$H_P = H_R \Rightarrow \Delta H_{P,2200} - \Delta H_R = H_R^\circ - H_P^\circ = -H_{RP}^\circ$$

$$19659 + (x - 1)13136 + 3.76 \times x \times 12407 - x(2616 + 3.76 \times 2541)$$
$$= 0 - (-169184)$$

$$\Rightarrow 6523 + x \times 47616.2 = 169184 \quad \Rightarrow \quad x = 3.416,$$

or **342 % theoretical air**

Equivalence ratio $\phi = 1/x =$ **0.293**

$$S_{gen} = s_P - s_R = \sum_P \nu_i(s_i^\circ - \bar{R}\ln y_i) - \sum_R \nu_i(s_i^\circ - \bar{R}\ln y_i)$$

R: $y_{O_2} = 0.21$ $y_{N_2} = 0.79$

P: $y_{O_2} = 0.1507$ $y_{N_2} = 0.79$ $y_{CO_2} = 0.0593$

$$S_{gen} = 66.952 + 5.610 + 2.416(59.844 + 3.758)$$
$$+ 3.76 \times 3.416(56.066 + 0.468) - 1.371$$
$$- 3.416(52.686 + 3.099 + 3.76(49.353 + 0.468))$$
$$= 120.5\ \text{Btu/(lbmol C} \times \text{R)}$$

$I = T_o S_{gen} =$ **64 677 Btu/lbmol C**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.194E

Hydrogen peroxide, H_2O_2, enters a gas generator at 77 F, 75 lbf/in.^{2} at the rate of 0.2 lbm/s and is decomposed to steam and oxygen exiting at 1500 R, 75 lbf/in.^{2}. The resulting mixture is expanded through a turbine to atmospheric pressure, 14.7 lbf/in.^{2}, as shown in Fig. P13.107. Determine the power output of the turbine, and the heat transfer rate in the gas generator. The enthalpy of formation of liquid H_2O_2 is −80 541 Btu/lb mol.

$$H_2O_2 \rightarrow H_2O + \tfrac{1}{2}O_2$$

$\dot{n}_{Fu} = \dot{m}_{Fu}/M_{Fu} = 0.2/34.015 = 0.00588$ lbmol/s

$\dot{n}_{ex,mix} = 1.5 \times \dot{n}_{Fu} = 0.00882$ lbmol/s

$\bar{C}_{p\,mix} = \frac{2}{3} \times 0.445 \times 18.015 + \frac{1}{3} \times 0.219 \times 31.999 = 7.6804$

$\bar{C}_{v\,mix} = \bar{C}_{p\,mix} - 1.98588 = 5.6945$; $k_{mix} = \bar{C}_{p\,mix}/\bar{C}_{v\,mix} = 1.3487$

Reversible turbine

$T_3 = T_2 \times (P_3/P_2)^{(k-1)/k} = 1500 \times (14.7/75)^{0.2585} = 984.3$ R

$\bar{w} = \bar{C}_{p\,mix}(T_2 - T_3) = 7.6804(1500 - 984.3) = 3960.8$ Btu/lbmol

$\dot{W}_{CV} = \dot{n}_{mix} \times \bar{w} = 0.00882 \times 3960.8 =$ **34.9 Btu/s**

C.V. Gas generator

$\dot{Q}_{CV} = \dot{H}_2 - \dot{H}_1$

$= 0.00588 \times (-103\,966 + 8306) + 0.00294(7297.5) - 0.00588(-80\,541)$

$=$ **-67.45 Btu/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.195E

Methane is burned with air both supplied at the reference conditions. There is enough excess air to give a flame temperature of 3200 R. What are the percent theoretical air and the irreversibility in the process?

The combustion equation with X times theoretical air is

$$CH_4 + 2X(O_2 + 3.76\ N_2) \rightarrow CO_2 + 2H_2O + 2(X-1)O_2 + 7.52X\ N_2$$

Energy Eq.: $H_{air} + H_{fuel} = H_R = H_P = H_P^\circ + \Delta H_P = H_R^\circ + \Delta H_R$

$$\Rightarrow \quad \Delta H_P = H_R^\circ + \Delta H_R - H_P^\circ = -H_{RP}^\circ + 0$$

From Table 13.3: $-H_{RP}^\circ = -16.04\ (-50\ 010)/2.326 = 344\ 867$ Btu/lbmol

$$\Delta H_P = \Delta \bar{h}^*_{CO2} + 2\ \Delta \bar{h}^*_{H2O} + 2(X-1)\ \Delta \bar{h}^*_{O2} + 7.52X\ \Delta \bar{h}^*_{N2}$$

From Table F.6 and the energy equation

$$\Delta H_{P\ 3200} = 33\ 579 + 2 \times 26\ 479 + 2(X-1)\ 21\ 860 + 7.52X \times 20\ 717 = 344\ 867$$

so

$$42\ 817 + 199\ 512\ X = 344\ 867 \quad => \quad X = 1.514$$

$$\%\text{Theoretical air} = \mathbf{151.4\%}$$

The products are

$$\text{Products:} \qquad CO_2 + 2H_2O + 0.9712\ O_2 + 11.172\ N_2$$

The second law

$$S_{gen} = S_P - S_R \quad \text{and} \qquad I = T_o\ S_{gen}$$

Reactants: $P_i = 14.7$ psia, $P_o = 14.7$ psia, $\bar{s}_f^o$ from Table F.6 and F.11

	n_i	y_i	$\bar{s}_f^o$	$-\bar{R} \ln \frac{y_i P_i}{P_o}$	$\bar{S}_i$ $\frac{\text{Btu}}{\text{lbmol R}}$
CH_4	1	1	44.459	0	44.459
O_2	2X	0.21	48.973	3.099	52.072
N_2	7.52 X	0.79	45.739	0.468	46.207

$$S_R = \sum n_i \bar{S}_i = 728.21 \text{ Btu/R lbmol fuel}$$

13.196E

In Example 13.15, a basic hydrogen–oxygen fuel cell reaction was analyzed at 25°C, 100 kPa. Repeat this calculation, assuming that the fuel cell operates on air at 77 F, 14.7 lbf/in.^{2}, instead of on pure oxygen at this state.

Anode: $2\,H_2 \rightarrow 4\,e^- + 4\,H^+$

Cathode: $4\,H^+ + 4\,e^- \rightarrow 1\,O_2 + 2\,H_2O$

Overall: $2\,H_2 + 1\,O_2 \rightarrow 2\,H_2O$

Example 13.15: $\Delta G_{25°C} = -474\,283$ kJ/kmol

Or $\Delta G_{77\ F} = -203\,904$ Btu/lbmol

$P_{O_2} = y_{O2} \times P = 0.21 \times 14.7 = 3.087$ lbf/in^2

$\bar{s}_{O_2} = 48.973 - 1.98589 \ln 0.21 = 52.072$

$\Delta S = 2(16.707) - 2(31.186) - 1(52.072) = -81.03$ Btu/R

$\Delta H = 2(-122\,885) - 2(0) - 1(0) = -245\,770$ Btu/lbmol

$\Delta G_{77\ F} = -245\,770 - 536.67(-81.03) = 202\,284$ Btu/lbmol

$E° = -\Delta G/N_0 e\, n_e = 202\,284 \times 2.326/(96\,485 \times 4) =$ **1.219 V**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.197E

Pentane is burned with 120% theoretical air in a constant pressure process at 14.7 lbf/in^2. The products are cooled to ambient temperature, 70 F. How much mass of water is condensed per pound-mass of fuel? Repeat the answer, assuming that the air used in the combustion has a relative humidity of 90%.

$$C_5H_{12} + 1.2 \times 8\,(O_2 + 3.76\,N_2) \rightarrow 5\,CO_2 + 6\,H_2O + 0.96\,O_2 + 36.1\,N_2$$

Products cooled to 70 F, 14.7 lbf/in^2

a) for H_2O at 70 F: $P_G = 0.3632$ lbf/in^2

$$y_{H2O\ MAX} = \frac{P_G}{P} = \frac{0.3632}{14.7} = \frac{n_{H2O\ MAX}}{n_{H2O\ MAX} + 42.06}$$

Solving, $n_{H2O\ MAX} = 1.066 < n_{H2O}$

Therefore, $n_{H2O\ VAP} = 1.066$, $n_{H2O\ LIQ} = 6 - 1.066 = 4.934$

$$m_{H2O\ LIQ} = \frac{4.934 \times 18.015}{72.151} = \mathbf{1.232\ lbm/lbm\ fuel}$$

b) $P_{v1} = 0.9 \times 0.3632 = 0.3269$ lbf/in^2

$$w_1 = 0.622 \times \frac{0.3269}{14.373} = 0.014\,147$$

$$n_{H2O\ IN} = 0.014147 \times \frac{28.97}{18.015} \times (9.6 + 36.1) = 1.040\ \text{lbmol}$$

$$n_{H2O\ OUT} = 1.04 + 6 = 7.04$$

$$n_{H2O\ LIQ} = 7.04 - 1.066 = 5.974\ \text{lb mol}$$

$$n_{H2O\ LIQ} = \frac{5.974 \times 18.015}{72.151} = \mathbf{1.492\ lbm/lbm\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.198E

A small air-cooled gasoline engine is tested, and the output is found to be 2.0 hp. The temperature of the products is measured and found to be 730 F. The products are analyzed on a dry volumetric basis, with the following result 11.4% CO_2, 2.9% CO, 1.6% O_2 and 84.1% N_2. The fuel may be considered to be liquid octane. The fuel and air enter the engine at 77 F, and the flow rate of fuel to the engine is 1.8 lbm/h. Determine the rate of heat transfer from the engine and its thermal efficiency.

$$a\, C_8H_{18} + b\, O_2 + 3.76b\, N_2 \rightarrow 11.4\, CO_2 + 2.9\, CO + c\, H_2O + 1.6\, O_2 + 84.1\, N_2$$

$b = 84.1/3.76 = 22.37, \quad a = (1/8)(11.4 + 2.9) = 1.788, \quad c = 9a = 16.088$

$$C_8H_{18} + 12.5\, O_2 + 47.1\, N_2 \rightarrow 6.38\, CO_2 + 1.62\, CO + 9\, H_2O + 0.89\, O_2 + 47.1\, N_2$$

a) $H_R = \bar{h}^\circ_{f\,C8H18} = -107\,526$ Btu/lbmol

$H_P = 6.38(-169\,184 + 6807) + 1.62(-47\,518 + 4647)$

$+ 9(-103\,966 + 5475) + 0.89(0+4822)$

$+ 47.1(0 + 4617) = -1\,770\,092$ Btu/lbmol

$H_P - H_R = -1\,770\,092 - (-107\,526) = -1\,662\,566$ Btu/lbmol

$$\dot{H}_P - \dot{H}_R = \frac{1.8}{114.23}(-1\,662\,566) = -26\,198 \text{ Btu/h} \quad (M_{fuel} = 114.23)$$

$$\dot{Q}_{CV} = -26\,198 + 2.0\,(2544) = \mathbf{-21\,110\ Btu/h}$$

b) Fuel heating value from table 15.3 converted to Btu/lbm

$$\dot{Q}_H = 1.8 \times (47\,893/2.326) = 37\,062 \text{ Btu/h}$$

$$\dot{W}_{NET} = 2.0 \times 2544 = 5088 \text{ Btu/h}; \qquad \eta_{TH} = \frac{5088}{37062} = \mathbf{0.137}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.199E

A gasoline engine uses liquid octane and air, both supplied at P_o, T_o, in a stoichiometric ratio. The products (complete combustion) flow out of the exhaust valve at 2000 R. Assume that the heat loss carried away by the cooling water, at 200 F, is equal to the work output. Find the efficiency of the engine expressed as (work/lower heating value) and the second law efficiency.

$$C_8H_{18} + 12.5(O_2 + 3.76N_2) \rightarrow 8\ CO_2 + 9\ H_2O + 47\ N_2$$

Table 13.3 LHV convert units kJ/kg to Btu/lbm

LHV = 44 425 × 114.232 / 2.326 = 2 181 753 Btu/lbmol fuel

Table F.6

$$\Delta H_{P,2000} = 8 \times 16\,982 + 9 \times 13\,183 + 47 \times 10\,804 = 643\,470$$

C.V. Total engine: $H_{in} = H_{ex} + W + Q_{loss} = H_{ex} + 2W$

$$W = (H_{in} - H_{ex})/2 = (H_R - H_P)/2 = (-H^\circ_{RP} - \Delta H_{P,2000})/2$$
$$= (2\,181\,753 - 643\,470)/2 = 769\,142 \text{ Btu/lbmol fuel}$$

$$\eta_{TH} = W/LHV = 769\,142/2\,181\,753 = \mathbf{0.353}$$

For 2nd law efficiency we must find reversible work

$$\bar{S}_{in} = \bar{s}_{fuel} + 12.5(\bar{s}_{O_2} + 3.76\bar{s}_{N_2})$$
$$= 86.122 + 12.5\left[48.973 - 1.98589 \ln (1 / 4.76)\right]$$
$$+ 47\left[45.739 - 1.98589 \ln (3.76 / 4.76)\right]$$
$$= 2908.8 \text{ Btu/(lbmol fuel} \times \text{R)}$$

$$\bar{S}_{ex} = 8\bar{s}_{CO_2} + 9\bar{s}_{H_2O} + 47\bar{s}_{N_2} = 8\left[65.677 - 1.98589 \ln (8 / 64)\right]$$
$$+ 9\left[56.619 - 1.98589 \ln \left(\frac{9}{64}\right)\right] + 47\left[55.302 - 1.98589 \ln \left(\frac{47}{64}\right)\right]$$
$$= 3731.1 \text{ Btu/(lbmol fuel} \times \text{R)}$$

Assume the same Q_{loss} out to 200 F = 659.67 R reservoir and compute Q_0^{rev}:

$$\bar{S}_{in} + Q_0^{rev}/T_0 = \bar{S}_{ex} + Q_{loss}/T_{res}$$

$$Q_0^{rev} = T_0(\bar{S}_{ex} - \bar{S}_{in}) + Q_{loss} T_0/T_{res}$$
$$= 536.67(3731.1 - 2908.8) + 769\,142*536.67/659.67$$
$$= 1\,067\,034 \text{ Btu/lbmol fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

$$W^{rev} = H_{in} - H_{ex} - Q_{loss} + Q_0^{rev} = W_{ac} + Q_0^{rev}$$

$$= 769\ 142 + 1\ 067\ 034 = 1\ 836\ 176 \text{ Btu/lbmol fuel}$$

$$\eta_{II} = W_{ac}/W^{rev} = 769\ 142/1\ 836\ 176 = \mathbf{0.419}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.200E

Ethene, C_2H_4, and propane, C_3H_8, in a 1:1 mole ratio as gases are burned with 120% theoretical air in a gas turbine. Fuel is added at 77 F, 150 lbf/in.^{2} and the air comes from the atmosphere, 77 F, 15 lbf/in.^{2} through a compressor to 150 lbf/in.^{2} and mixed with the fuel. The turbine work is such that the exit temperature is 1500 R with an exit pressure of 14.7 lbf/in.^{2}. Find the mixture temperature before combustion, and also the work, assuming an adiabatic turbine.

$$C_2H_4 + C_3H_8 + \nu_{O2}(O_2+3.76N_2) \rightarrow 5CO_2 + 6H_2O + \nu_{N2}N_2$$

$$\phi = 1 \Rightarrow \quad \nu_{O2} = 8 \qquad \phi = 1/1.2 \quad \Rightarrow \quad \nu_{O2} = 9.6$$

so we have 45.696 lbmol air per 2 lbmol fuel

$$C_2H_4 + C_3H_8 + 9.6(O_2 + 3.76N_2) \rightarrow 5CO_2 + 6H_2O + 1.6\ O_2 + 36.096N_2$$

C.V. Compressor (air flow)

$$w_{c,in} = h_2 - h_1 \qquad s_2 = s_1 \Rightarrow \quad P_{r1} = 1.0907$$

$$P_{r2} = P_{r1}P_2/P_1 = 10.907 \Rightarrow \quad T_{2\ air} = 1027.3\ R$$

$$w_{c,in} = 247.81 - 128.38 = 119.53\ Btu/lbm = 3462.4\ Btu/lbmol\ air$$

C.V. Mixing chamber

$$\dot{n}_{air}\bar{h}_{air\ in} + \dot{n}_{fu1}\bar{h}_{fu1} + \dot{n}_{fu2}\bar{h}_{fu2} = (same)_{exit}$$

$$(\bar{C}_{PF1} + \bar{C}_{PF2})(T_{ex} - T_0) = 45.696\ \bar{C}_{P\ air}(T_{2\ air} - T_{ex})$$

$$\bar{C}_{PF1} = 11.53, \quad \bar{C}_{PF2} = 17.95, \quad \bar{C}_{P\ air} = 6.953\ \ Btu/lbmol\text{-}R$$

$$T_{ex} = \frac{45.696\bar{C}_{P\ air}T_2 + (\bar{C}_{PF1} + \bar{C}_{PF2})T_0}{\bar{C}_{PF1} + \bar{C}_{PF2} + 45.696\bar{C}_{\ air}} = \mathbf{985.6\ R} = T_{in\ combust}$$

Turbine work: take C.V. total and subtract compressor work.

$$W_{total} = H_{in} - H_{out} = H_R - H_{P,1500}$$

$$= \bar{h}^\circ_{f\ F1} + \bar{h}^\circ_{f\ F2} - 5\bar{h}_{CO2} - 6\bar{h}_{H2O} - 36.096\bar{h}_{N2} - 1.6\bar{h}_{O2}$$

$$= 22557 + (-44669) - 5(10557 - 169184)$$

$$- 6(8306 - 103966) - 36.096 \times 6925 - 1.6 \times 7297.5$$

$$= 1\ 083\ 342\ Btu/2\ lbmol\ Fuel$$

$$w_T = w_{tot} + w_{c,in} = 1\ 083\ 342 + 3462.4 \times 45.696$$

$$= \mathbf{1\ 241\ 560\ Btu/2\ lbmol\ fuel}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

13.201E

Repeat problem 13.190E, but assume that saturated-liquid oxygen at 170 R is used instead of 77 F oxygen gas in the combustion process. Use the generalized charts to determine the properties of liquid oxygen.

Problem the same as 13.190E, except oxygen enters at state 2 as saturated liquid at 170 R.

At 170 R, $T_{r2} = \dfrac{170}{278.6} = 0.61 \Rightarrow \Delta\bar{h}_f = 5.1$

From Fig. D.2:

$$(\bar{h}^* - \bar{h}) = 1.98589 \times 278.6 \times 5.1 = 2822 \text{ Btu/lbmol}$$

$$\Delta H_{P3} = H_R^\circ + \Delta H_R - H_P^\circ + Q_{CV} = 21\,647 - 0.5(2822)$$

$$+ 0.5(0.219)(170 - 536.67)(32) + 103\,966 - 1442$$

$$= 121\,475 \text{ Btu/lbmol}$$

With

$$\Delta H_{P\ 5000R} = 49\,114 + 34\,627 + 36\,330 = 120\,071 \text{ Btu/lbmol},$$

$$\Delta H_{P\ 5500R} = 55\,739 + 39\,032 + 40\,745 = 135\,516 \text{ Btu/lbmol},$$

Linear interpolation $\Rightarrow T_3 =$ **5045 R**

In-Text Concept Questions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.a

For a mixture of O_2 and O the pressure is increased at constant T; what happens to the composition?

An increase in pressure causes the reaction to go toward the side of smaller total number of moles, in this case toward the O_2 .

14.b

For a mixture of O_2 and O the temperature is increased at constant P; what happens to the composition?

A temperature increase causes more O_2 to dissociate to O.

14.c

For a mixture of O_2 and O I add some argon keeping constant T, P; what happens to the moles of O?

Diluting the mixture with a non-reacting gas has the same effect as decreasing the pressure, causing the reaction to shift toward the side of larger total number of moles, in this case the O.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.d

When dissociations occur after combustion, does T go up or down?

Dissociation reactions of combustion products lower the temperature.

14.e

For nearly all the dissociations and ionization reactions what happens with the composition when the pressure is raised?

The reactions move towards the side with fewer moles of particles, that is ions and electrons towards the monatomic side and monatomic species combine to form the molecules (diatomic or more)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.f

How does the time scale for NO formation change when P is lower at same T?

Look at the expression for the time scale in Eq.14.40. As P is lowered the time scale becomes larger. The formation rates drops, and the effect is explained by the larger distance between the molecules/atoms (density lower), the same T essentially means that they have the same characteristic velocity.

14.g

Which atom in air ionizes first as T increases? What is the explanation?

Using Fig. 14.11, we note that as temperature increases, atomic N ionizes to N^+, becoming significant at about 6-8000 K. N has a lower ionization potential compared to O or Ar.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

Concept-Study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.1

Is the concept of equilibrium limited to thermodynamics?

Equilibrium is a condition in which the driving forces present are balanced, with no tendency for a change to occur spontaneously. This concept applies to many diverse fields of study – one no doubt familiar to the student being that of mechanical equilibrium in statics, or engineering mechanics.

14.2

How does Gibbs function vary with quality as you move from liquid to vapor?

There is no change in Gibbs function between liquid and vapor. For equilibrium we have $g_g = g_f$.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.3

How is a chemical equilibrium process different from a combustion process?

Chemical equilibrium occurs at a given state, T and P, following a chemical reaction process, possibly a combustion (which is a chemical reaction process) together with several reactions amongst the combustion products. Whereas the combustion is a one-way process (irreversible) the chemical equilibrium is a reversible process that can proceed in both directions.

14.4

Must P and T be held fixed to obtain chemical equilibrium?

No, but we commonly evaluate the condition of chemical equilibrium at a state corresponding to a given temperature and pressure. If T and P changes in a process it means that the chemical composition adjusts towards equilibrium and the composition changes along with the process.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.5

The change in Gibbs function ΔG^o for a reaction is a function of which property?

The change in Gibbs function for a reaction ΔG is a function of T and P.
The change in standard-state Gibbs function ΔG^o is a function only of T.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.6

In a steady flow burner T is not controlled, which properties are?

The pressure tends to be constant, only minor pressure changes due to acceleration of the products as density decreases velocity must increase to have the same mass flow rate. The product temperature depends on heat losses (radiation etc.) and any chemical reactions that may take place generally lowering the temperature below the standard adiabatic flame temperature.

14.7

In a closed rigid combustion bomb which properties are held fixed?

The volume is constant. The number of atoms of each element is conserved, although the amounts of various chemical species change. As the products have more internal energy but cannot expand the pressure increases significantly.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.8

Is the dissociation of water pressure sensitive?

Yes, since the total number of moles on the left and right sides of the reaction equation(s) is not the same.

14.9

At 298 K, K = exp(−184) for the water dissociation, what does that imply?

This is an extremely small number, meaning that the reaction tends to go strongly from right to left – in other words, does not tend to go from left to right (dissociation of water) at all.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.10

If a reaction is insensitive to pressure prove that it is also insensitive to dilution effects at a given T.

Assume the standard reaction we used to develop the expression for the equilibrium constant: $\nu_A\, A + \nu_B\, B \Leftrightarrow \nu_C\, C + \nu_D\, D$
let us assume we add an inert component E so the total moles become:

$$n_{tot} = n_A + n_B + n_C + n_D + n_E$$

This will now lower the mole fractions of A, B, C, and D. If the reaction is pressure insensitive then: $\nu_A + \nu_B = \nu_C + \nu_D$ and the equilibrium equation becomes:

$$K = \frac{y_C^{\nu_C}\, y_D^{\nu_D}}{y_A^{\nu_A}\, y_B^{\nu_B}} \left(\frac{P}{P^o}\right)^{\nu_C + \nu_D - \nu_A - \nu_B} = \frac{y_C^{\nu_C}\, y_D^{\nu_D}}{y_A^{\nu_A}\, y_B^{\nu_B}}$$

Since each $y_i = n_i / n_{tot}$ we get:

$$K = \frac{y_C^{\nu_C}\, y_D^{\nu_D}}{y_A^{\nu_A}\, y_B^{\nu_B}} = \frac{(n_C/n_{tot})^{\nu_C}\, (n_D/n_{tot})^{\nu_D}}{(n_A/n_{tot})^{\nu_A}\, (n_B/n_{tot})^{\nu_B}}$$

$$= \frac{n_C^{\nu_C}\, n_D^{\nu_D}}{n_A^{\nu_A}\, n_B^{\nu_B}}\, n_{tot}^{\nu_A + \nu_B - \nu_C - \nu_D} = \frac{n_C^{\nu_C}\, n_D^{\nu_D}}{n_A^{\nu_A}\, n_B^{\nu_B}}$$

Now we see that the total number of moles that includes n_E does not enter the equation and thus will not affect any progress of the reaction.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.11

For a pressure sensitive reaction an inert gas is added (dilution), how does the reaction shift?

Assume the standard reaction we used to develop the expression for the equilibrium constant: $\nu_A\, A + \nu_B\, B \Leftrightarrow \nu_C\, C + \nu_D\, D$
let us assume we add an inert component E so the total moles become:

$$n_{tot} = n_A + n_B + n_C + n_D + n_E$$

This will now lower the mole fractions of A, B, C, and D. If the reaction is pressure sensitive then: $\nu_A + \nu_B \neq \nu_C + \nu_D$ and the equilibrium equation becomes:

$$K = \frac{y_C^{\nu_C}\, y_D^{\nu_D}}{y_A^{\nu_A}\, y_B^{\nu_B}} \left(\frac{P}{P^o}\right)^{\nu_C + \nu_D - \nu_A - \nu_B}$$

Since each $y_i = n_i / n_{tot}$ we get:

$$K = \frac{(n_C/n_{tot})^{\nu_C}\, (n_D/n_{tot})^{\nu_D}}{(n_A/n_{tot})^{\nu_A}\, (n_B/n_{tot})^{\nu_B}} \left(\frac{P}{P^o}\right)^{\nu_C + \nu_D - \nu_A - \nu_B}$$

$$= \frac{n_C^{\nu_C}\, n_D^{\nu_D}}{n_A^{\nu_A}\, n_B^{\nu_B}} \left(\frac{P}{P^o\, n_{tot}}\right)^{\nu_C + \nu_D - \nu_A - \nu_B}$$

As n_{tot} is raised due to n_E it acts as if the pressure P is lowered thus pushing the reaction towards the side with a larger number of moles.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.12

In a combustion process is the adiabatic flame temperature affected by reactions?

The adiabatic flame temperature is lower due to dissociation reactions of the products as those products absorb some of the energy, i.e. 2 O atoms have more energy, h = 2(249 170 + Δh) than a single O_2 molecule, h = Δh, see Table A.9. The temperature is also influenced by other reactions like the water gas reaction.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.13

In equilibrium Gibbs function of the reactants and the products is the same; how about the energy?

The chemical equilibrium mixture at a given T, P has a certain total internal energy. There is no restriction on its division among the constituents. The conservation of energy from the reactants to the products will determine the temperature so if it takes place in a fixed volume (combustion bomb) then U is constant whereas if it is in a flow (like a steady flow burner) then H is constant. When this is combined with chemical equilibrium it is actually a lengthy procedure to determine both the composition and the temperature in the actual process.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.14

Does a dissociation process require energy or does it give out energy?

Dissociation reactions require energy and is thus endothermic. Notice from Table A.9 that all the atoms (N, O, H) has a much higher formation enthalpy than the diatomic molecules (which have formation enthalpy equal to zero).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.15

If I consider the non-frozen (composition can vary) specific heat, but still assume all components are ideal gases, does that C become a function of temperature? of pressure?

The non-frozen mixture heat capacity will be a function of both T and P, because the mixture composition depends on T and P, while the individual component specific heat capacities depend only on T.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.16

What is K for the water gas reaction in Example 14.4 at 1200 K?

Using the result of Example 14.4 and Table A.11

$$\ln K = \frac{1}{2}(\ln K_I - \ln K_{II})$$

$$= 0.5\,[-35.736 - (-36.363)] = +0.3135\ ,$$

$$K = 1.3682$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.17

What would happen to the concentrations of the monatomic species like O, N if the pressure is higher in Fig. 14.11

Since those reaction are pressure sensitive (more moles on RHS than on LHS) the higher pressure will push these reactions to the left and reduce the concentrations of the monatomic species.

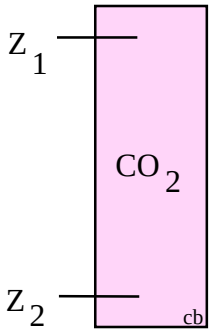
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

Equilibrium and Phase Equilibrium

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.18

Carbon dioxide at 15 MPa is injected into the top of a 5-km deep well in connection with an enhanced oil-recovery process. The fluid column standing in the well is at a uniform temperature of 40°C. What is the pressure at the bottom of the well assuming ideal gas behavior?



$(Z_1 - Z_2) = 5000$ m, $P_1 = 15$ MPa

$T = 40\ ^{o}C$ = constant

Equilibrium at constant T

$$-w_{REV} = 0 = \Delta g + \Delta PE$$

$$= RT \ln (P_2/P_1) + g(Z_2 - Z_1) = 0$$

$$\ln (P_2/P_1) = \frac{9.807 \times 5000}{1000 \times 0.188\ 92 \times 313.2} = 0.8287$$

$P_2 = 15$ MPa exp(0.8287) = **34.36 MPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.19

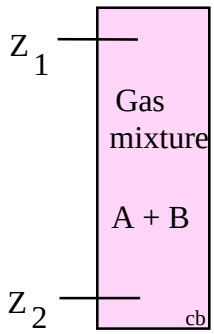
Consider a 2-km-deep gas well containing a gas mixture of methane and ethane at a uniform temperature of 30°C. The pressure at the top of the well is 14 MPa, and the composition on a mole basis is 90% methane, 10% ethane. Each component is in equilibrium (top to bottom) with dG + g dZ = 0 and assume ideal gas, so for each component Eq.14.10 applies. Determine the pressure and composition at the bottom of the well.



$(Z_1 - Z_2) = 2000$ m, Let A = CH_4, B = C_2H_6

$P_1 = 14$ MPa, $y_{A1} = 0.90$, $y_{B1} = 0.10$

T = 30 °C = constant

From section 14.1, for A to be at equilibrium between

1 and 2: $W_{REV} = 0 = n_A(\bar{G}_{A1} - \bar{G}_{A2}) + n_A M_A g (Z_1 - Z_2)$

Similarly, for B: $W_{REV} = 0 = n_B(\bar{G}_{B1} - \bar{G}_{B2}) + n_B M_B g (Z_1 - Z_2)$

Using eq. 14.10 for A: $\bar{R}T \ln (P_{A2}/P_{A1}) = M_A g (Z_1 - Z_2)$

with a similar expression for B. Now, ideal gas mixture, $P_{A1} = y_{A1}P$, etc.

Substituting: $$\ln \frac{y_{A2}P_2}{y_{A1}P_1} = \frac{M_A g(Z_1-Z_2)}{\bar{R}T} \quad \text{and} \quad \ln \frac{y_{B2}P_2}{y_{B1}P_1} = \frac{M_B g(Z_1-Z_2)}{\bar{R}T}$$

$$\ln (y_{A2} P_2) = \ln(0.9\times14) + \frac{16.04\times9.807(2000)}{1000\times8.3145\times303.2} = 2.6585$$

$$\Rightarrow \quad y_{A2} P_2 = 14.2748$$

$$\ln (y_{B2}P_2) = \ln(0.1\times14) + \frac{30.07\times9.807(2000)}{1000\times8.3145\times303.2} = 0.570\ 43$$

$$\Rightarrow \quad y_{B2} P_2 = (1 - y_{A2}) P_2 = 1.76903$$

Solving: $P_2 =$ **16.044 MPa** & $y_{A2} =$ **0.8897**

14.20

A container has liquid water at 20°C , 100 kPa in equilibrium with a mixture of water vapor and dry air also at 20°C, 100 kPa. How much is the water vapor pressure and what is the saturated water vapor pressure?

From the steam tables we have for saturated liquid:

$$P_g = \mathbf{2.339\ kPa}, \quad v_f = 0.001002\ m^3/kg$$

The liquid is at 100 kPa so it is compressed liquid still at 20°C so from Eq.14.15 at constant T

$$g_{liq} - g_f = \int v\, dP = v_f\,(P - P_g)$$

The vapor in the moist air is at the partial pressure P_v also at 20°C so we assume ideal gas for the vapor

$$g_{vap} - g_g = \int v\, dP = RT \ln \frac{P_v}{P_g}$$

We have the two saturated phases so $g_f = g_g$ ($q = h_{fg} = Ts_{fg}$) and now for equilibrium the two Gibbs function must be the same as

$$g_{vap} = g_{liq} = RT \ln \frac{P_v}{P_g} + g_g = v_f\,(P - P_g) + g_f$$

leaving us with

$$\ln \frac{P_v}{P_g} = v_f\,(P - P_g)/\,RT = \frac{0.001002\ (100 - 2.339)}{0.4615 \times 293.15} = 0.000723$$

$$P_v = P_g \exp(0.000723) = \mathbf{2.3407\ kPa}.$$

This is only a minute amount above the saturation pressure. For the moist air applications in Chapter 11 we neglected such differences and assumed the partial water vapor pressure at equilibrium (100% relative humidity) is P_g. The pressure has to be much higher for this to be a significant difference.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.21

Using the same assumptions as those in developing Eq. d in Example 14.1, develop an expression for pressure at the bottom of a deep column of liquid in terms of the isothermal compressibility, β_T. For liquid water at 20°C, $\beta_T = 0.0005$ [1/MPa]. Use the result of the first question to estimate the pressure in the Pacific ocean at the depth of 3 km.

$$d g_T = v^\circ (1 - \beta_T P)\, dP_T \qquad d g_T + g\, dz = 0$$

$$v^\circ (1 - \beta_T P)\, dP_T + g\, dz = 0 \quad \text{and integrate} \quad \int v^\circ (1-\beta_T P)\, dP_T = -g \int dz$$

$$\int_{P_0}^{P} (1-\beta_T P)\, dP_T = +\frac{g}{v^\circ} \int_0^{+H} dz \quad \Rightarrow \quad P - P_0 - \beta_T \frac{1}{2} [P^2 - P_0{}^2] = \frac{g}{v^\circ} H$$

$$P \left(1 - \frac{1}{2} \beta_T P\right) = P_0 - \frac{1}{2} \beta_T P_0{}^2 + \frac{g}{v^\circ} H$$

$v^\circ = v_{f\ 20°C} = 0.001002$; $H = 3000$ m, $g = 9.80665$ m/s^2; $\beta_T = 0.0005$ 1/MPa

$$P \left(1 - \frac{1}{2} \times 0.0005\, P\right) = 0.101 - \frac{1}{2} \times 0.0005 \times 0.101^2$$

$$+ [9.80665 \times 3000/0.001002] \times 10^{-6}$$

$$= 29.462 \text{ MPa}, \quad \text{which is close to P}$$

Solve by iteration or solve the quadratic equation

$$P = \mathbf{29.682\ MPa}$$

14.22

Which of the reactions listed in Table A.11 are pressure sensitive?

Check if: $\nu_A + \nu_B \neq \nu_C + \nu_D$

Reaction	Check	P sensitive?
$H_2 \Leftrightarrow 2H$	1 < 2	yes
$O_2 \Leftrightarrow 2O$	1 < 2	yes
$N_2 \Leftrightarrow 2N$	1 < 2	yes
$2\,H_2O \Leftrightarrow 2\,H_2 + 1\,O_2$	2 < 3	yes
$2\,H_2O \Leftrightarrow 2\,H_2 + 2\,OH$	2 < 4	yes
$2\,CO_2 \Leftrightarrow 2\,CO + 1\,O_2$	2 < 3	yes
$N_2 + O_2 \Leftrightarrow 2\,NO$	2 = 2	no
$N_2 + 2O_2 \Leftrightarrow 2\,NO_2$	3 > 2	yes

Most of them have more moles on RHS and thus will move towards the RHS if the pressure is lowered. Only the last one has the opposite and will move towards the LHS if the pressure is lowered.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.23

Calculate the equilibrium constant for the reaction $O_2 \Leftrightarrow 2O$ at temperatures of 298 K and 6000 K. Verify the result with Table A.11.

Reaction $O_2 \Leftrightarrow 2O$

At 25 °C (298.15 K):

$$\Delta H^0 = 2\bar{h}^0_{f\,O} - 1\bar{h}^0_{f\,O2} = 2(249\,170) - 1(0) = 498\,340 \text{ kJ/kmol}$$

$$\Delta S^0 = 2\bar{s}^0_{O} - 1\bar{s}^0_{O2} = 2(161.059) - 1(205.148) = 116.97 \text{ kJ/kmol K}$$

$$\Delta G^0 = \Delta H^0 - T\Delta S^0 = 498\,340 - 298.15 \times 116.97 = 463\,465 \text{ kJ/kmol}$$

$$\ln K = -\frac{\Delta G^0}{\bar{R}T} = -\frac{463\,465}{8.3145 \times 298.15} = \mathbf{-186.961}$$

At 6000 K:

$$\Delta H^0 = 2(249\,170 + 121\,264) - (0 + 224\,210) = 516\,658 \text{ kJ/kmol}$$

$$\Delta S^0 = 2(224.597) - 1(313.457) = 135.737 \text{ kJ/kmol K}$$

$$\Delta G^0 = 516\,658 - 6000 \times 135.737 = -297\,764 \text{ kJ/kmol}$$

$$\ln K = \frac{+297\,764}{8.3145 \times 6000} = \mathbf{+5.969}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.24

Calculate the equilibrium constant for the reaction $H_2 \Leftrightarrow 2H$ at a temperature of 2000 K, using properties from Table A.9. Compare the result with the value listed in Table A.11.

From Table A.9 at 2000 K we find:

$$\Delta\bar{h}_{H_2} = 52\,942 \text{ kJ/kmol}; \quad \bar{s}_{H_2} = 188.419 \text{ kJ/kmol K}; \quad \bar{h}_f^o = 0$$

$$\Delta\bar{h}_H = 35\,375 \text{ kJ/kmol}; \quad \bar{s}_H = 154.279 \text{ kJ/kmol K}; \quad \bar{h}_f^o = 217\,999 \text{ kJ/kmol}$$

$$\Delta G^0 = \Delta H - T\Delta S = H_{RHS} - H_{LHS} - T\,(S^0_{RHS} - S^0_{LHS})$$

$$= 2 \times (35\,375 + 217\,999) - 52943 - 2000(2\times 154.279 - 182.419)$$

$$= 213\,528 \text{ kJ/kmol}$$

$$\ln K = -\Delta G^0/\bar{R}T = -213\,528 / (8.3145 \times 2000) = -12.8407$$

Table A.11 $\ln K = -12.841$ OK

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.25

For the dissociation of oxygen, $O_2 \Leftrightarrow 2O$, around 2000 K we want a mathematical expression for the equilibrium constant K(T). Assume constant heat capacity, at 2000 K, for O_2 and O from Table A.9 and develop the expression from Eqs. 14.12 and 14.15.

From Eq.14.15 the equilibrium constant is

$$K = \exp\left(-\frac{\Delta G^0}{\bar{R}T}\right); \qquad \Delta G^0 = \Delta H^0 - T\,\Delta S^0$$

and the shift is

$$\Delta G^0 = 2\,\bar{h}_O - \bar{h}_{O2} - T(2\bar{s}^o_O - \bar{s}^o_{O_2})$$

Substitute the first order approximation to the functions $\bar{h}$ and $\bar{s}^o$ as

$$\bar{h} = \bar{h}_{2000\ K} + \bar{C}_p\,(T - 2000); \quad \bar{s}^o = \bar{s}^o_{2000\ K} + \bar{C}_p \ln\frac{T}{2000}$$

The properties are from Table A.9 and $\bar{R}$ = 8.3145 kJ/kmol K

Oxygen O_2: $\bar{h}_{2000\ K}$ = 59 176 kJ/kmol, $\bar{s}^o_{2000\ K}$ = 268.748 kJ/kmol K

$$\bar{C}_p = \frac{\bar{h}_{2200\ K} - \bar{h}_{2200\ K}}{2200 - 1800} = \frac{66\,770 - 51\,674}{400} = 37.74 \text{ kJ/kmol K}$$

Oxygen O: $\bar{h}_{2000\ K}$ = 35 713 + 249 170 = 284 883 kJ/kmol,

$\bar{s}^o_{2000\ K}$ = 201.247 kJ/kmol K

$$\bar{C}_p = \frac{\bar{h}_{2200\ K} - \bar{h}_{2200\ K}}{2200 - 1800} = \frac{39\,878 - 31\,547}{400} = 20.8275 \text{ kJ/kmol K}$$

Substitute and collect terms

$$\frac{\Delta G^0}{\bar{R}T} = \frac{\Delta H^0}{\bar{R}T} - \frac{\Delta S^0}{\bar{R}} = \frac{\Delta H^0_{2000}}{\bar{R}T} + \frac{\Delta \bar{C}_{p\ 2000}}{\bar{R}}\left[\frac{T - 2000}{T} - \ln\frac{T}{2000}\right] - \frac{\Delta S^0_{2000}}{\bar{R}}$$

Now we have

$$\Delta H^0_{2000}/\bar{R} = (2 \times 284\,883 - 59\,176)/8.3145 = 61\,409.6 \text{ K}$$

$$\Delta \bar{C}_{p\ 2000}/\bar{R} = (2 \times 20.8275 - 37.74)/8.3145 = 0.470864$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

$$\Delta S^0_{2000}/\bar{R} = (2 \times 201.247 - 268.748)/8.3145 = 16.08587$$

so we get

$$\frac{\Delta G^0}{\bar{R}T} = \frac{61\ 409.6}{T} + 0.470864 \left[\frac{T - 2000}{T} - \ln \frac{T}{2000} \right] - 16.08587$$

$$= \frac{60\ 467.9}{T} - 15.615 - 0.470864 \ln \frac{T}{2000}$$

Now the equilibrium constant K(T) is approximated as

$$K(T) = \exp \left[15.615 - \frac{60\ 467.9}{T} + 0.470864 \ln \frac{T}{2000} \right]$$

Remark: We could have chosen to expand the function $\Delta G^0/\bar{R}T$ as a linear expression instead or even expand the whole $\exp(-\Delta G^0/\bar{R}T)$ in a linear function.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.26

Find K for: $CO_2 \Leftrightarrow CO + 1/2O_2$ at 3000 K using A.11

The elementary reaction in A.11 is : $2CO_2 \Leftrightarrow 2CO + O_2$

so the wanted reaction is (1/2) times that so

$$K = K_{A.11}^{1/2} = \sqrt{\exp(-2.217)} = \sqrt{0.108935} = 0.33$$

or

$$\ln K = 0.5 \ln K_{A.11} = 0.5\,(-2.217) = -1.1085$$

$$K = \exp(-1.1085) = 0.33$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.27

Plot to scale the values of ln *K* versus 1/*T* for the reaction $2\,CO_2 \Leftrightarrow 2\,CO + O_2$. Write an equation for ln *K* as a function of temperature.

$$2\,CO_2 \Leftrightarrow 2\,CO + 1\,O_2$$

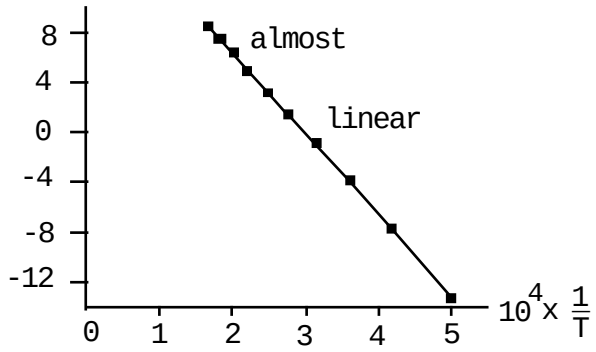
T(K)	$10^4 \times \frac{1}{T}$	ln K	T(K)	$10^4 \times \frac{1}{T}$	ln K
2000	5.000	-13.266	4000	2.500	3.204
2400	4.167	-7.715	4500	2.222	4.985
2800	3.571	-3.781	5000	2.000	6.397
3200	3.125	-0.853	5500	1.818	7.542
3600	2.778	1.408	6000	1.667	8.488

For the range below ~ 5000 K,

$\ln K \approx A + B/T$

Using values at 2000 K & 5000 K

A = 19.5056
B = -65 543 K



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.28

Consider the reaction $2\,CO_2 \Leftrightarrow 2\,CO + O_2$ obtained after heating 1 kmol CO_2 to 3000 K. Find the equilibrium constant from the shift in Gibbs function and verify its value with the entry in Table A.11. What is the mole fraction of CO at 3000 K, 100 kPa?

From Table A.9 we get:

$\Delta\bar{h}_{CO} = 93\,504$ $\quad \bar{h}^0_{f\,CO} = -110\,527$ $\quad \bar{s}_{CO} = 273.607$

$\Delta\bar{h}_{CO_2} = 152\,853$ $\quad \bar{h}^0_{f\,CO_2} = -393\,522$ $\quad \bar{s}_{CO_2} = 334.17$

$\Delta\bar{h}_{O_2} = 98\,013$ $\quad \bar{s}_{O_2} = 284.466$

$$\Delta G^0 = \Delta H - T\Delta S = 2\,H_{CO} + H_{O_2} - 2\,H_{CO_2} - T\,(2\bar{s}_{CO} + \bar{s}_{O_2} - 2\bar{s}_{CO_2})$$

$$= 2\,(93\,504 - 110\,527) + 98\,013 + 0 - 2(152\,853 - 393\,522)$$

$$-3000(2\times 273.607 + 284.466 - 2\times 334.17) = 55\,285$$

$$\ln K = -\Delta G^0/\bar{R}T = -55\,285/\,(8.31451\times 3000) = -2.2164$$

Table A.11 $\ln K = -2.217$ OK

At 3000 K,

$\ln K = -2.217$

$K = 0.108935$

	$2\,CO_2 \Leftrightarrow$	$2\,CO$	$+\,1\,O_2$
Initial	1	0	0
Change	-2z	+2z	+z
Equil.	1-2z	2z	z

We have $P = P^o = 0.1$ MPa, and $n_{tot} = 1 + z$, so from Eq.14.29

$$K = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P}{P^0}\right) = \left(\frac{2z}{1 - 2z}\right)^2 \left(\frac{z}{1 + z}\right)(1) = 0.108935\ ;$$

$$4\,z^3 = 0.108935\,(1 - 2z)^2(1 + z) \quad \Rightarrow \quad z = 0.22$$

$$y_{CO} = 2z / (1 + z) = \mathbf{0.36}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.29

Carbon dioxide is heated at 100 kPa. What should the temperature be to see a mole fraction of CO as 0.25? For that temperature, what will the mole fraction of CO be if the pressure is 200 kPa?

	$2\ CO_2 \Leftrightarrow$	$2\ CO$	$+\ 1\ O_2$
Initial	1	0	0
Change	-2z	+2z	+z
Equil.	1-2z	2z	z

We have $P = P^o = 0.1$ MPa, and $n_{tot} = 1 + z$, so from Eq.14.29

$$y_{CO} = \frac{2z}{1+z} = 0.25 \quad => \quad z = 1/7$$

$$K = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P}{P^0}\right) = \left(\frac{2z}{1-2z}\right)^2 \left(\frac{z}{1+z}\right)(1) = \left(\frac{2}{7-2}\right)^2 \left(\frac{1}{7+1}\right) = 0.02$$

$\ln K = -3.912$ from A.11 **T = 2785 K**

$$K = 0.02 = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P}{P^0}\right) = \left(\frac{2z}{1-2z}\right)^2 \left(\frac{z}{1+z}\right)(2) \quad =>$$

$$z^3 = 0.0025\,(1-2z)^2(1+z) \quad => \quad z = 0.11776$$

$$y_{CO} = \frac{2z}{1+z} = \mathbf{0.2107}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.30

Assume a diatomic gas like O_2 or N_2 dissociate at a pressure different from P_o. Find an expression for the fraction of the original gas that has dissociated at any T assuming equilibrium.

Look at initially 1 mol Oxygen and shift reaction with x

$$O_2 \Leftrightarrow 2\,O$$

Species	O_2	O	
Initial	1	0	
Change	–x	2x	
Equil.	1–x	2x	$n_{tot} = 1 - x + 2x = 1 + x$

$$y_O = \frac{2x}{1+x} \quad \text{and} \quad y_{O2} = \frac{1-x}{1+x}$$

Substitute this into the equilibrium equation as

$$K_T = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{4x^2}{(1+x)^2} \frac{1+x}{1-x} \left(\frac{P}{P_o}\right) = \frac{4x^2}{1-x^2} \left(\frac{P}{P_o}\right)$$

Now solve for x as

$$x^2 = (1 - x^2)\ \frac{K_T P_o}{4P}$$

$$x = \sqrt{\frac{K_T}{4(P/P_o) + K_T}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.31

Hydrogen gas is heated from room temperature to 4000 K, 500 kPa, at which state the diatomic species has partially dissociated to the monatomic form. Determine the equilibrium composition at this state.

$H_2 \Leftrightarrow 2\ H$ Equil. $n_{H2} = 1 - x$

$-x \quad +2x$ $n_H = 0 + 2x$

$n = 1 + x$

$$K = \frac{(2x)^2}{(1-x)(1+x)} \left(\frac{P}{P^0}\right)^{2-1}$$ at 4000 K: $\ln K = 0.934 \Rightarrow K = 2.545$

$$\frac{2.545}{4 \times (500/100)} = 0.127\ 25 = \frac{x^2}{1-x^2}$$ Solving, $x = 0.3360$

$n_{H2} = 0.664, \quad n_H = 0.672, \quad n_{tot} = 1.336$

$y_{H2} = 0.497, \quad y_H = 0.503$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.32

Consider the dissociation of oxygen, $O_2 \Leftrightarrow 2\ O$, starting with 1 kmol oxygen at 298 K and heating it at constant pressure 100 kPa. At which temperature will we reach a concentration of monatomic oxygen of 10%?

Look at initially 1 mol Oxygen and shift reaction with x

$$O_2 \Leftrightarrow 2\ O$$

Species	O_2	O	
Initial	1	0	
Change	-x	2x	
Equil.	1-x	2x	$n_{tot} = 1 - x + 2x = 1 + x$

$$y_O = \frac{2x}{1 + x} = 0.1 \quad \Rightarrow \quad x = 0.1/(2 - 0.1) = 0.0526, \quad y_{O2} = 0.9$$

$$K = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{0.1^2}{0.9}\, 1 = 0.01111 \qquad \Rightarrow \qquad \ln K = -4.4998$$

Now look in Table A.11: T = **2980 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.33

Redo Problem 14.32 for a total pressure of 40 kPa.

Look at initially 1 mol Oxygen and shift reaction with x

$$O_2 \Leftrightarrow 2\,O$$

Species	O_2	O	
Initial	1	0	
Change	-x	2x	
Equil.	1-x	2x	$n_{tot} = 1 - x + 2x = 1 + x$

$$y_O = \frac{2x}{1+x} = 0.1 \quad \Rightarrow \quad x = 0.1/(2 - 0.1) = 0.0526, \quad y_{O2} = 0.9$$

$$K = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{0.1^2}{0.9}\, 0.4 = 0.004444 \quad \Rightarrow \ln K = -5.4161$$

Now look in Table A.11: T = **2856 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.34

Redo Problem 14.32, but start with 1 kmol oxygen and 1 kmol helium at 298 K, 100 kPa.

Look at initially 1 mol Oxygen and shift reaction with x

$$O_2 \Leftrightarrow 2\,O$$

Species	O_2	O	He	
Initial	1	0	1	
Change	-x	2x		
Equil.	1-x	2x	1	$n_{tot} = 1 - x + 2x + 1 = 2 + x$

$$y_O = \frac{2x}{2 + x} = 0.1 \quad \Rightarrow \quad x = 0.2/(2 - 0.1) = 0.10526,$$

$$y_{O2} = (1 - x)/(2 + x) = 0.425$$

$$K = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{0.1^2}{0.425}\, 1 = 0.023529 \quad \Rightarrow \ln K = -3.7495$$

Now look in Table A.11: T = **3094 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.35

Calculate the equilibrium constant for the reaction: $2CO_2 \Leftrightarrow 2CO + O_2$ at 3000 K using values from Table A.9 and compare the result to Table A.11.

From Table A.9 we get:

	kJ/kmol	kJ/kmol	kJ/kmol K
CO	$\Delta\bar{h}_{CO} = 93\,504$	$\bar{h}^o_{f\ CO} = -110\,527$	$\bar{s}_{CO} = 273.607$
CO_2	$\Delta\bar{h}_{CO_2} = 152\,853$	$\bar{h}^o_{f\ CO_2} = -393\,522$	$\bar{s}_{CO_2} = 334.17$
O_2	$\Delta\bar{h}_{O_2} = 98\,013$	$\bar{h}^o_{f\ O_2} = 0$	$\bar{s}_{O_2} = 284.466$

$$\Delta G^0 = \Delta H - T\Delta S = 2\,H_{CO} + H_{O_2} - 2\,H_{CO_2} - T\,(2\bar{s}_{CO} + \bar{s}_{O_2} - 2\bar{s}_{CO_2})$$

$$= 2\,(93\,504 - 110\,527) + 98\,013 + 0 - 2(152\,853 - 393\,522)$$

$$-3000(2\times 273.607 + 284.466 - 2\times 334.17) = 55\,285 \text{ kJ/kmol}$$

$$\ln K = -\Delta G^0/\bar{R}T = -55\,285/\,(8.31451\times 3000) = -2.2164$$

Table A.11 ln K = -2.217 OK

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.36

Find the equilibrium constant for: $CO + 1/2O_2 \Leftrightarrow CO_2$ at 2200 K using Table A.11

The elementary reaction in A.11 is: $2\,CO_2 \Leftrightarrow 2CO + O_2$

The wanted reaction is therefore (–0.5) times that so

$$K = K_{A.11}^{-1/2} = 1 / \sqrt{\exp(-10.232)} = 1 / \sqrt{0.000036} = 166.67$$

or

$$\ln K = -0.5 \ln K_{A.11} = -0.5\,(-10.232) = 5.116$$

$$K = \exp(5.116) = 166.67$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.37

Pure oxygen is heated from 25°C to 3200 K in an steady flow process at a constant pressure of 200 kPa. Find the exit composition and the heat transfer.

The only reaction will be the dissociation of the oxygen

$O_2 \Leftrightarrow 2O$; From A.11: K(3200) = exp(-3.069) = 0.046467

Look at initially 1 mol Oxygen and shift reaction with x

$n_{O2} = 1 - x$; $n_O = 2x$; $n_{tot} = 1 + x$; $y_i = n_i/n_{tot}$

$$K = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{4x^2}{(1+x)^2} \frac{1+x}{1-x} 2 = \frac{8x^2}{1-x^2}$$

$$x^2 = \frac{K/8}{1 + K/8} \quad \Rightarrow \quad x = 0.07599;$$

$$y_{0_2} = \frac{1-x}{1+x} = \mathbf{0.859}; \quad y_0 = 1 - y_{0_2} = \mathbf{0.141}$$

$$\bar{q} = n_{0_2 ex} \bar{h}_{0_2 ex} + n_{0ex} \bar{h}_{Oex} - \bar{h}_{0_2 in} = (1+x)(y_{0_2} \bar{h}_{0_2} + y_0 \bar{h}_O) - 0$$

$\bar{h}_{0_2} = 106\,022$ kJ/kmol; $\bar{h}_O = 249\,170 + 60\,767 = 309\,937$ kJ/kmol

$\Rightarrow \quad \bar{q} = 145\,015$ kJ/kmol O_2

$q = \bar{q}/32 =$ **4532 kJ/kg** (= 3316.5 if no reaction)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.38

Nitrogen gas, N_2, is heated to 4000 K, 10 kPa. What fraction of the N_2 is dissociated to N at this state?

$N_2 \iff 2\,N$ @ T = 4000 K, lnK = -12.671

Initial	1	0	$K = 3.14\text{x}10^{-6}$
Change	-x	2x	
Equil.	1-x	2x	$n_{tot} = 1 - x + 2x = 1 + x$

$$y_{N2} = \frac{1 - x}{1 + x}, \qquad y_N = \frac{2x}{1 + x}$$

$$K = \frac{y_N^2}{y_{N2}} \left(\frac{P}{P_o}\right)^{2-1}; \quad \Rightarrow \quad 3.14\text{x}10^{-6} = \frac{4x^2}{1 - x^2}\left(\frac{10}{100}\right) \quad \Rightarrow \quad x = 0.0028$$

$$y_{N2} = \frac{1 - x}{1 + x} = \mathbf{0.9944}, \qquad y_N = \frac{2x}{1 + x} = \mathbf{0.0056}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.40

One kilomole Ar and one kilomole O_2 are heated up at a constant pressure of 100 kPa to 3200 K, where it comes to equilibrium. Find the final mole fractions for Ar, O_2, and O.

The only equilibrium reaction listed in the book is dissociation of O_2.

So assuming that, we see in Table A.11: $\ln(K) = -3.072$

$$Ar + O_2 \Rightarrow Ar + (1 - x)\, O_2 + 2x\, O$$

The atom balance already shown in above equation can also be done as

Species	Ar	O_2	O
Start	1	1	0
Change	0	-x	2x
Total	1	1-x	2x

The total number of moles is $n_{tot} = 1 + 1\text{-}x + 2x = 2 + x$ so

$$y_{Ar} = 1/(2 + x); \quad y_{O_2} = 1 - x/(2 + x); \quad y_O = 2x/(2 + x)$$

and the definition of the equilibrium constant ($P_{tot} = P_o$) becomes

$$K = e^{-3.072} = 0.04633 = \frac{y_O^2}{y_{0_2}} = \frac{4x^2}{(2 + x)(1 - x)}$$

The equation to solve becomes from the last expression

$$(K + 4)x^2 + Kx - 2K = 0$$

If that is solved we get

$$x = -0.0057 \pm 0.1514 = 0.1457; \qquad x \text{ must be positive}$$

$$y_O = 0.1358; \quad y_{0_2} = 0.3981; \quad y_{Ar} = 0.4661$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.41

Air (assumed to be 79% nitrogen and 21% oxygen) is heated in a steady state process at a constant pressure of 100 kPa, and some NO is formed. At what temperature will the mole fraction of NO be 0.001?

$0.79\ N_2 + 0.21\ O_2$ heated at 100 kPa, forms NO

$N_2 + O_2 \Leftrightarrow 2\ NO$

$-x \quad -x \quad +2x$

$n_{N2} = 0.79 - x$

$n_{O2} = 0.21 - x$

$n_{NO} = 0 + 2x$

$n_{tot} = 1.0$

At exit, $y_{NO} = 0.001 = \dfrac{2x}{1.0} \quad \Rightarrow \quad x = 0.0005$

$\Rightarrow n_{N2} = 0.7895,\ n_{O2} = 0.2095$

$$K = \frac{y_{NO}^2}{y_{N2} y_{O2}} \left(\frac{P}{P^0}\right)^0 = \frac{10^{-6}}{0.7895 \times 0.2095} = 6.046 \times 10^{-6} \quad \text{or} \quad \ln K = -12.016$$

From Table A.11, T = **1444 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.42

Pure oxygen is heated from 25°C, 100 kPa to 3200 K in a constant volume container. Find the final pressure, composition, and the heat transfer.

As oxygen is heated it dissociates

$$O_2 \Leftrightarrow 2O \qquad \ln K_{eq} = -3.069 \quad \text{from table A.11}$$

C. V. Heater: $U_2 - U_1 = {}_1Q_2 = H_2 - H_1 - P_2v + P_1v$

Per mole O_2: $\quad {}_1\bar{q}_2 = \bar{h}_2 - \bar{h}_1 + \bar{R}[T_1 - (n_2/n_1)T_2]$

Shift x in reaction 1 to have final composition: $(1 - x)O_2 + 2xO$

$n_1 = 1 \qquad n_2 = 1 - x + 2x = 1 + x$

$y_{O_2} = (1 - x)/(1 + x)$; $\quad y_O = 2x/(1 + x)$

Ideal gas and $V_2 = V_1 \Rightarrow P_2 = P_1 n_2 T_2/n_1 T_1 \quad \Rightarrow \quad P_2/P_o = (1 + x)T_2/T_1$

Substitute the molefractions and the pressure into the equilibrium equation

$$K_{eq} = e^{-3.069} = \frac{y_O^2}{y_{O_2}} \left(\frac{P_2}{P_o}\right) = \left(\frac{2x}{1 + x}\right)^2 \left(\frac{1 + x}{1 - x}\right) \left(\frac{1 + x}{1}\right) \left(\frac{T_2}{T_1}\right)$$

$$\Rightarrow \quad \frac{4x^2}{1 - x} = \frac{T_1}{T_2} e^{-3.069} = 0.00433 \quad \Rightarrow \quad x = 0.0324$$

The final pressure is then

$$P_2 = P_o(1 + x)\frac{T_2}{T_1} = 100\ (1 + 0.0324) \times \frac{3200}{298.2} = \mathbf{1108\ kPa}$$

$(n_{O_2}) = 0.9676, \quad (n_O) = 0.0648, \quad n_2 = 1.0324$

$${}_1\bar{q}_2 = 0.9676 \times 106022 + 0.0648\ (249170 + 60767) - 0$$
$$+ 8.3145\ (298.15 - 1.0324 \times 3200) = \mathbf{97681\ kJ/kmol O_2}$$

$$y_{O_2} = \frac{0.9676}{1.0324} = \mathbf{0.937}; \qquad y_O = \frac{0.0648}{1.0324} = \mathbf{0.0628}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.43

Find the equilibrium constant for the reaction $2NO + O_2 \Leftrightarrow 2NO_2$ from the elementary reactions in Table A.11 to answer which of the nitrogen oxides, NO or NO_2, is the more stable at ambient conditions? What about at 2000 K?

$$2\,NO + O_2 \Leftrightarrow 2\,NO_2 \quad (1)$$

But $$N_2 + O_2 \Leftrightarrow 2\,NO \quad (2)$$

$$N_2 + 2\,O_2 \Leftrightarrow 2\,NO_2 \quad (3)$$

Reaction 1 = Reaction 3 - Reaction 2

$$\Rightarrow \quad \Delta G^0_1 = \Delta G^0_3 - \Delta G^0_2 \quad => \quad \ln K_1 = \ln K_3 - \ln K_2$$

At 25 ^oC, from Table A.11: $\ln K_1 = -41.355 - (-69.868) = +28.513$

or $K_1 = 2.416 \times 10^{12}$

an extremely large number, which means reaction 1 tends to go very strongly from left to right.

At 2000 K: $\ln K_1 = -19.136 - (-7.825) = -11.311$ or $K_1 = 1.224 \times 10^{-5}$

meaning that reaction 1 tends to go quite strongly from right to left.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.44

Assume the equilibrium mole fractions of oxygen and nitrogen are close to those in air, find the equilibrium mole fraction for NO at 3000 K, 500 kPa disregarding dissociations.

Assume the simple reaction to make NO as:

N_2 + O_2 ⇔ 2 NO	Ar	$n_{N2} = 0.78 - x$
0.78 0.21 0	0.01	$n_{O2} = 0.21 - x$
-x -x +2x		$n_{NO} = 2x$, $n_{ar} = 0.01$
0.78–x 0.21–x 2x	0.01	$n_{tot} = 1.0$

From A.11 at 3000 K, $\ln K = -4.205$, $K = 0.014921$

$$K = \frac{4x^2}{(0.78 - x)(0.21 - x)} \left(\frac{P}{P^0}\right)^0 \quad \Rightarrow$$

$$\frac{x^2}{(0.78 - x)(0.21 - x)} = \frac{0.014921}{4} = 0.00373 \quad \text{and} \quad 0 < x < 0.21$$

Solve for x: $x = 0.0230$ ⇨ $y_{NO} = \frac{2x}{1.0} = \mathbf{0.046}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.45

The combustion products from burning pentane, C_5H_{12}, with pure oxygen in a stoichiometric ratio exists at 2400 K, 100 kPa. Consider the dissociation of only CO_2 and find the equilibrium mole fraction of CO.

$$C_5H_{12} + 8\ O_2 \rightarrow 5\ CO_2 + 6\ H_2O$$

At 2400 K,

ln K = -7.715

$K = 4.461 \times 10^{-4}$

$2\ CO_2 \Leftrightarrow 2\ CO + 1\ O_2$

Initial	5	0	0
Change	-2z	+2z	+z
Equil.	5-2z	2z	z

Assuming $P = P^o = 0.1$ MPa, and $n_{tot} = 5 + z + 6 = 11 + z$

$$K = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P}{P^0}\right) = \left(\frac{2z}{5 - 2z}\right)^2 \left(\frac{z}{11 + z}\right)(1) = 4.461 \times 10^{-4}\ ;$$

Trial & Error (compute LHS for various values of z): z = 0.291

$n_{CO_2} = 4.418$; $n_{CO} = 0.582$; $n_{O_2} = 0.291$ => $y_{CO} =$ **0.0515**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.46

A mixture flows with 2 kmol/s CO_2, 1 kmol/s argon and 1 kmol/s CO at 298 K and it is heated to 3000 K at constant 100 kPa. Assume the dissociation of carbon dioxide is the only equilibrium process to be considered. Find the exit equilibrium composition and the heat transfer rate.

Reaction	$2\,CO_2$	$\Leftrightarrow$	$2\,CO$	+	O_2	Ar
initial	2		1		0	1
change	-2x		+2x		+x	
equil.	2 - 2x		1 + 2x		x	1

From Table A.11:

$$K = \exp(-2.217) = 0.108935 = \frac{y_{CO}^2\, y_{O2}}{y_{CO2}^2}\left(\frac{P}{P_o}\right)^{3-2}$$

$$= \frac{(1+2x)^2}{(4+x)^2}\,\frac{x}{4+x}\,\frac{(4+x)^2}{(2-2x)^2}\,(1)^1 = \frac{x}{4}\,\frac{(1+2x)^2}{4+x}\,\frac{1}{(1-x)^2}$$

then

$$0.43574\,(4+x)\,(1-x)^2 = x\,(1+2x)^2$$

trial and error solution gives x = 0.32136

The outlet has: $1.35728\,CO_2 + 1.64272\,CO + 1\,Ar + 0.32136\,O_2$

Energy equation gives from Table A.9 and A.5 (for argon $C_p\Delta T$)

$$\dot{Q} = \sum \dot{n}_{ex}\,\bar{h}_{ex} - \sum \dot{n}_{in}\,\bar{h}_{in}$$

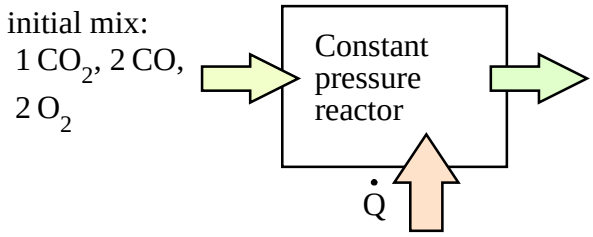
$$= 1.35728\,(152853 - 393522) + 1.64272\,(93504 - 110527)$$
$$+ 1\,(39.948 \times 0.52 \times (3000 - 298)) + 0.32136\,(98013)$$
$$- 2\,(-393522) - 1(-110527) - 1\,(0)$$

$$= \mathbf{630\ 578\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.47

A mixture of 1 kmol carbon dioxide, 2 kmol carbon monoxide, and 2 kmol oxygen, at 25°C, 150 kPa, is heated in a constant pressure steady state process to 3000 K. Assuming that only these same substances are present in the exiting chemical equilibrium mixture, determine the composition of that mixture.



Reaction	$2\,CO_2$	$\Leftrightarrow$	$2\,CO$	+	O_2
initial	1		2		2
change	-2x		+2x		+x
equil.	(1 - 2x)		(2 + 2x)		(2 + x)

$n_{tot} = 1 - 2x + 2 + 2x + 2 + x = 5 + x$ so $y = n/ n_{tot}$

From A.11 at 3000 K: $K = \exp(-2.217) = 0.108935$

For each $n > 0$ $\Rightarrow$ $-1 < x < +\frac{1}{2}$

$$K = \frac{y_{CO}^2 y_{O2}}{y_{CO2}^2}\left(\frac{P}{P^0}\right)^1 = 4\left(\frac{1+x}{1-2x}\right)^2\left(\frac{2+x}{5+x}\right)\left(\frac{150}{100}\right) = 0.108935$$

or $\left(\frac{1+x}{1-2x}\right)^2\left(\frac{2+x}{5+x}\right) = 0.018\,156$, Trial & error: $x = -0.521$

$n_{CO2} = 2.042$ $n_{O2} = 1.479$
$n_{CO} = 0.958$ $n_{tot} = 4.479$

$y_{CO2} = 0.4559$
$y_{CO} = 0.2139$
$y_{O2} = 0.3302$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.48

Acetylene gas Acetylene gas, C_2H_2, is burned with stoichiometric air in a torch. The reactants are supplied at the reference conditions P_0, T_0. The products come out from the flame at 2800 K after a small heat loss by radiation. Consider the dissociation of CO_2 into CO and O_2 and no others. Find the equilibrium composition of the products. Are there any other reactions that should be considered?

Combustion: $C_2H_2 + 2.5\,(O_2 + 3.76N_2) \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$

At 2800 K, $\ln K = -3.781$, $K = 0.0228$

	$2\,CO_2 \Leftrightarrow 2\,CO + 1\,O_2$			H_2O	N_2
Initial	2	0	0	1	9.4
Change	-2z	+2z	+z	0	0
Equil.	2-2z	2z	z	1	9.4

Assuming $P = P^o = 0.1$ MPa, and $n_{tot} = 2 + z + 1 + 9.4 = 12.4 + z$

$$K = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P}{P^0}\right) = \left(\frac{2z}{2 - 2z}\right)^2 \left(\frac{z}{12.4 + z}\right)(1) = 0.0228;$$

Solve: $z^3 = 0.0228\,(1 - z)^2(12.4 + z) \quad \Rightarrow \quad z = 0.4472$

$$y_{CO} = \frac{2z}{12.4 + z} = \mathbf{0.0696};\quad y_{CO2} = \frac{2 - 2z}{12.4 + z} = \mathbf{0.086};\quad y_{O2} = \frac{z}{12.4 + z} = \mathbf{0.0348}$$

$$y_{H2O} = \frac{1}{12.4 + z} = \mathbf{0.0778};\quad y_{N2} = \frac{9.4}{12.4 + z} = \mathbf{0.7317}$$

Looking in A.11 there will be no dissociation of nitrogen and only a small dissociation of water and oxygen which could be included.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.49

Consider combustion of methane with pure oxygen forming carbon dioxide and water as the products. Find the equilibrium constant for the reaction at 1000 K. Use an average heat capacity of Cp = 52 kJ/kmol K for the fuel and Table A.9 for the other components.

For the reaction equation,

$$CH_4 + 2\,O_2 \Leftrightarrow CO_2 + 2\,H_2O$$

At 1000 K from Table A.9 and A.10 for the fuel at 298 K

$$\Delta H^0_{1000\,K} = 1(-393\,522 + 33\,397) + 2(-241\,826 + 26\,000) - 1[-74\,873 + 52(1000 - 298.2)] - 2(0 + 22\,703)$$
$$= -798\,804 \text{ kJ/kmol}$$

$$\Delta S^0_{1000\,K} = 1\times 269.299 + 2\times 232.739 - 1\left(186.251 + \ln\frac{1000}{298.2}\right) - 2\times 243.579$$
$$= 487.158 \text{ kJ/kmol K}$$

$$\Delta G^0_{1000\,K} = \Delta H^0_{1000\,K} - T\ \Delta S^0_{1000\,K}$$
$$= -798\,804 - 1000 \times 487.158 = -1\,285\,962 \text{ kJ/kmol}$$

$$\ln K = -\frac{\Delta G^0}{\bar{R}T} = \frac{+1\,285\,962}{8.3145\times 1000} = +154.665 \quad , \quad \mathbf{K = 1.4796\ E\ 67}$$

This means the reaction is shifted totally to the right.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.50

Water from the combustion of hydrogen and pure oxygen is at 3800 K and 50 kPa. Assume we only have H_2O, O_2 and H_2 as gases find the equilibrium composition.

With only the given components we have the reaction

$$2\,H_2O \quad \Leftrightarrow \quad 2H_2 + O_2$$

which at 3800 K has an equilibrium constant from A.11 as $\ln K = -1.906$

Assume we start with 2 kmol water and let it dissociate x to the left then

Species	H_2O	H_2	O_2	
Initial	2	0	0	
Change	-2x	2x	x	
Final	2 – 2x	2x	x	Tot: 2 + x

Then we have

$$K = \exp(-1.906) = \frac{y_{H_2}^2\, y_{O_2}}{y_{H_2O}^2} \left(\frac{P}{P^0}\right)^{2+1-2} = \frac{\left(\frac{2x}{2+x}\right)^2 \frac{x}{2+x}}{\left(\frac{2-2x}{2+x}\right)^2} \frac{50}{100}$$

which reduces to

$$0.148674 = \frac{1}{(1-x)^2} \frac{4x^3}{2+x} \frac{1}{4} \frac{1}{2} \quad \text{or} \quad x^3 = 0.297348\ (1-x)^2\,(2+x)$$

Trial and error to solve for x = 0.54 then the concentrations are

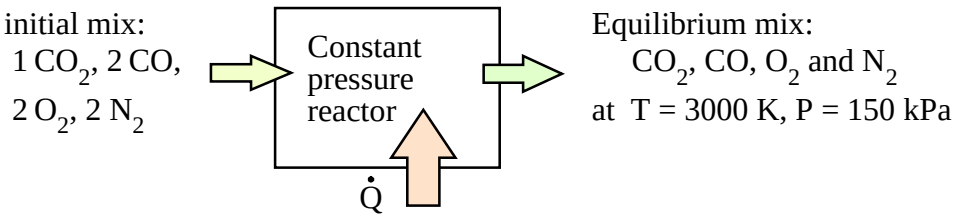
$$y_{H2O} = \frac{2-2x}{2+x} = 0.362; \quad y_{O2} = \frac{x}{2+x} = 0.213; \quad y_{H2} = \frac{2x}{2+x} = 0.425$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.51

Repeat problem 14.47 for an initial mixture that also includes 2 kmol of nitrogen, which does not dissociate during the process.

This problem has a dilution of the reactant with nitrogen.



Reaction	$2\,CO_2$	$\Leftrightarrow$	$2\,CO$	+	O_2
initial	1		2		2
change	-2x		+2x		+x
equil.	(1-2x)		(2+2x)		(2+x)

From A.11 at 3000 K: $K = \exp(-2.217) = 0.108935$

For each $n > 0 \quad \Rightarrow \quad -1 < x < +\frac{1}{2}$

Equilibrium: $n_{CO2} = (1 - 2x)$, $n_{CO} = (2 + 2x)$, $n_{O2} = (2 + x)$,

$n_{N2} = 2$ so then $n_{tot} = 7 + x$

$$K = \frac{y_{CO}^2 y_{O2}}{y_{CO2}^2} \left(\frac{P}{P^0}\right)^1 = 4 \left(\frac{1 + x}{1 - 2x}\right)^2 \left(\frac{2 + x}{7 + x}\right) \left(\frac{150}{100}\right) = 0.108935$$

or $\left(\frac{1 + x}{1 - 2x}\right)^2 \left(\frac{2 + x}{7 + x}\right) = 0.018167$ Trial & error: $x = -0.464$

$$\left.\begin{array}{ll} n_{CO2} = 1.928 & n_{O2} = 1.536 \\ n_{CO} = 1.072 & n_{N2} = 2.0 \\ & n_{TOT} = 6.536 \end{array}\right\} \quad \left\{\begin{array}{ll} y_{CO2} = 0.295 & y_{O2} = 0.235 \\ y_{CO} = 0.164 & y_{N2} = 0.306 \end{array}\right.$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.52

Catalytic gas generators are frequently used to decompose a liquid, providing a desired gas mixture (spacecraft control systems, fuel cell gas supply, and so forth). Consider feeding pure liquid hydrazine, N_2H_4, to a gas generator, from which exits a gas mixture of N_2, H_2, and NH_3 in chemical equilibrium at 100°C, 350 kPa. Calculate the mole fractions of the species in the equilibrium mixture.

Initially, $\quad 2\,N_2H_4 \rightarrow 1\,N_2 + 1\,H_2 + 2\,NH_3$

Reaction:	N_2	+	$3\,H_2$	$\Leftrightarrow$	$2\,NH_3$	
initial	1		1		2	
change	-x		-3x		+2x	
equil.	(1-x)		(1-3x)		(2+2x)	$n_{TOTAL} = (4-2x)$

$$K = \frac{y_{NH3}^2}{y_{N2}y_{H2}^3}\left(\frac{P}{P^0}\right)^{-2} = \frac{(2+2x)^2(4-2x)^2}{(1-x)(1-3x)^3}\left(\frac{350}{100}\right)^{-2}$$

At 100 °C = 373.2 K, for NH_3 use A.5 $\quad \bar{C}_{P0} = 17.03\times 2.130 = 36.276$

$$\bar{h}^0_{NH3} = -45\,720 + 36.276(373.2 - 298.2) = -42\,999 \text{ kJ/kmol}$$

$$\bar{s}^0_{NH3} = 192.572 + 36.276 \ln\frac{373.2}{298.2} = 200.71 \text{ kJ/kmol K}$$

Using A.9,

$$\Delta H^0_{100\,C} = 2(-42\,999) - 1(0+2188) - 3(0+2179) = -94\,723 \text{ kJ}$$

$$\Delta S^0_{100\,C} = 2(200.711) - 1(198.155) - 3(137.196) = -208.321 \text{ kJ/K}$$

$$\Delta G^0_{100\,C} = \Delta H^0 - T\Delta S^0 = -94\,723 - 373.2(-208.321) = -16\,978 \text{ kJ}$$

$$\ln K = -\frac{\Delta G^0}{\bar{R}T} = \frac{+16\,978}{8.3145\times 373.2} = 5.4716 \quad \Rightarrow \quad K = 237.84$$

Therefore,

$$\left[\frac{(1+x)(2-x)}{(1-3x)}\right]^2 \frac{1}{(1-x)(1-3x)} = \frac{237.84\times 3.5^2}{16} = 182.096$$

By trial and error, x = 0.226

$$\left.\begin{matrix} n_{N2} = 0.774 & n_{NH3} = 2.452 \\ n_{H2} = 0.322 & n_{TOT} = 3.518 \end{matrix}\right\} \quad \begin{cases} y_{N2} = 0.2181 \\ y_{H2} = 0.0908 \\ y_{NH3} = 0.6911 \end{cases}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.53

Complete combustion of hydrogen and pure oxygen in a stoichiometric ratio at P_o, T_o to form water would result in a computed adiabatic flame temperature of 4990 K for a steady state setup. How should the adiabatic flame temperature be found if the equilibrium reaction $2H_2 + O_2 \Leftrightarrow 2H_2O$ is considered? Disregard all other possible reactions (dissociations) and show the final equation(s) to be solved.

$2H_2 + O_2 \Leftrightarrow 2H_2O$

Species	H_2	O_2	H_2O
Initial	2	1	0
Shift	–2x	–x	2x
Final	2 – 2x	1 –x	2x

$$K_{eq} = \frac{y_{H_2O}^2}{y_{H_2}^2 y_{O_2}} \left(\frac{P}{P^0}\right)^{-1}, \qquad n_{tot} = 2 - 2x + 1 - x + 2x = 3 - x$$

Energy Eq.: $H_P = H_R = H_P^o + \Delta H_P = H_R^o = 0$

$$H_P = (1 - x)(2\Delta\bar{h}_{H_2} + \Delta\bar{h}_{O_2}) + 2x(\bar{h}_{fH2O}^o + \Delta\bar{h}_{H2O}) = 0 \qquad (1)$$

Equilibrium constant:

$$K_{eq} = \frac{4x^2}{(3-x)^2} \frac{(3 - x)^2}{(2 - 2x)^2} \frac{3 - x}{1 - x} = \frac{x^2(3 - x)}{(1 - x)^3} = K_T \qquad (2)$$

A.10: $\bar{h}_{fH2O}^o = -241\,826$ kJ/kmol; A.11: $\ln(K_T)$

A.9: $\Delta\bar{h}_{H_2}(T)$, $\Delta\bar{h}_{O_2}(T)$, $\Delta\bar{h}_{H_2O}(T)$,

Trial and error (solve for x, T) using Eqs. (1) and (2).

Guess T = 3600 K: K = exp(1.996) = 7.35956, x = 0.53986

$H_P = (1 - 0.53986)(2 \times 111\,367 + 122\,245)$

$+ 2 \times 0.53986 \times (-241\,826 + 160\,484) = 70\,912$ high

Guess T = 3400 K: K = exp(3.128) = 22.8283, x = 0.648723

$H_P = (1 - 0.648723)(2 \times 103\,736 + 114\,101)$

$+ 2 \times 0.648723 \times (-241\,826 + 149\,073) = -7381$ low

Now do a linear interpolation to get $H_P = 0$:

$T = 3400 + 200 \times 7381/(70\,912 + 7381) =$ **3419 K**, K = 20.50

x = 0.63905, $y_{O_2} = 0.153$; $y_{H_2} = 0.306$; $y_{H_2O} = 0.541$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.54

Consider the water gas reaction in Example 14.4. Find the equilibrium constant at 500, 1000, 1200 and 1400 K. What can you infer from the result?

As in Example 14.4, III $H_2 + CO_2 \Leftrightarrow H_2O + CO$

I $2\,CO_2 \Leftrightarrow 2\,CO + O_2$

II $2\,H_2O \Leftrightarrow 2\,H_2 + O_2$

Then, $\ln K_{III} = 0.5\,(\ln K_I - \ln K_{II})$

At 500 K, $\ln K_{III} = 0.5\,(-115.234 - (-105.385)) = -4.9245$,
$K = 0.007\,266$

At 1000 K, $\ln K_{III} = 0.5\,(-47.052 - (-46.321)) = -0.3655$,
$K = 0.693\,85$

At 1200 K, $\ln K_{III} = 0.5\,(-35.736 - (-36.363)) = +0.3135$,
$K = 1.3682$

At 1400 K, $\ln K_{III} = 0.5\,(-27.679 - (-29.222)) = +0.7715$,
$K = 2.163$

It is seen that at lower temperature, reaction III tends to go strongly from right to left, but as the temperature increases, the reaction tends to go more strongly from left to right. If the goal of the reaction is to produce more hydrogen, then it is desirable to operate at lower temperature.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.55

A piston/cylinder contains 0.1 kmol hydrogen and 0.1 kmol Ar gas at 25°C, 200 kPa. It is heated up in a constant pressure process so the mole fraction of atomic hydrogen is 10%. Find the final temperature and the heat transfer needed.

When gas is heated up H_2 splits partly into H as

$H_2 \Leftrightarrow 2H$ and the gas is diluted with Ar

Component	H_2	Ar	H	
Initial	0.1	0.1	0	
Shift	-x	0	2x	
Final	0.1-x	0.1	2x	Total = 0.2 + x

$y_H = 0.1 = 2x /(0.2 + x) \quad \Rightarrow \quad 2x = 0.02 + 0.1x$

$\Rightarrow \quad x = 0.010526 \quad \Rightarrow n_{tot} = 0.21053$

$y_{H2} = 0.425 = [(0.1 - x)/(0.2 + x)]; \quad y_{Ar} = 1 – rest = 0.475$

Do the equilibrium constant:

$$K(T) = \frac{y_H^2}{y_{H2}} \left(\frac{P}{P^0}\right)^{2-1} = \left(\frac{0.01}{0.425}\right) \times \left(\frac{200}{100}\right) = 0.047059$$

ln (K) = –3.056 so from Table A.11 interpolate to get T = 3110 K

To do the energy eq., we look up the enthalpies in Table A.9 at 3110 K

$h_{H2} = 92\,829.1; \quad h_H = h_f + \Delta h = 217\,999 + 58\,447.4 = 276\,445.4$

$h_{Ar} = 0 + C_p(3110 – 298.15) = 20.7863 \times (3110\text{-}298.13) = 58\,447.9$

(same as Δh for H)

Now get the total number of moles to get

$$n_H = 0.021053; \quad n_{H2} = n_{tot} \times \frac{1\text{-}x}{2+x} = 0.08947; \quad n_{Ar} = 0.1$$

Since pressure is constant W = PΔV and Q becomes differences in h

$$Q = n\Delta h = 0.08947 \times 92\,829.1 – 0 + 0.021053 \times 276\,446.4$$
$$– 0 + 0.1 \times 58\,447.9$$
$$= \mathbf{19\,970\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.56

The van't Hoff equation

$$d \ln K = \frac{\Delta H^o}{\bar{R}T^2} \, dT_p{}^o$$

relates the chemical equilibrium constant K to the enthalpy of reaction ΔH^o. From the value of K in Table A.11 for the dissociation of hydrogen at 2000 K and the value of ΔH^o calculated from Table A.9 at 2000 K use van't Hoff equation to predict the constant at 2400 K.

$$H_2 \Leftrightarrow 2H$$

$$\Delta H° = 2 \times (35\,375 + 217\,999) - 52\,942 = 453\,806 \text{ kJ/kmol}$$

$$\ln K_{2000} = -12.841;$$

Assume $\Delta H°$ is constant and integrate the Van't Hoff equation

$$\ln K_{2400} - \ln K_{2000} = \int_{2400}^{2000} \frac{\Delta H^o}{\bar{R}T^2} \, dT = -\frac{\Delta H°}{\bar{R}} \left(\frac{1}{T_{2400}} - \frac{1}{T_{2000}}\right)$$

$$\ln K_{2400} = \ln K_{2000} + \Delta H° \left(\frac{1}{T_{2400}} - \frac{1}{T_{2000}}\right) / \bar{R}$$

$$= -12.841 + 453\,806 \left(\frac{6-5}{12000}\right) / 8.31451 = -12.841 + 4.548$$

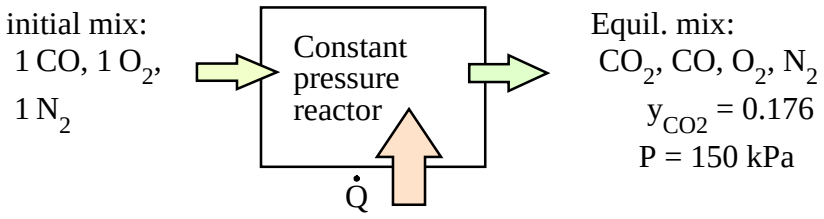
$$= -8.293$$

Table A.11 lists –8.280 ($\Delta H°$ not exactly constant)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.57

A gas mixture of 1 kmol carbon monoxide, 1 kmol nitrogen, and 1 kmol oxygen at 25°C, 150 kPa, is heated in a constant pressure process. The exit mixture can be assumed to be in chemical equilibrium with CO_2, CO, O_2, and N_2 present. The mole fraction of CO_2 at this point is 0.176. Calculate the heat transfer for the process.



reaction	$2\,CO_2$	$\Leftrightarrow$	$2\,CO$	+	O_2	also,	N_2
initial	0		1		1		1
change	+2x		-2x		-x		0
equil.	2x		(1-2x)		(1-x)		1

$$y_{CO2} = 0.176 = \frac{2x}{3\text{-}x} \quad \Rightarrow \quad x = 0.242\,65$$

$$\left.\begin{matrix} n_{CO2} = 0.4853 & n_{O2} = 0.7574 \\ n_{CO} = 0.5147 & n_{N2} = 1 \end{matrix}\right\} \left\{\begin{matrix} y_{CO2} = 0.176 \\ y_{CO} = 0.1867 \end{matrix}\right. \quad y_{O2} = 0.2747$$

$$K = \frac{y_{CO}^2 y_{O2}}{y_{CO2}^2}\left(\frac{P}{P^0}\right)^1 = \frac{0.1867^2 \times 0.2747}{0.176^2}\left(\frac{150}{100}\right) = 0.4635$$

From A.11, $T_{PROD} = 3213$ K

From A.10, $H_R = -110\,527$ kJ

$H_P = 0.4853(-393\,522 + 166\,134) + 0.5147(-110\,527 + 101\,447)$

$+ 0.7574(0 + 106\,545) + 1(0 + 100\,617)$

$= +66\,284$ kJ

$Q_{CV} = H_P - H_R = 66\,284 - (-110\,527) =$ **+176 811 kJ**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.58

A tank contains 0.1 kmol hydrogen and 0.1 kmol of argon gas at 25°C, 200 kPa and the tank keeps constant volume. To what T should it be heated to have a mole fraction of atomic hydrogen, H, of 10%?

For the reaction $H_2 \Leftrightarrow 2H$, $K = \dfrac{y_H^2}{y_{H_2}} \left(\dfrac{P}{P^o}\right)^{2-1}$

Assume the dissociation shifts right with an amount x then we get

reaction	H_2	$\Leftrightarrow$	2 H	also,	Ar	
initial	0.1		0		0.1	
change	-x		2x		0	
equil.	0.1 - x		2x		0.1	Tot: 0.2 + x

$$y_H = \frac{2x}{0.2 + x} = 0.10 \quad \Rightarrow \quad x = 0.010526$$

We need to find T so K will take on the proper value, since K depends on P we need to evaluate P first.

$$P_1 V = n_1 \bar{R} T_1; \quad P_2 V = n_2 \bar{R} T_2 \quad \Rightarrow \quad P_2 = P_1 \frac{n_2 T_2}{n_1 T_1}$$

where we have $n_1 = 0.2$ and $n_2 = 0.2 + x = 0.210526$

$$K = \frac{y_H^2}{y_{H_2}} \left(\frac{P}{P^o}\right)^{2-1} = \frac{(2x)^2}{(0.1 - x)\, n_2} \frac{200}{100} \frac{n_2 T_2}{0.2 \times 298.15} = 0.0001661\ T_2$$

Now it is trial and error to get T_2 so the above equation is satisfied with K from A.11 at T_2.

3600 K: ln K = -0.611, K = 0.5428, RHS = 0.59796, error = 0.05516

3800 K: ln K = 0.201, K = 1.22262, RHS = 0.63118, error = -0.59144

Linear interpolation between the two to make zero error

$$T = 3600 + 200 \times \frac{0.05516}{0.05516 + 0.59144} = \mathbf{3617\ K}$$

14.59

A local stoichiometric combustion of butene C_4H_8 results in only half the C atoms burns to CO_2 and the other half generates CO. This means the products should contain a mixture of H_2O, CO, CO_2, O_2 and N_2 which after heat transfer are at 1000 K.

a) Write the combustion equation assuming no hydrogen in the products

b) Use the water gas reaction to estimate the amount of hydrogen H_2 present.

Select the amount of air for stoichiometric combustion
Combustion:

$$C_4H_8 + 6(O_2 + 3.76N_2) \Rightarrow 2CO_2 + 2\,CO + 4\,H_2O + 1\,O_2 + 22.56\,N_2$$

Since we have 2 CO we did not use 1 O_2 which is then left in the products.

Water-gas reaction: $H_2 + CO_2 \Leftrightarrow H_2O + CO$

	CO_2	CO	H_2O	H_2	O_2	N_2	
Start	2	2	4	0	1	22.56	
Change	-x	x	x	-x	0	0	
Final	2-x	2 +x	4+x	-x	1	22.56	tot = 31.56

Notice the total number of moles is constant. See Example 14.4 for the equilibrium K

At 1000 K: $\ln K = 0.5(\ln K_1 - \ln K_2) = 0.5[-47.052 - (-46.321)] = -0.3655$

$$K = \exp(-0.3655) = [\, y_{CO}\, y_{H2O} / y_{CO2}\, y_{H2}]\, 1 = \frac{2 + x}{2 - x}\,\frac{4 + x}{- x}$$

Reduce and solve: $(2 - x)(- x) \exp(-0.3655) = (2 + x)(4 + x)$

$$\Rightarrow \quad -(2x - x^2) \exp(-0.3655) = 8 + 6x + x^2$$

$-2 < x < 0$ for all pos. concentrations $\Rightarrow \quad x = -1.136$

n_{H2} = **1.136 mol/mol fuel** or 3.6%

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.60

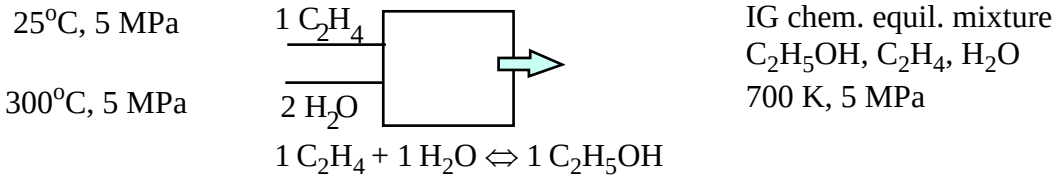
A liquid fuel can be produced from a lighter fuel in a catalytic reactor according to

$$C_2H_4 + H_2O \quad \Leftrightarrow \quad C_2H_5OH$$

Show the equilibrium constant is ln K = –6.691 at 700 K using C_P = 63 kJ/kmol K for ethylene and C_P = 115 kJ/kmol K for ethanol at 500 K.



$$1\,C_2H_4 + 1\,H_2O \Leftrightarrow 1\,C_2H_5OH$$

$$\Delta H^0_{700\ K} = 1(-235\,000 + 115(700-298.2)) - 1(+52\,467 + 63\,(700-298.2))$$
$$- 1(-241\,826 + 14\,190) = -38\,935\ kJ$$

$$\Delta S^0_{700\ K} = 1(282.444 + 115 \ln \frac{700}{298.2}) - 1(219.330 + 63 \ln \frac{700}{298.2}) - 1(218.739)$$
$$= -111.253\ kJ/K$$

$$\Delta G^0_{700\ K} = \Delta H^0 - T\Delta S^0 = -38\,935 - 700(-111.253) = +38\,942\ kJ$$

$$\ln K = \frac{-\Delta G^0}{\bar{R}T} = -\frac{38\,942}{8.31451 \times 700} = \mathbf{-6.691}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.61

A rigid container initially contains 2 kmol of carbon monoxide and 2 kmol of oxygen at 25°C, 100 kPa. The content is then heated to 3000 K at which point an equilibrium mixture of CO_2, CO, and O_2 exists. Disregard other possible species and determine the final pressure, the equilibrium composition and the heat transfer for the process.

Equilibrium process: $2\,CO + 2\,O_2 \Leftrightarrow 2\,CO_2 + O_2$

Species:	CO	O_2	CO_2
Initial	2	2	0
Shift	-2x	-2x+x	2x
Final	2-2x	2-x	2x :

$n_{tot} = 2 - 2x + 2 - x + 2x = 4 - x$

$$y_{CO} = \frac{2-2x}{4-x}; \quad y_{O_2} = \frac{2-x}{4-x}; \quad y_{CO_2} = \frac{2x}{4-x}$$

Energy equation

$$U_2 - U_1 = {}_1Q_2 = H_2 - H_1 - P_2v + P_1v$$

$$= (2 - 2x)\bar{h}_{CO\,2} + (2 - x)\bar{h}_{O_2 2} + 2x\bar{h}_{CO_2} - 2\bar{h}^o_{fCO_2} - 2\bar{h}^o_{fO_2}$$

$$- \bar{R}\,(4 - x)T_2 + 4\bar{R}T_1$$

Notice P_2 is unknown so write it in terms of T_2 and the number of moles. We flipped the reaction relative to the one in A.11 so then $K_{eq} = 1/\,K_{eq\ A11}$

$$K_{eq} = e^{2.217} = \frac{y^2_{CO_2}}{y_{0_2} y^2_{CO}} \left(\frac{P_2}{P_o}\right)^{-1} = \frac{4x^2}{4(1 - x)^2}\,\frac{4 - x}{2 - x}\,\frac{4T_1}{(4 - x)T_2}$$

$$\Rightarrow \quad \left(\frac{x}{1 - x}\right)^2 \frac{1}{2 - x} = \frac{1}{4}\frac{T_2}{T_1} e^{2.217} = 23.092 \quad \Rightarrow \quad x = 0.8382;$$

y_{CO} = **0.102**; y_{O_2} = **0.368**; y_{CO_2} = **0.53**

Constant volume and ideal gas approximation $PV = n\bar{R}T$

$$P_2 = P_1(4 - x)\,T_2\,/4T_1 = 100\,\frac{(4 - 0.8382) \times 3000}{4 \times 298.15} = \textbf{795.4 kPa}$$

$${}_1Q_2 = 0.3236(-110527 + 93504) + 1.1618(98013) + 1.6764(-393522$$
$$+ 152853) - 2(-110527) - 2(Ø) + 8.3145[4(298.15) - 3000(3.1618)]$$
$$= -\textbf{142991 kJ}$$

14.62

Use the information in Problem 14.90 to estimate the enthalpy of reaction, ΔH^o, at 700 K using Van't Hoff equation (see problem 14.56) with finite differences for the derivatives.

$$d \ln K = [\Delta H°/\bar{R}T^2]\, dT \quad \text{or} \quad \text{solve for } \Delta H^o$$

$$\Delta H° = \bar{R}T^2 \frac{d \ln K}{dT} = \bar{R}T^2 \frac{\Delta \ln K}{\Delta T}$$

$$= 8.31451 \times 700^2 \times \frac{-0.3362 - (-4.607)}{800 - 600} = 86\,998 \text{ kJ/kmol}$$

[Remark: compare this to A.9 values + A.5, A.10,

$$\Delta H^o = H_C + 2H_{H_2} - H_{CH_4} = 0.61 \times 12 \times (700\text{-}298) + 2 \times 11730$$

$$- 2.254 \times 16.04 \times (700\text{-}298) - (-74873) = 86\,739 \text{ kJ/kmol }]$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.63

One kilomole of carbon dioxide, CO_2, and 1 kmol of hydrogen, H_2 at room temperature, 200 kPa is heated to 1200 K at 200 kPa. Use the water gas reaction to determine the mole fraction of CO. Neglect dissociations of H_2 and O_2.

$$1\,CO_2 + 1\,H_2 \Leftrightarrow 1\,CO + 1\,H_2O$$

Initial	1	1	0	0	
Shift	-x	-x	+x	+x	
Total	1-x	1-x	x	x;	$n_{tot} = 2$

$y_{H2O} = y_{CO} = x/2$, $y_{H2} = y_{CO2} = (1-x)/2$

The water gas reaction, see Example 14.4

At 1200 K, $\ln K_{III} = 0.5\,(-35.736 - (-36.363)) = +\,0.3135$,

$$K = 1.3682$$

$$\frac{(x/2)(x/2)}{(\frac{1-x}{2})(\frac{1-x}{2})} = K = \frac{x^2}{(1-x)^2} \quad \Rightarrow \quad \frac{x}{1-x} = 1.1697$$

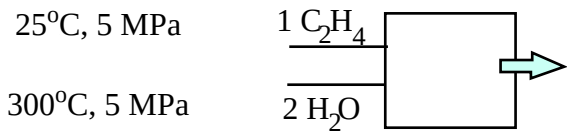
$$x = 1.1697 / 2.1697 = 0.5391$$

$y_{H2O} = y_{CO} = x/2 =$ **0.27**, $y_{H2} = y_{CO2} = (1-x)/2 =$ **0.23**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.64

A step in the production of a synthetic liquid fuel from organic waste material is the following conversion process at 5 MPa: 1 kmol ethylene gas (converted from the waste) at 25°C and 2 kmol steam at 300°C enter a catalytic reactor. An ideal gas mixture of ethanol, ethylene and water in equilibrium, see previous problem, leaves the reactor at 700 K, 5 MPa. Determine the composition of the mixture.



$1\ C_2H_4 + 1\ H_2O \Leftrightarrow 1\ C_2H_5OH$

initial	1	2	0	
change	-x	-x	+x	
equil.	(1-x)	(2-x)	x	total = 3 - x

The reaction rate from the previous problem statement is

$$\ln K = \frac{-\Delta G^0}{\bar{R}T} = -6.691 \quad \Rightarrow \quad K = 0.001\,242 = \frac{y_{C2H5OH}}{y_{C2H4}\, y_{H2O}} \left(\frac{P}{P^0}\right)^{-1}$$

$$\Rightarrow \left(\frac{x}{1-x}\right)\left(\frac{3-x}{2-x}\right) = 0.001242 \times \frac{5.0}{0.1} = 0.0621$$

By trial and error: x = 0.0404 =>

C_2H_5OH: n = 0.0404, y = 0.01371

C_2H_4: n = 0.9596, y = 0.3242, H_2O: n = 1.9596 , y = 0.6621

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.65

A special coal burner uses a stoichiometric mixture of coal and an oxygen - argon mixture (1:1 mole ratio) with the reactants supplied at Po, To. Consider the dissociation of CO_2 into CO and O_2 and no others. Find the equilibrium composition of the products for T = 4800 K. Is the final temperature, including dissociations, higher or lower than 4800 K?

Combustion: $C + O_2 + Ar \Rightarrow CO_2 + Ar$

Reaction:

$2\,CO_2 \Leftrightarrow 2\,CO + O_2$

	CO_2	CO	O_2	Ar	
Start	1	0	0	1	
Change	-2x	2x	x	0	
Final	1-2x	2x	x	1	tot = 2 + x

At 4800 K: $K = \exp(5.8322) = [\, y_{CO}^2\, y_{O2} / y_{CO2}^2]\, 1 = [(\frac{2x}{2+x})^2 \frac{x}{2+x} / (\frac{1-2x}{2+x})^2]$

Reduce and solve: $x^3 = [\, \exp(5.8322)/4 \,]\, (2 + x)\, (1 - 2x)^2$

$\Rightarrow \quad x^3 = 085.277\, (2 + x)\, (1 - 2x)^2 \quad \Rightarrow \quad x = 0.4885$ (close)

$n_{CO} = 0.977,\ n_{O2} = 0.4885,\ n_{CO2} = 0.023,\ n_{Ar} = 1$

Now we can do the energy equation:

$$H_{P\ 4800\ K} = 0.023\,(266\,488 - 393\,522) + 1 \times 20.773\,(4800 - 298) + 0.977\,(161\,285 - 110\,527) + 0.4885 \times 172\,240 = 224\,325\ \text{kJ/kmol}$$

Since $H_{P\ 4800\ K} > 0$ then **T < 4800 K**

We should have had $H_P = 0$, if we match the energy equation to find the T we have to redo the equilibrium equation as K is different. This is a larger trial and error problem to find the actual T and we even neglected other possible reactions.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.66

Acetylene gas at 25°C is burned with 140% theoretical air, which enters the burner at 25°C, 100 kPa, 80% relative humidity. The combustion products form a mixture of CO_2, H_2O, N_2, O_2, and NO in chemical equilibrium at 2200 K, 100 kPa. This mixture is then cooled to 1000 K very rapidly, so that the composition does not change. Determine the mole fraction of NO in the products and the heat transfer for the overall process.

$$C_2H_2 + 3.5\,O_2 + 13.16\,N_2 + \text{water} \rightarrow$$
$$2\,CO_2 + 1\,H_2O + 1\,O_2 + 13.16\,N_2 + \text{water}$$

water: $P_V = 0.8 \times 3.169 = 2.535$ kPa

$$n_V = n_A\, P_V/P_A = (3.5 + 13.16)\, 2.535/97.465 = 0.433$$

So, total H_2O in products is 1.433.

Reaction: $N_2 + O_2 \Leftrightarrow 2\,NO$

change : -x -x +2x

at 2200 K, from A.11: $K = \exp(-6.836) = 0.001\,074$

Equil. products: $n_{CO2} = 2$, $n_{H2O} = 1.433$, $n_{O2} = 1 - x$,

$n_{N2} = 13.16 - x$, $n_{NO} = 0 + 2x$, $n_{TOT} = 17.593$

$$K = \frac{(2x)^2}{(1 - x)(13.16 - x)} = 0.001\,074 \quad \Rightarrow \quad x = 0.0576$$

$$y_{NO} = \frac{2 \times 0.0576}{17.593} = \mathbf{0.006\,55}$$

Final products (same composition) at 1000 K, reactants at 25°C

$$H_R = 1(226\,731 + 0) + 0.433(-241\,826 + 0) = 122\,020 \text{ kJ}$$

$$H_P = 2(-393\,522 + 33\,397) + 1.433(-241\,826 + 26\,000)$$
$$+ 0.9424(0 + 22\,703) + 13.1024(0 + 21\,463)$$
$$+ 0.1152(90\,291 + 22\,229)$$
$$= -713\,954 \text{ kJ}$$

$$Q_{CV} = H_P - H_R = \mathbf{-835\,974\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.67

Coal is burned with stoichiometric air, with the reactants supplied at the reference conditions Po, To. If no dissociations are considered, the adiabatic flame temperature is found to be 2461 K. What is it if the dissociation of CO_2 is included?

Combustion: $C + 1(O_2 + 3.76\ N_2) \Rightarrow CO_2 + 3.76\ N_2$

The dissociation of CO_2 is: $2CO_2 \Leftrightarrow 2\ CO + O_2$

	CO_2	CO	N_2	O_2	
Start	1	0	3.76	0	
Change	-2e	2e		e	
Final	1-2e	2e	3.76	e;	Total = 4.76 + e

Reaction constant: $$K = \frac{y_{CO}^2\, y_{O2}}{y_{CO2}^2}\left(\frac{P}{P_o}\right)^{3-2} = \frac{(2e)^2\, e}{(1 - 2e)^2(4.76 + e)} \qquad (1)$$

Products at equilibrium: $(1\text{-}2e)\ CO_2 + 2e\ CO + 3.76\ N_2 + e\ O_2$

Energy Eq.: $H_R = H_P = H_P^o + \Delta H_P = 0$

$$H_P = (1\text{-}2e)\ (\bar{h}_f^0 + \Delta H)_{CO2} + 2e\ (\bar{h}_f^0 + \Delta H)_{CO} + 3.76\ \Delta H_{N2} + e\ \Delta H_{O2}$$

$$0 = (1\text{-}2e)\ (-393\ 522 + \Delta H_{CO2}) + 2e\ (-110\ 527 + \Delta H_{CO}) + 3.76\ \Delta H_{N2} + e\ \Delta H_{O2} \qquad (2)$$

We need to satisfy equations (1) and (2), both functions of T and e. We know T must be less than 2461 K as the dissociation requires energy and that e is small.

Guess 2400 K: K = exp(-7.715) = 0.000446, Eq.1 => e = 0.07322

$H_P = 0.85356(-393522 + 115779) + 0.14644(-110\ 527 + 71326) + 3.76 \times 70640 + 0.07322 \times 74453 = 28\ 247$ kJ/kmol

This shows that H_P is too high so also then e too high

Guess 2200 K: K = exp(-10.232) = 0.000036, Eq.1 => e = 0.03349

$H_P = 0.93302(-393522 + 103562) + 0.06698(-110\ 527 + 64012) + 3.76 \times 63362 + 0.03349 \times 66770 = -33176.8$ kJ/kmol

Now H_P is too small, so linear interpolation to hit $H_P = 0$

$T = 2200 + 200\ [0 - (-33\ 176.8)]/[28\ 247 - (-33\ 176.8)] = 2308$ K

To confirm try T = 2300 K: K = exp(-8.9735) = 0.0001267, e = 0.0498

$H_P = 0.9004(-393522 + 109670.5) + 0.0996(-110\ 527 + 67669) + 3.76 \times 67001 + 0.03349 \times 70611.5 = -5560$ kJ/kmol

Final linear interpolation: $T = 2300 + 100 \times 5560/(28\ 247 + 5560) =$ **2316 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.68

An important step in the manufacture of chemical fertilizer is the production of ammonia, according to the reaction: $N_2 + 3H_2 \Leftrightarrow 2NH_3$ Show that the equilibrium constant is K = 6.202 at 150°C.

$$1\ N_2 + 3\ H_2 \Leftrightarrow 2\ NH_3 \quad \text{at } 150^oC$$

Assume ideal gas and constant specific heat for ammonia (we could be more accurate if we used Table B.2 realizing properties depend also on P). We must use the reference h, s values from Table A.10

$$\bar{h}^o_{NH3\ 150\ C} = -45\ 720 + 2.13 \times 17.031(150 - 25) = -41\ 186\ \text{kJ/kmol}$$

$$\bar{s}^o_{NH3\ 150\ C} = 192.572 + 2.13 \times 17.031 \ln\frac{423.2}{298.2} = 205.272\ \text{kJ/kmol-K}$$

Use Table A.9 for nitrogen and hydrogen gases

$$\Delta H^o_{150\ C} = 2(-41\ 186) - 1(0+3649) - 3(0 + 3636) = -96\ 929\ \text{kJ/kmol}$$

$$\Delta S^0_{150\ C} = 2(205.272) - 1(201.829) - 3(140.860) = -213.865\ \text{kJ/kmol-K}$$

$$\Delta G^0_{150\ C} = -96\ 929 - 423.2(-213.865) = -6421\ \text{kJ/kmol}$$

$$\ln K = \frac{+6421}{8.31451 \times 423.15} = 1.8248, \quad \mathbf{K = 6.202}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.69

Consider the previous reaction in equilibrium at 150°C, 5 MPa. For an initial composition of 25% nitrogen, 75% hydrogen, on a mole basis, calculate the equilibrium composition

Reaction:	$1\ N_2$	$+\ 3\ H_2$	$\Leftrightarrow\ 2\ NH_3$	at 150°C	progress variable x
Beginning:	1	3	0		
Change:	-x	-3x	2x		
Final:	1-x	3-3x	2x	Total:	$n = 4 - 2x$

The reaction constant is $K = 6.202$ so the reaction constant equation is

$$K = \frac{y_{NH3}^2}{y_{N2} y_{H2}^3}\left(\frac{P}{P^0}\right)^{-2} = \frac{(2x)^2(4 - 2x)^2}{3^3(1 - x)^4}\left(\frac{P}{P^0}\right)^{-2}$$

$$\text{or} \quad \left(\frac{x}{1-x}\right)^2\left(\frac{2-x}{1-x}\right)^2 = \frac{27}{16} \times 6.202 \times \left(\frac{5}{0.1}\right)^2 = 26165$$

$$\text{or} \quad \left(\frac{x}{1-x}\right)\left(\frac{2-x}{1-x}\right) = 161.755$$

$\rightarrow$ Trial & Error: $x = 0.9215$

	n	y

14.70

At high temperature, NO can form from oxygen and nitrogen. Natural gas (methane) is burned with 150% theoretical air at 100 kPa, and the product temperature is 2000 K. Neglect other reactions and find the equilibrium concentration of NO. Does the formation of the NO change the temperature?

Combustion: $CH_4 + 1.5 \times 2(O_2 + 3.76\ N_2) \rightarrow CO_2 + 2H_2O + 1O_2 + 11.28\ N_2$

Reaction: $N_2 + O_2 \Leftrightarrow 2\ NO$, progress x

	N_2	+ O_2	$\Leftrightarrow$ 2 NO	H_2O+CO_2	
initial	11.28	1	0	2+1	
change	-x	-x	+2x	0	
equilibrium	1-x	1-x	2x	3	$n_{TOT} = 5$

$$K = \exp(-7.825) = 0.0003996 = \frac{y_{NO}^2}{y_{N2}\, y_{O2}} \left(\frac{P}{P_o}\right)^{2-2} = \frac{(2x)^2}{(1-x)(1-x)} = \left(\frac{2x}{1-x}\right)^2$$

Solve

$$2x/(1-x) = \sqrt{0.0003996} = 0.01999 \quad => \quad x = 0.009896$$

$$y_{NO} = 2x/5 = \mathbf{0.00396}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.71

Methane at 25°C, 100 kPa, is burned with 200% theoretical oxygen at 400 K, 100 kPa, in an adiabatic steady state process, and the products of combustion exit at 100 kPa. Assume that the only significant dissociation reaction in the products is that of carbon dioxide going to carbon monoxide and oxygen. Determine the equilibrium composition of the products and also their temperature at the combustor exit.

Combustion: $CH_4 + 4O_2 \rightarrow CO_2 + 2H_2O + 2O_2$

Dissociation:

	$2\,CO_2 \Leftrightarrow$	$2\,CO$	$+\ O_2$	$,H_2O$	inert	
initial	1	0	2	2		
change	-2x	+2x	+x	0		
equilibrium	1-2x	2x	2+x	2		$n_{TOT} = 5+x$

Equil. Eq'n: $K = \dfrac{y_{CO}^2 y_{O2}}{y_{CO2}^2}\left(\dfrac{P}{P^0}\right) = \left(\dfrac{x}{0.5 - x}\right)^2\left(\dfrac{2 + x}{5 + x}\right)\left(\dfrac{P}{P^0}\right)$

or $$\left(\frac{x}{0.5 - x}\right)^2\left(\frac{2 + x}{5 + x}\right) = \frac{K}{(P/P^0)} \qquad (1)$$

Energy Eq.: $H_P - H_R = 0$

$$(1-2x)(-393\,522 + \Delta\bar{h}_{CO2}) + 2x(-110\,527 + \Delta\bar{h}_{CO})$$

$$+ 2(-241\,826 + \Delta\bar{h}_{H2O}) + (2+x)\Delta\bar{h}_{O2} - 1(-74\,873) - 4(3027) = 0$$

or $$(1-2x)\Delta\bar{h}_{CO2} + 2x\Delta\bar{h}_{CO} + 2\Delta\bar{h}_{H2O} + (2+x)\Delta\bar{h}_{O2} + 565\,990x - 814\,409 = 0$$

Assume $T_P = 3256$ K. From A.11: $K = 0.6053$

Solving (1) by trial & error, $x = 0.2712$

Substituting x and the $\Delta\bar{h}$ values from A.9 (at 3256 K) into (2)

$$0.4576\times168\,821 + 0.5424\times103\,054 + 2\times140\,914$$

$$+ 2.2712\times108\,278 + 565\,990\times0.2712 - 814\,409 \approx 0 \quad \text{OK}$$

$T_P = 3256$ K & $x = 0.2712$

$n_{CO2} = 0.4576$, $n_{CO} = 0.5424$, $n_{H2O} = 2.0$, $n_{O2} = 2.2712$

$y_{CO2} = 0.0868$, $y_{CO} = 0.1029$, $y_{H2O} = 0.3794$, $y_{O2} = 0.4309$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.72

Calculate the irreversibility for the adiabatic combustion process described in the previous problem.

From solution of Prob. 14.71, it is found that the product mixture consists of $0.4576\,CO_2$, $0.5424\,CO$, $2.0\,H_2O$ & $2.2712\,O_2$ at 3256 K, 100 kPa. The reactants include

$$1\,CH_4 \text{ at } 25\ ^oC,\ 100 \text{ kPa and } 4\,O_2 \text{ at } 400 \text{ K, } 100 \text{ kPa.}$$

Reactants:

$$S_R = 1(186.251) + 4(213.873) = 1041.74 \text{ kJ/K}$$

Products:

	n_i	y_i	$\bar{s}_i^0$	$-\bar{R} \ln \frac{y_i P}{P_0}$	$\bar{S}_i^*$
CO_2	0.4576	0.0868	339.278	+20.322	359.600
CO	0.5424	0.1029	276.660	+18.907	295.567
H_2O	2.0	0.3794	291.099	+8.058	299.157
O_2	2.2712	0.4309	287.749	+7.000	294.749

$$S_P = 0.4576(359.600) + 0.5424(295.567) + 2.0(299.157)$$
$$+ 2.2712(294.749) = 1592.62 \text{ kJ/K}$$

$$I = T_0(S_P - S_R) - Q_{CV} = 298.15(1592.62 - 1041.74) - 0 = \mathbf{164\ 245\ kJ}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.73

Consider the stoichiometric combustion of pure carbon with air in a constant-pressure process at 100 kPa. Find the adiabatic flame temperature (no equilibrium reactions). Then find the temperature the mixture should be heated/cooled to so that the concentrations of CO and CO_2 are the same.

Conbustion: $C + 1(O_2 + 3.76\ N_2) \Rightarrow CO_2 + 3.76\ N_2$

Energy Eq.: $H_R = H_P = H_P^o + \Delta H_P$

$\Delta H_P = H_R - H_P^o = -H_{RP}^o = HV = 393\ 522$ kJ/kmole

$= \Delta H_{CO2} + 3.76\ \Delta H_{N2}$

$\Delta H_{P\ 3000\ K} = 152\ 853 + 3.76 * 92\ 715 = 501\ 461$ too big

$\Delta H_{P\ 2400\ K} = 115\ 779 + 3.76 * 70\ 640 = 381\ 385$ too small

$\Delta H_{P\ 2600\ K} = 128\ 074 + 3.76 * 77\ 963 = 421\ 215$ too big

Interpolate: **T = 2461 K**

Assume now the dissociation of CO_2 as: $2CO_2 \Leftrightarrow 2\ CO + O_2$

	CO_2	CO	N_2	O_2	
Start	1	0	3.76	0	
Change	-2e	2e		e	
Final	1-2e	2e	3.76	e;	Total = 4.76 + e

When the two concentrations are the same then

$$y_{CO2} = \frac{1 - 2e}{4.76 + e} = y_{CO} = \frac{2e}{4.76 + e} \quad \Rightarrow \quad 1 - 2e = 2e \quad \Rightarrow \quad e = ¼$$

Reaction constant

$$K = \frac{y_{CO}^2\, y_{O2}}{y_{CO2}^2}\left(\frac{P}{P_o}\right)^{3-2} = y_{O2} = \frac{0.25}{4.76 + 0.25} = 0.0499 = \exp(-2.9977)$$

Now look in Table A.11: $\ln K_T = -2.9977$ => Interpolate: T = **2900 K**

Check for other reactions possible:

$N_2 \Rightarrow 2N$	$K_T = \exp(-23.5)$	no progress to RHS
$O_2 \Rightarrow 2O$	$K_T = \exp(-5.09)$	minor progress to RHS
$N_2 + O_2 \Rightarrow 2NO$	$K_T = \exp(-4.5)$	minor progress to RHS

To be very accurate we should look at the last two reactions also.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.74

Hydrides are rare earth metals, M, that have the ability to react with hydrogen to form a different substance MH_x with a release of energy. The hydrogen can then be released, the reaction reversed, by heat addition to the MH_x. In this reaction only the hydrogen is a gas so the formula developed for the chemical equilibrium is inappropriate. Show that the proper expression to be used instead of Eq. 14.14 is

$$\ln (P_{H2}/P^o) = \Delta G^o/RT$$

when the reaction is scaled to 1 kmol of H_2.

$$M + \frac{1}{2} x\ H_2 \quad \Leftrightarrow \quad MH_x$$

At equilibrium $G_P = G_R$, assume g of the solid is a function of T only.

$$\bar{g}_{MHx} = \bar{h}^0_{MHx} - T\bar{s}^0_{MHx} = \bar{g}^0_{MHx}\,, \quad \bar{g}_M = \bar{h}^0_M - T\bar{s}^0_M = \bar{g}^0_M$$

$$\bar{g}_{H2} = \bar{h}^0_{H2} - T\bar{s}^0_{H2} + \bar{R}T \ln(P_{H2}/P_o) = \bar{g}^0_{H2} + \bar{R}T \ln(P_{H2}/P_o)$$

$$G_P = G_R: \qquad \bar{g}_{MHx} = \bar{g}_M + \frac{1}{2} x\ \bar{g}_{H2} = \bar{g}^0_M + \frac{1}{2} x[\bar{g}^0_{H2} + \bar{R}T \ln(P_{H2}/P_o)]$$

$$\Delta\bar{G}^0 = \bar{g}^0_{MHx} - \bar{g}^0_M - x\ \bar{g}^0_{H2}/2 = \bar{g}^0_{MHx} - \bar{g}^0_M$$

Scale to 1 mole of hydrogen

$$\Delta\tilde{G}^0 = (\bar{g}^0_{MHx} - \bar{g}^0_M)/(x/2) = \bar{R}T \ln(P_{H2}/P^o)$$

which is the desired result.

14.75

For the process in Problem 14.46 should the dissociation of oxygen also be considered? Verbal answer but supported by numbers.

The dissociation of oxygen

Reaction: $O_2 \leftrightarrow 2\ O$ From A.11: $K_T = \exp(-4.356) = 0.01283$

Equilibrium: $K_T = 0.01283 = \dfrac{y_O^2}{y_{0_2}} \left(\dfrac{P}{P^0}\right) = \dfrac{y_O^2}{y_{0_2}}$

So we need to solve two simultaneous reaction equations. Due to the small equilibrium constant the concentration of O is going to be small, but it will have the effect of requiring a larger heat transfer to reach 3000 K.

From problem 14.46 $y_{O2} = 0.074$ so assume this is nearly the same

$$y_O = \sqrt{y_{O2} K_T} = \sqrt{0.074 \times 0.01283} = 0.03$$

so about half of the oxygen is dissociated and we do need to solve the proper equations.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.76

Which other reactions should be considered in Problem 14.53 and which components will be present in the final mixture?

$2H_2 + O_2 \Leftrightarrow 2H_2O$ Species H_2 O_2 H_2O

Other possible reactions from table A.11

$H_2 \leftrightarrow 2\,H$ $O_2 \leftrightarrow 2\,O$ $2\,H_2O \leftrightarrow H_2 + 2\,OH$

So the final component list most likely has species as:

H_2 O_2 H_2O H O OH

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.77

Redo Problem 14.46 and include the oxygen dissociation.

Reaction 1: $2\,CO_2 \Leftrightarrow 2\,CO + O_2$ Progress variable x

Reaction 2: $O_2 \Leftrightarrow 2\,O$ Progress variable y

Component	CO_2	CO	O_2	O	Ar
initial	2	1	0	0	1
change	-2x	+2x	x-y	+2y	
equil.	2 - 2x	1 + 2x	x-y	2y	1

The total number of moles is: $n_{TOT} = 4 + x + y$

From Table A.11 at 3000 K:

$$K_1 = \exp(-2.217) = 0.108935 = \frac{y_{CO}^2\, y_{O2}}{y_{CO2}^2}\left(\frac{P}{P_o}\right)^{3-2}$$

$$= \frac{(1+2x)^2}{(4+x+y)^2}\,\frac{x-y}{4+x+y}\,\frac{(4+x+y)^2}{(2-2x)^2}\,(1)^1 = \frac{x-y}{4}\,\frac{(1+2x)^2}{4+x+y}\,\frac{1}{(1-x)^2}$$

then

$$0.43574\,(4+x+y)\,(1-x)^2 = (x-y)\,(1+2x)^2 \qquad (1)$$

$$K_2 = \exp(-4.356) = 0.0128296 = \frac{y_O^2}{y_{O2}}\left(\frac{P}{P_o}\right)^{2-1}$$

$$= \frac{(2y)^2}{(4+x+y)^2}\,\frac{4+x+y}{x-y}\,(1)^1 = 4\,\frac{y^2}{4+x+y}\,\frac{1}{x-y}$$

$$0.0032074\,(4+x+y)\,(x-y) = y^2 \qquad (2)$$

The two eq. (1) and (2) must be solved for the two variables (x,y) with the restrictions $x \geq y \geq 0$ and $0 \leq x \leq 1$. Solution is: $x = 0.347805$, $y = 0.06343$

The outlet has: $1.30439\,CO_2 + 1.69561\,CO + 1\,Ar + 0.28438\,O_2 + 0.12686\,O$

Energy equation gives from Table A.9 and A.5 (for argon $C_p\Delta T$) plus the enthalpy of formation as the composition changes from inlet to exit.

$$\dot{Q} = \sum \dot{n}_{ex}\,\bar{h}_{ex} - \sum \dot{n}_{in}\,\bar{h}_{in}$$

$$= 1.30439\,(152853 - 393522) + 1.69561\,(93504 - 110527)$$
$$+ 1\,(39.948 \times 0.52 \times (3000 - 298)) + 0.28438\,(98013)$$
$$+ 0.12686\,(56574 + 249170) - 2\,(-393522) - 1(-110527) - 1\,(0)$$

$$= \mathbf{677\ 568\ kW}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.78

Ethane is burned with 150% theoretical air in a gas turbine combustor. The products exiting consist of a mixture of CO_2, H_2O, O_2, N_2, and NO in chemical equilibrium at 1800 K, 1 MPa. Determine the mole fraction of NO in the products. Is it reasonable to ignore CO in the products?

Combustion:

$$C_2H_6 + 5.25\,O_2 + 19.74\,N_2 \rightarrow 2\,CO_2 + 3\,H_2O + 1.75\,O_2 + 19.74\,N_2$$

Products at 1800 K, 1 MPa

Equilibrium mixture: CO_2, H_2O, O_2, N_2, NO

	N_2	+ O_2	$\Leftrightarrow$	2 NO
initial	19.74	1.75		0
change	-x	-x		+2x
equil.	19.74-x	1.75-x		2x

Equil. comp. $n_{CO2} = 2$, $n_{O2} = 1.75\text{-}x$, $n_{NO} = 2x$, $n_{H2O} = 3$, $n_{N2} = 19.74\text{-}x$

$$K = 1.192\times10^{-4} = \frac{y_{NO}^2}{y_{N2}y_{O2}}\left(\frac{P}{P^0}\right)^0 = \frac{4x^2}{(19.74\text{-}x)(1.75\text{-}x)}$$

Solving, x = 0.031 75

$$y_{NO} = \frac{2\times0.031\,75}{26.49} = \mathbf{0.0024}$$

b)

	$2\,CO_2$	$\Leftrightarrow$	$2\,CO$	+	O_2
initial	2		0		0
change	-2a		+2a		+2x
equil.	2-2a		2a		2x

$$K = 4.194\times10^{-8} = \frac{y_{CO}^2 y_{O2}}{y_{CO2}^2}\left(\frac{P}{P^0}\right)^1 = \left(\frac{2a}{2\text{-}2a}\right)^2\left(\frac{1.75\text{-}x+a}{26.49+a}\right)\times\frac{1}{0.1}$$

This equation should be solved simultaneously with the equation solved in part a) (modified to include the unknown a). Since x was found to be small and also a will be very small, the two are practically independent. Therefore, use the value x = 0.031 75 in the equation above, and solve for a.

$$\left(\frac{a}{1\text{-}a}\right)^2\left(\frac{1.75\text{-}0.031\,75+a}{26.49+a}\right) = \left(\frac{0.1}{1.0}\right)\times 4.194\times10^{-8}$$

Solving, a = 0.000 254 or $y_{CO} = 1.92\times10^{-5}$ negligible for most applications.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.79

A mixture of 1 kmol water and 1 kmol oxygen at 400 K is heated to 3000 K, 200 kPa, in a steady flow process. Determine the equilibrium composition at the outlet of the heat exchanger, assuming that the mixture consists of H_2O, H_2, O_2, and OH.

Reactions and equilibrium eq'ns the same as in example 14.7 (but different initial composition).

At equil.: $n_{H2O} = 1 - 2a - 2b$, $n_{H2} = 2a + b$, $n_{O2} = 1 + a$

$n_{OH} = 2b$, $n_{TOT} = 2 + a + b$

Since T = 3000 K is the same, the two equilibrium constants are the same:

From Table A.11: $K_1 = 0.002\,062$, $K_2 = 0.002\,893$

The two equilibrium equations are

$$K_1 = \left(\frac{2a + b}{1 - 2a - 2b}\right)^2 \frac{1 + a}{2 + a + b}\left(\frac{P}{P^0}\right); \quad K_2 = \frac{2a + b}{2 + a + b}\left(\frac{2b}{1 - 2a - 2b}\right)^2\left(\frac{P}{P^0}\right)$$

which must be solved simultaneously for a & b. If solving manually, it simplifies the solution to divide the first by the second, which leaves a quadratic equation in a & b - can solve for one in terms of the other using the quadratic formula (with the root that gives all positive moles). This reduces the problem to solving one equation in one unknown, by trial & error.

Solving => b = 0.116, a = -0.038 =>

$n_{H2O} = 0.844$, $n_{H2} = 0.0398$, $n_{O2} = 0.962$, $n_{OH} = 0.232$, $n_{TOT} = 2.0778$

$y_{H2O} = 0.4062$, $y_{H2} = 0.0191$, $y_{O2} = 0.4630$, $y_{OH} = 0.1117$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.80

Assume dry air (79% N_2 and 21% O_2) is heated to 2000 K in a steady flow process at 200 kPa and only the reactions listed in Table A.11 are possible (and their linear combinations). Find the final composition (anything smaller than 1 ppm, parts per million, is neglected) and the heat transfer needed for 1 kmol of air in.

We could have: N_2, N, O_2, O, NO, NO_2

The possible reactions are:

$$N_2 \Leftrightarrow 2\,N \qquad K(T) = \exp(-41.655) \approx 0$$

$$O_2 \Leftrightarrow 2\,O \qquad K(T) = \exp(-14.619) \approx \text{small}$$

$$N_2 + O_2 \Leftrightarrow 2\,NO \qquad K(T) = \exp(-7.825)$$

$$N_2 + 2\,O_2 \Leftrightarrow 2\,NO_2 \qquad K(T) = \exp(-19.136) \approx \text{small}$$

So from this we have only NO extra.

	N_2	+	O_2	⇔	2 NO
initial	0.79		0.21		0
change	-x		-x		+2x
equil.	0.79 - x		0.21 - x		2x

$$K = \exp(-7.825) = 0.0004 = \frac{y_{NO}^2}{y_{N2}y_{O2}}\left(\frac{P}{P^0}\right)^0 = \frac{4x^2}{(0.79 - x)(0.21 - x)}$$

Solving, x = 0.004

$$y_{N2} = 0.786, \quad y_{O2} = 0.206, \quad y_{NO} = 0.008$$

$$Q = H_{ex} - H_{in} = 0.786\,\Delta\bar{h}_{N2} + 0.206\,\Delta\bar{h}_{O2} + 0.008\,\bar{h}_{NO}$$

$$= 0.786\,(56137) + 0.206\,(59176) + 0.008\,(57859 + 90291)$$

$$= \mathbf{57\,499\ kJ/kmol}$$

If we had solved also for the oxygen O and NO_2 formation we would get approximately (neglect the effect on total moles)

$$(y_O^2 / y_{O2})\,(P/P_o) = \exp(-14.619) \quad \Rightarrow \quad y_O \approx 0.0002$$

$$(y_{NO2}^2 / y_{N2}y_{O2}^2)\,(P/P_o)^{-1} = \exp(-19.136) \quad \Rightarrow \quad y_{NO2} \approx 0.000018$$

and the O energy addition would be: 0.0002(35713 + 249170) = 57 kJ/kmol very insignificant.

14.81

One kilomole of water vapor at 100 kPa, 400 K, is heated to 3000 K in a constant pressure steady flow process. Determine the final composition, assuming that H_2O, H_2, H, O_2, and OH are present at equilibrium.

Reactions:

1) $2\,H_2O \Leftrightarrow 2\,H_2 + O_2$ 2) $2\,H_2O \Leftrightarrow H_2 + 2\,OH$

change -2a +2a +a change -2b +b +2b

3) $H_2 \Leftrightarrow 2\,H$

change -c +2c

At equilibrium (3000 K, 100 kPa)

n_{H2O} = 1-2a-2b n_{O2} = a n_H = 2c

n_{H2} = 2a+b-c n_{OH} = 2b n_{TOT} = 1+a+b+c

$$\frac{K_1}{(P/P^0)} = \frac{2.062\times10^{-3}}{1} = \left(\frac{2a+b-c}{1-2a-2b}\right)^2 \left(\frac{a}{1+a+b+c}\right)$$

$$\frac{K_2}{(P/P^0)} = \frac{2.893\times10^{-3}}{1} = \left(\frac{2a+b-c}{1+a+b+c}\right)\left(\frac{2b}{1-2a-2b}\right)^2$$

$$\frac{K_3}{(P/P^0)} = \frac{2.496\times10^{-2}}{1} = \frac{(2c)^2}{(2a+b-c)(1+a+b+c)}$$

These three equations must be solved simultaneously for a, b & c:

a = 0.0622, b = 0.0570, c = 0.0327

and

n_{H2O} = 0.7616	y_{H2O} = 0.6611
n_{H2} = 0.1487	y_{H2} = 0.1291
n_{O2} = 0.0622	y_{O2} = 0.0540
n_{OH} = 0.1140	y_{OH} = 0.0990
n_H = 0.0654	y_H = 0.0568

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.82

Water from the combustion of hydrogen and pure oxygen is at 3800 K and 50 kPa. Assume we only have H_2O, O_2, OH and H_2 as gases with the two simple water dissociation reactions active find the equilibrium composition.

This problem is very similar to Example 14.7 in the text. The only difference is that we have T = 3800 K and P = 50 kPa. From table A.11 we have

$$\ln K_1 = -1.906 ; \quad K_1 = 0.14867; \qquad \ln K_2 = -0.984 ; \qquad K_2 = 0.3738$$

$$K_1 = \left(\frac{2a + b}{1 - 2a - 2b}\right)^2 \frac{a}{1 + a + b}\left(\frac{P}{P^0}\right); \qquad K_2 = \frac{2a + b}{1 + a + b}\left(\frac{2b}{1 - 2a - 2b}\right)^2\left(\frac{P}{P^0}\right)$$

So we have two equations as

$$\left(\frac{2a + b}{1 - 2a - 2b}\right)^2 \frac{a}{1 + a + b} = K_1 / \left(\frac{P}{P^0}\right) = 0.29734 \qquad (1)$$

$$\frac{2a + b}{1 + a + b}\left(\frac{2b}{1 - 2a - 2b}\right)^2 = K_2 / \left(\frac{P}{P^0}\right) = 0.7476 \qquad (2)$$

Divide the second equation by the first to give

$$\frac{4b^2}{(2a + b)\, a} = \frac{0.7476}{0.29734} = 2.5143$$

or

$$2a^2 + ba - 1.5909\, b^2 = 0$$

$$a = -(b/4) \pm (1/4)\sqrt{b^2 - 4 \times 2 \times (-1.5909\, b^2)} = 0.676256\, b$$

Now we can do trial and error on equation 1 for only one variable, say b:

$$a = 0.14228, \quad b = 0.2104$$

$$n_{H2O} = 1 - 2a - 2b = 0.29464, \qquad n_{H2} = 2a + b = 0.49496,$$

$$n_{O2} = a = 0.14228, \qquad n_{OH} = 2b = 0.4208$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.83

Methane is burned with theoretical oxygen in a steady flow process, and the products exit the combustion chamber at 3200 K, 700 kPa. Calculate the equilibrium composition at this state, assuming that only CO_2, CO, H_2O, H_2, O_2, and OH are present.

Combustion: $CH_4 + 2\,O_2 \rightarrow CO_2 + 2\,H_2O$

Dissociation reactions:

1) $2\,H_2O \Leftrightarrow 2\,H_2 + O_2$ change -2a +2a +a

2) $2\,H_2O \Leftrightarrow H_2 + 2\,OH$ change -2b +b +2b

3) $2\,CO_2 \Leftrightarrow 2\,CO + O_2$ change -2c +2c +c

At equilibrium:

n_{H2O} = 2-2a-2b n_{O2} = a+c n_{CO2} = 1-2c

n_{H2} = 2a+b n_{OH} = 2b n_{CO} = 2c

n_{TOT} = 3+a+b+c

Products at 3200 K, 700 kPa, from A.11

$$K_1 = \exp(-4.916) = 0.007\,328 = \left(\frac{2a+b}{2-2a-2b}\right)^2 \left(\frac{a+c}{3+a+b+c}\right) \left(\frac{700}{100}\right)$$

$$K_2 = \exp(-4.401) = 0.012\,265 = \left(\frac{2b}{2-2a-2b}\right)^2 \left(\frac{2a+b}{3+a+b+c}\right) \left(\frac{700}{100}\right)$$

$$K_3 = \exp(-0.853) = 0.426\,135 = \left(\frac{2c}{1-2c}\right)^2 \left(\frac{a+c}{3+a+b+c}\right) \left(\frac{700}{100}\right)$$

These 3 equations must be solved simultaneously for a, b, & c. If solving by hand divide the first equation by the second, and solve for c = fct(a,b). This reduces the solution to 2 equations in 2 unknowns. Solving,

a = 0.024, b = 0.1455, c = 0.236

Substance:	H_2O	H_2	O_2	OH	CO_2	CO
n	1.661	0.1935	0.260	0.291	0.528	0.472
y	0.4877	0.0568	0.0764	0.0855	0.1550	0.1386

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.84

Butane is burned with 200% theoretical air, and the products of combustion, an equilibrium mixture containing only CO_2, H_2O, O_2, N_2, NO, and NO_2, exit from the combustion chamber at 1400 K, 2 MPa. Determine the equilibrium composition at this state.

Combustion:

$$C_4H_{10} + 13\,O_2 + 48.9\,N_2 \rightarrow 4\,CO_2 + 5\,H_2O + 6.5\,O_2 + 48.9\,N_2$$

Dissociation:

1) $N_2 + O_2 \Leftrightarrow 2\,NO$ 2) $N_2 + 2O_2 \Leftrightarrow 2\,NO_2$

change -a -a +2a change -b -2b +2b

At equilibrium:

$n_{H2O} = 5$ $n_{N2} = 48.9\text{-}a\text{-}b$ $n_{NO} = 2a$

$n_{CO2} = 4$ $n_{O2} = 6.5\text{-}a\text{-}2b$ $n_{NO2} = 2b$

$n_{TOT} = 64.4\text{-}b$

At 1400 K, from A.11: $K_1 = 3.761\times10^{-6}$, $K_2 = 9.026\times10^{-10}$

$$K_1 = \frac{(2a)^2}{(48.9\text{-}a\text{-}b)(6.5\text{-}a\text{-}2b)}\ ; \qquad K_2 = \frac{(2b)^2(64.4\text{-}b)}{(6.5\text{-}a\text{-}2b)^2(48.9\text{-}a\text{-}b)}\left(\frac{P}{P^0}\right)^{-1}$$

As K_1 and K_2 are both very small, with $K_2 << K_1$, the unknowns a & b will both be very small, with b << a. From the equilibrium eq.s, for a first trial

$$a \sim \frac{1}{2}\sqrt{K_1\times48.9\times6.5} \sim 0.0173\ ; \quad b \sim \frac{1}{2}\times6.5\sqrt{K_2\times\frac{2}{0.1}\times\frac{48.9}{64.4}} \sim 0.000\ 38$$

Then by trial & error,

$$\frac{a^2}{(48.9\text{-}a\text{-}b)(6.5\text{-}a\text{-}2b)} = \frac{3.761\times10^{-6}}{4} = 0.940\ 25\times10^{-6}$$

$$\frac{b^2(64.4\text{-}b)}{(6.5\text{-}a\text{-}2b)^2(48.9\text{-}a\text{-}b)} = \frac{9.026\times10^{-10}\times(\frac{2}{0.1})}{4} = 45.13\times10^{-10}$$

Solving, a = 0.017 27, b = 0.000 379

$n_{CO2} = 4$, $n_{H2O} = 5$, $n_{N2} = 48.882$, $n_{O2} = 6.482$,

$y_{CO2} = 0.062\ 11$, $y_{H2O} = 0.077\ 64$, $y_{N2} = 0.759\ 04$, $y_{O2} = 0.100\ 65$

$n_{NO} = 0.034\ 54$, $n_{NO2} = 0.000\ 76$

$y_{NO} = 0.000\ 55$, $y_{NO2} = 0.000\ 01$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.85

One kilomole of air (assumed to be 78% nitrogen, 21% oxygen, and 1% argon) at room temperature is heated to 4000 K, 200 kPa. Find the equilibrium composition at this state, assuming that only N_2, O_2, NO, O, and Ar are present.

1 kmol air (0.78 N_2, 0.21 O_2, 0.01 Ar) heated to

4000 K, 200 kPa.

Equil.:

1) $N_2 + O_2 \Leftrightarrow 2\,NO$

change -a -a +2a

2) $O_2 \Leftrightarrow 2\,O$

change -b +2b

$n_{N2} = 0.78-a$

$n_{O2} = 0.21-a-b$

$n_{Ar} = 0.01$

$n_O = 2b$

$n_{NO} = 2a$

$n_{tot} = 1+b$

$$K_1 = 0.0895 = \frac{4a^2}{(0.78-a)(0.21-a-b)} \left(\frac{200}{100}\right)^0$$

$$K_2 = 2.221 = \frac{4b^2}{(1+b)(0.21-a-b)} \left(\frac{200}{100}\right)$$

Divide 1st eq'n by 2nd and solve for a as function(b), using

$$X = \frac{K_1}{K_2}\left(\frac{P}{P^0}\right) = 0.0806$$

Get

$$a = \frac{Xb^2}{2(1+b)}\left[-1+\sqrt{1+\frac{4\times 0.78(1+b)}{Xb^2}}\right] \qquad (1)$$

Also

$$\frac{b^2}{(1+b)(0.21-a-b)} = \frac{K_2}{4(P/P^0)} = 0.277\,63 \qquad (2)$$

Assume b = 0.1280 From (1), get a = 0.0296

Then, check a & b in (2) $\Rightarrow$ OK

Therefore,

$n_{N2} = 0.7504$ $n_O = 0.2560$ $y_{N2} = 0.6652$ $y_O = 0.2269$

$n_{O2} = 0.0524$ $n_{NO} = 0.0592$ $y_{O2} = 0.0465$ $y_{NO} = 0.0525$

$n_{Ar} = 0.01$ $y_{Ar} = 0.0089$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.86

Acetylene gas and x times theoretical air ($x > 1$) at room temperature and 500 kPa are burned at constant pressure in an adiabatic steady flow process. The flame temperature is 2600 K, and the combustion products are assumed to consist of N_2, O_2, CO_2, H_2O, CO, and NO. Determine the value of x.

Combustion:

$$C_2H_2 + 2.5x\, O_2 + 9.4x\, N_2 \rightarrow 2\, CO_2 + H_2O + 2.5(x\text{-}1)O_2 + 9.4x\, N_2$$

Eq. products 2600 K, 500 kPa: N_2, O_2, CO_2, H_2O, CO & NO

2 Reactions: 1) $2\, CO_2 \Leftrightarrow 2\, CO + O_2$ 2) $N_2 + O_2 \Leftrightarrow 2\, NO$

change -2a +2a +a change -b -b +2b

Equil. Comp.: $n_{N2} = 9.4x\text{-}b$, $n_{H2O} = 1$, $n_{CO} = 2a$, $n_{NO} = 2b$

$n_{O2} = 2.5x - 2.5 + a - b$, $n_{CO2} = 2 - 2a$, $n_{TOT} = 11.9x + 0.5 + a$

At 2600 K, from A.11: $K_1 = 3.721 \times 10^{-3}$, $K_2 = 4.913 \times 10^{-3}$

EQ1: $$\frac{K_1}{(P/P^o)} = \frac{3.721\times10^{-3}}{5} = \left(\frac{a}{1 - a}\right)^2 \left(\frac{2.5x - 2.5 + a - b}{11.9x + 0.5 + a}\right)$$

EQ2: $$K_2 = 4.913\times10^{-3} = \frac{(2b)^2}{(9.4 - b)(2.5x - 2.5 + a - b)}$$

Also, from the energy Eq.: $H_P - H_R = 0$ where

$H_R = 1(+226\ 731) + 0 + 0 = +226\ 731$ kJ

$H_P = (9.4x - b)(0 + 77\ 963) + (2.5x - 2.5 + a - b)(0 + 82\ 225)$

$+ (2 - 2a)(-393\ 522 + 128\ 074) + 1(-241\ 826 + 104\ 520)$

$+ 2a(-110\ 527 + 78\ 679) + 2b(90\ 291 + 80\ 034)$

Substituting H_R and H_P into the energy equation,

EQ3: $988\ 415x + 549\ 425a + 180\ 462b - 1\ 100\ 496 = 0$

which results in 3 equations in the 3 unknowns x, a, b. Assume x = 1.07 then

EQ1: $$7.442 \times 10^{-2} = \left(\frac{a}{1\text{-}a}\right)^2 \left(\frac{0.175 + a - b}{13.233 + a}\right)$$

EQ2: $$1.2283 \times 10^{-3} = \frac{b^2}{(10.058 - b)(0.175 + a + b)}$$

Solving, a = 0.1595, b = 0.0585 Then checking in EQ3,

$988\ 415\times1.07 + 549\ 425\times0.1595 + 180\ 462\times0.0585 - 1\ 100\ 496 \approx 0$

Therefore, x = **1.07**

14.87

One approach to using hydrocarbon fuels in a fuel cell is to "reform" the hydrocarbon to obtain hydrogen, which is then fed to the fuel cell. As a part of the analysis of such a procedure, consider the reforming reaction $CH_4 + H_2O \Leftrightarrow 3H_2 + CO$. Determine the equilibrium constant for this reaction at a temperature of 800 K.

$$CH_4 + H_2O \Leftrightarrow 3H_2 + CO$$

The equilibrium constant from Eq.14.15 depends on ΔG^0 and T.

For CH_4, use C_{P0} at average temperature 550 K $\approx \frac{1}{2}(298 + 800)$ K.

Table A.6, $\bar{C}_{P0} = 49.316$ kJ/kmol K

$$\bar{h}^0_{800\ K} = \bar{h}^0_f + \bar{C}_{P0}\Delta T = -74\,873 + 49.316\,(800 - 298.2)$$

$$= -50\,126 \text{ kJ/kmol}$$

$$\bar{s}^0_{800\ K} = 186.251 + 49.316 \ln \frac{800}{298.2} = 234.918 \text{ kJ/kmol K}$$

The rest of the properties are from Table A.9 at 800 K.

$$\Delta H^0_{800\ K} = 3(0 + 14\,681) + 1(-110\,527 + 15\,174) - 1(-50\,126)$$

$$- 1(-241\,826 + 18\,002) \quad = +222\,640 \text{ kJ/kmol}$$

$$\Delta S^0_{800\ K} = 3(159.554) + 1(227.277) - 1(234.918) - 1(223.826)$$

$$= +247.195 \text{ kJ/kmol K}$$

$$\Delta G^0 = \Delta H^0 - T\Delta S^0 = 222\,640 - 800(247.195) = +24\,884 \text{ kJ/kmol}$$

$$\ln K = -\frac{\Delta G^0}{\bar{R}T} = \frac{-24\,884}{8.3145 \times 800} = -3.7411 \quad \Rightarrow \quad K = \mathbf{0.0237}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.88

A coal gasifier produces a mixture of 1 CO and $2H_2$ that is fed to a catalytic converter to produce methane. The reaction is $CO + 3H_2 \Leftrightarrow CH_4 + H_2O$. The equilibrium constant at 600 K is $K = 1.83 \times 10^6$. What is the composition of the exit flow assuming a pressure of 600 kPa?

The reaction equation is:

	CO	+	$3\,H_2$	$\Leftrightarrow$	CH_4	+	H_2O	
initial	1		2		0		0	
change	–x		–3x		+x		+x	
equil.	1 – x		2 – 3x		x		x	$n_{TOTAL} = 3 - 2x$

$$K = \frac{y_{CH_4}\, y_{H_2O}}{y_{H_2}^{3}\, y_{CO}} \left(\frac{P}{P^o}\right)^{1+1-1-3} = \frac{x^2\,(3 - 2x)^2}{(1-x)(2 - 3x)^3} \left(\frac{P}{P^o}\right)^{-2}$$

$$1.83 \times 10^6 \times \left(\frac{600}{100}\right)^2 = 6.588 \times 10^7 = \frac{x^2\,(3 - 2x)^2}{(1-x)(2 - 3x)^3}$$

Trial and error to solve for x.

x = 0.6654 LHS = 6.719×10^7

x = 0.66538 LHS = 6.41×10^7

x = 0.66539 LHS = 6.562×10^7 close enough

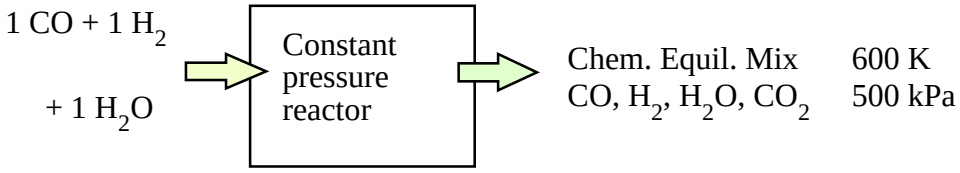
$n_{CH4} = 0.66539$, $n_{H2O} = 0.66539$, $n_{CO} = 0.66539$, $n_{H2} = 0.00383$

so we used up nearly all the hydrogen gas.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.89

Gasification of char (primarily carbon) with steam following coal pyrolysis yields a gas mixture of 1 kmol CO and 1 kmol H_2. We wish to upgrade the hydrogen content of this syngas fuel mixture, so it is fed to an appropriate catalytic reactor along with 1 kmol of H_2O. Exiting the reactor is a chemical equilibrium gas mixture of CO, H_2, H_2O, and CO_2 at 600 K, 500 kPa. Determine the equilibrium composition. Note: see Example 14.4.



(1) $1\,CO + 1\,H_2O \Leftrightarrow 1\,CO_2 + 1\,H_2$ (Water gas reaction)

$-x \quad -x \quad +x \quad +x$

(2) $2\,H_2O \Leftrightarrow 2\,H_2 + 1\,O_2$ (3) $2\,CO_2 \Leftrightarrow 2\,CO + 1\,O_2$

Reaction $(1) = \frac{1}{2}(2) - \frac{1}{2}(3)$

From Table A.11 at 600 K

$$\ln K_1 = \frac{1}{2}\left[-85.79 - (-92.49)\right] = +3.35, \qquad K_1 = 28.503$$

Equilibrium:

$n_{CO} = 1-x, \quad n_{H2O} = 1-x, \quad n_{CO2} = 0 + x, \quad n_{H2} = 1 + x$

$\sum n = 3$, notice the reaction is pressure insensitive.

$$K = \frac{y_{CO2}y_{H2}}{y_{CO}y_{H2O}}\left(\frac{P}{P^0}\right)^0 = \frac{y_{CO2}y_{H2}}{y_{CO}y_{H2O}} = \frac{x(1+x)}{(1-x)^2} = 28.503$$

Solve for x: $x = 0.7794$

	n	y	%
CO	0.2206	0.0735	7.35
H_2O	0.2206	0.0735	7.35
CO_2	0.7794	0.2598	26.0
H_2	1.7794	0.5932	59.3

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.90

The equilibrium reaction as: $CH_4 \Leftrightarrow C + 2H_2$. has ln K = -0.3362 at 800 K and ln$K$ = -4.607 at 600 K. By noting the relation of K to temperature show how you would interpolate ln K in (1/T) to find K at 700 K and compare that to a linear interpolation.

A.11: $\ln K = -0.3362$ at 800K $\qquad$ $\ln K = -4.607$ at 600K

$$\ln K_{700} = \ln K_{800} + \frac{\frac{1}{700} - \frac{1}{800}}{\frac{1}{600} - \frac{1}{800}} \times (-4.607 + 0.3362)$$

$$= -0.3362 + \frac{\frac{800}{700} - 1}{\frac{800}{600} - 1} \times (-4.2708) \quad = \mathbf{-2.1665}$$

Linear interpolation:

$$\ln K_{700} = \ln K_{600} + \frac{700 - 600}{800 - 600} (\ln K_{800} - \ln K_{600})$$

$$= -4.607 + \frac{1}{2}(-0.3362 + 4.607) = -\mathbf{2.4716}$$

Comment: Look at the van't Hoff equation in Problem 14.56 and integrate it with temperature assuming ΔH^0 is constant. That gives $\ln K = C - \Delta H^0/T$.

14.91

One approach to using hydrocarbon fuels in a fuel cell is to "reform" the hydrocarbon to obtain hydrogen, which is then fed to the fuel cell. As a part of the analysis of such a procedure, consider the reaction $CH_4 + H_2O \Leftrightarrow CO + 3H_2$. One kilomole each of methane and water are fed to a catalytic reformer. A mixture of CH_4, H_2O, H_2, and CO exits in chemical equilibrium at 800 K, 100 kPa; determine the equilibrium composition of this mixture using an equilibrium constant of K = 0.0237.

The reaction equation is:

	CH_4	+	H_2O	$\Leftrightarrow$	$3\,H_2$	+	CO
initial	1		1		0		0
change	-x		-x		+3x		+x
equil.	(1-x)		(1-x)		3x		x

$$n_{TOTAL} = 1 - x + 1 - x + 3x + x = 2 + 2x$$

$$K = \frac{y_{H2}^3 y_{CO}}{y_{CH4} y_{H2O}} \left(\frac{P}{P^0}\right)^2 = \frac{(3x)^3 x}{(1 - x)(1 - x)(2 + 2x)^2} \left(\frac{100}{100}\right)^2$$

$$\text{or} \quad \left(\frac{x}{1 - x}\right)^2 \left(\frac{x}{1 + x}\right)^2 = \frac{4 \times 0.0237}{27 \times 1} = 0.003\,51$$

$$\text{or} \quad \frac{x^2}{1 - x^2} = \sqrt{0.003\,51} = 0.059\,25 \quad \text{Solving,} \quad x = 0.2365$$

$$\left.\begin{aligned} n_{CH4} &= 0.7635 \\ n_{H2O} &= 0.7635 \\ n_{H2} &= 0.7095 \\ n_{CO} &= 0.2365 \\ n_{TOT} &= 2.473 \end{aligned}\right\} \left\{\begin{aligned} y_{CH4} &= 0.3087 \\ y_{H2O} &= 0.3087 \\ y_{H2} &= 0.2870 \\ y_{CO} &= 0.0956 \end{aligned}\right.$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.92

Consider a gasifier that receives 4 kmol of carbon-monoxide, 3 kmol hydrogen and 3.76 kmol nitrogen and brings the mixture to equilibrium at 900 K, 1 MPa with the following reaction:

$$2\,CO + 2\,H_2 \Leftrightarrow CH_4 + CO_2$$

which is the sum of Eq.14.32 and 14.33. If the equilibrium constant is K = 2.679 find the exit composition.

The reaction takes place with the nitrogen as a dilutant.

reaction	$2\,CO$	+	$2\,H_2$	$\Leftrightarrow$	CH_4	+	CO_2	also N_2
initial	4		3		0		0	3.76
change	-2x		-2x		+x		+x	0
equil.	(4-2x)		(3-2x)		x		x	3.76

$$n_{TOT} = 10.76 - 2x$$

$$K = \frac{y_{CH4}\, y_{CO2}}{y_{CO}^2\, y_{H2}^2}\left(\frac{P}{P^0}\right)^{-2} = \frac{x \times x \times (10.76 - 2x)^2}{(4 - 2x)^2(3 - 2x)^2}\left(\frac{P}{P^0}\right)^{-2}$$

or take the square-root to get

$$\frac{x(10.76 - 2x)}{(4 - 2x)(3 - 2x)} = \frac{P}{P^0}\sqrt{K} = \frac{1}{0.1}\sqrt{2.679} = 16.368$$

By trial & error or solve the quadratic eq. in x, x = 1.2781

$$n_{CO} = 1.444, \quad n_{H2} = 0.444, \quad n_{CH4} = n_{CO2} = 1.278, \quad n_{N2} = 3.76$$

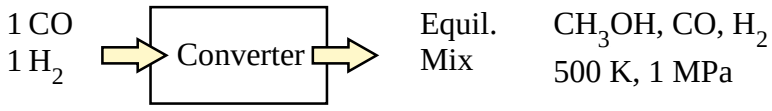
$$y_{CO} = 0.176, \quad y_{H2} = 0.054, \quad y_{CH4} = y_{CO2} = 0.156, \quad y_{N2} = 0.458$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.93

Consider the production of a synthetic fuel (methanol) from coal. A gas mixture of 50% CO and 50% H_2 leaves a coal gasifier at 500 K, 1 MPa, and enters a catalytic converter. A gas mixture of methanol, CO and H_2 in chemical equilibrium with the reaction: $CO + 2H_2 \Leftrightarrow CH_3OH$ leaves the converter at the same temperature and pressure, where it is known that ln K = -5.119.

a. Calculate the equilibrium composition of the mixture leaving the converter.
b. Would it be more desirable to operate the converter at ambient pressure?



Reaction:	CO +	2 H_2 ⇔	CH_3OH
initial	1	1	0
change	-x	-2x	+x
equil.	(1-x)	(1-2x)	x

a) $$K = \frac{y_{CH3OH}}{y_{CO}y_{H2}^2}\left(\frac{P}{P^0}\right)^{-2} = \left(\frac{x}{1\text{-}x}\right)\left(\frac{2\text{-}2x}{1\text{-}2x}\right)^2\left(\frac{P}{P^0}\right)^{-2} \quad => \quad \frac{x(1\text{-}x)}{(1\text{-}2x)^2} = \frac{K}{4}\left(\frac{P}{P^0}\right)^2$$

ln K = -5.119, K = 0.005 98

$$\frac{x(1\text{-}x)}{(1\text{-}2x)^2} = \frac{0.005\ 98}{4}\left(\frac{1}{0.1}\right)^2 = 0.1495 \quad => \quad x = 0.1045$$

n_{CH3OH} = x = 0.1045, n_{CO} = 1-x = 0.8955, n_{H2} = 1 - 2x = 0.791

y_{CH3OH} = 0.0583, y_{CO} = 0.5000, y_{H2} = **0.4417**

b) For P = 0.1 MPa

$$\frac{x(1\text{-}x)}{(1\text{-}2x)^2} = \frac{0.005\ 98}{4}\left(\frac{0.1}{0.1}\right)^2 = 0.001\ 495$$

x is much smaller (~ 0.0015) **not good**

Ionization

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.94

At 10 000 K the ionization reaction for Ar is: $Ar \Leftrightarrow Ar^+ + e^-$ with equilibrium constant of $K = 4.2 \times 10^{-4}$. What should the pressure be for a mole concentration of argon ions (Ar^+) of 10%?

From the reaction (ionization) we recognize that the concentration of electrons must equal that of argon ions so

$$y_{Ar^+} = y_{e^-} = 0.1 \quad \text{and} \quad y_{Ar} = 1 - y_{Ar^+} - y_{e^-} = 0.8$$

Now

$$K = 4.2 \times 10^{-4} = \frac{y_{Ar^+}\, y_{e^-}}{y_{Ar}} \left(\frac{P}{P^o}\right)^{1+1-1} = \frac{0.1 \times 0.1}{0.8} \frac{P}{100}$$

$$P = 0.00042 \times \frac{0.8}{0.1 \times 0.1} \times 100 = \mathbf{3.36\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.95

Repeat the previous problem assuming the argon constitutes 1% of a gas mixture where we neglect any reactions of the other gases and find the pressure that will give a mole-concentration of Ar^+ of 0.1%.

Previous problem:

At 10 000 K the ionization reaction for Ar is: $Ar \Leftrightarrow Ar^+ + e^-$ with equilibrium constant of $K = 4.2 \times 10^{-4}$. What should the pressure be for a mole concentration of argon ions (Ar^+) of 10%?

	Ar	$\Leftrightarrow$ Ar^+	$+ e^-$	others	
Initial:	0.01	0	0	0.99	
Change	-x	x	x	0	
Final	0.01-x	x	x	0.99	Total = 1 + x

From the reaction (ionization) we recognize that the concentration of electrons must equal that of argon ions so

$$y_{Ar^+} = y_{e^-} = 0.001 = x / (1+x) \quad \Rightarrow \quad x = 0.001001$$

$$y_{Ar} = (0.01 - x) / (1 + x) = 0.00899$$

Now

$$K = 4.2 \times 10^{-4} = \frac{y_{Ar^+}\, y_{e^-}}{y_{Ar}} \left(\frac{P}{P^o}\right)^{1+1-1} = \frac{0.001 \times 0.001}{0.00899} \frac{P}{100}$$

$$P = 0.00042 \times 8990 \times 100 = \mathbf{377\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.96

Operation of an MHD converter requires an electrically conducting gas. It is proposed to use helium gas "seeded" with 1.0 mole percent cesium, as shown in Fig. P14.96. The cesium is partly ionized ($Cs \Leftrightarrow Cs^+ + e^-$) by heating the mixture to 1800 K, 1 MPa, in a nuclear reactor to provide free electrons. No helium is ionized in this process, so that the mixture entering the converter consists of He, Cs, Cs^+, and e^-. Determine the mole fraction of electrons in the mixture at 1800 K, where ln K = 1.402 for the cesium ionization reaction described.

Reaction:	$Cs \Leftrightarrow Cs^+ + e^-$,	Also He			ln K = 1.402
initial	0.01	0	0	0.99	=> K = 4.0633
change	-x	+x	+x	0	
Equil	(0.01-x)	x	x	0.99 ;	total: 1 + x

$$K = \frac{y_{e-}\, y_{Cs+}}{y_{Cs}} \left(\frac{P}{P^0}\right) = \left(\frac{x}{0.01 - x}\right)\left(\frac{x}{1 + x}\right)\left(\frac{P}{P^0}\right)$$

$$\text{or} \quad \left(\frac{x}{0.01 - x}\right)\left(\frac{x}{1 + x}\right) = 4.0633 / (1/0.1) = 0.40633$$

Quadratic equation: $x = 0.009767$

$$\Rightarrow \quad y_{e-} = \frac{x}{1 + x} = \mathbf{0.00967}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.97

One kilomole of argon gas at room temperature is heated to 20 000 K, 100 kPa. Assume that the plasma in this condition consists of an equilibrium mixture of Ar, Ar^+, Ar^{++}, and e^- according to the simultaneous reactions

(1) $Ar \Leftrightarrow Ar^+ + e^-$ (2) $Ar^+ \Leftrightarrow Ar^{++} + e^-$

The ionization equilibrium constants for these reactions at 20 000 K have been calculated from spectroscopic data as $\ln K_1 = 3.11$ and $\ln K_2 = -4.92$. Determine the equilibrium composition of the plasma.

1) $Ar \Leftrightarrow Ar^+ + e^-$ 2) $Ar^+ \Leftrightarrow Ar^{++} + e^-$

ch. -a +a +a ch. -b +b +b

Equil. Comp.: $n_{Ar} = 1-a$, $n_{Ar+} = a-b$, $n_{Ar++} = b$, $n_{e-} = a+b$, $n_{TOT} = 1+a+b$

$$K_1 = \frac{y_{Ar+}y_{e-}}{y_{Ar}}\left(\frac{P}{P^0}\right) = \frac{(a - b)(a + b)}{(1 - a)(1 + a + b)}(1) = 22.421$$

$$K_2 = \frac{y_{Ar++}y_{e-}}{y_{Ar+}}\left(\frac{P}{P^0}\right) = \frac{b(a + b)}{(a - b)(1 + a + b)}(1) = 0.0073$$

By trial & error: $a = 0.978\ 57$, $b = 0.014\ 13$

$n_{Ar} = 0.02143$, $n_{Ar+} = 0.96444$, $n_{Ar++} = 0.01413$, $n_{e-} = 0.9927$

$y_{Ar} = 0.0107$, $y_{Ar+} = 0.484$, $y_{Ar++} = 0.0071$, $y_{e-} = 0.4982$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.98

At 10 000 K the two ionization reactions for N and Ar as

1: $Ar \Leftrightarrow Ar^+ + e^-$ 2: $N \Leftrightarrow N^+ + e^-$

have equilibrium constants of $K_1 = 4.2 \times 10^{-4}$ and $K_2 = 6.3 \times 10^{-4}$, respectively. If we start out with 1 kmol Ar and 0.5 kmol N_2, what is the equilibrium composition at a pressure of 10 kPa?

At 10 000 K we assume all the nitrogen is dissociated to N.

Assume we shift the argon ionization with a and the nitrogen ionization with b we get

	Ar	Ar^+	e^-	N	N^+	
Initial	1	0	0	1	0	
Change	-a	a	a + b	-b	b	
Final	1-a	a	a + b	1-b	b	Tot: 2 + a + b

$$K_1 = 4.2 \times 10^{-4} = \frac{y_{Ar^+} y_{e^-}}{y_{Ar}} \left(\frac{P}{P^0}\right) = \frac{a\,(a+b)}{(1-a)(2+a+b)} \left(\frac{10}{100}\right) \qquad (1)$$

$$K_2 = 6.3 \times 10^{-4} = \frac{y_{N^+} y_{e^-}}{y_N} \left(\frac{P}{P^0}\right) = \frac{b\,(a+b)}{(1-b)(2+a+b)} \left(\frac{10}{100}\right) \qquad (2)$$

Divide the second equation with the first to get

$$\frac{b}{(1-b)} \frac{(1-a)}{a} = \frac{K_2}{K_1} = 1.5 \quad \Rightarrow \quad \frac{b - ab}{a - ab} = 1.5$$

$$b - ab = 1.5\,a - 1.5\,ab \quad \Rightarrow \quad b = 1.5\,a - 0.5\,ab = a(1.5 - 0.5\,b)$$

$$a = \frac{b}{1.5 - 0.5\,b} \quad \text{trial and error on equation (1)}$$

$$a = 0.059 \quad \text{and} \quad b = 0.086$$

$n_{Ar} = 0.941$, $n_{Ar^+} = 0.059$, $n_N = 0.914$, $n_{N^+} = 0.086$, $n_{e^-} = 0.145$

$y_{Ar} = 0.439$, $y_{Ar^+} = 0.027$, $y_N = 0.426$, $y_{N^+} = 0.04$, $y_{e^-} = 0.068$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.99

Plot to scale the equilibrium composition of nitrogen at 10 kPa over the temperature range 5000 K to 15 000 K, assuming that N_2, N, N^+, and e^- are present. For the ionization reaction $N \Leftrightarrow N^+ + e^-$, the ionization equilibrium constant K has been calculated from spectroscopic data as

T [K]	10000	12 000	14 000	16 000
$100K$	0.0626	1.51	15.1	92

1) $N_2 \Leftrightarrow 2N$ change -a +2a

2) $N \Leftrightarrow N^+ + e^-$ change -b +b +b

Equil. Comp.: $n_{N2} = 1 - a$, $n_N = 2a - b$, $n_{N+} = b$, $n_{e-} = b$

EQ1: $$K_1 = \frac{y_N^2}{y_{N2}}\left(\frac{P}{P^0}\right) = \frac{(2a - b)^2}{(1 - a)(1 + a + b)}\left(\frac{P}{P^0}\right)$$

EQ2: $$K_2 = \frac{y_{N+}y_{e-}}{y_N}\left(\frac{P}{P^0}\right) = \frac{b^2}{(2a - b)(1 + a + b)}\left(\frac{P}{P^0}\right)$$

For T < 10 000 K: $b \sim 0$ so neglect EQ2: $\Rightarrow$ $$K_1 = \frac{4a^2}{(1-a^2)}\left(\frac{10}{100}\right)$$

To extrapolate K_1 above 6000 K: $$\ln K_1 \approx 16.845 - \frac{118\,260}{T}$$

(from values at 5000 K & 6000 K)

T(K)	K_1	a	y_N	y_{N2}
5000	0.0011	0.0524	0.0996	0.9004
6000	0.0570	0.3532	0.5220	0.4780
7000	0.9519	0.8391	0.9125	0.0875
8000	7.866	0.9755	0.9876	0.0124
10000	151.26	0.9987	0.9993	0.0007

For T > 10 000 K: $a \approx 1.0$ => $$K_2 = \frac{b^2}{(2-b)(2+b)}\left(\frac{10}{100}\right) = \frac{b^2}{(4-b^2)}\,0.1$$

T(K)	K_2	b	y_N	y_{N+}
10 000	6.26×10^{-4}	0.1577	0.8538	0.0731
12 000	1.51×10^{-2}	0.7244	0.4862	0.2659
14 000	0.151	1.5512	0.1264	0.4368
16 000	0.92	1.8994	0.0258	0.4871

Note that $b \approx 0$ is not a very good approximation in the vicinity of 10 000 K. In this region, it would be better to solve the original set simultaneously for a & b. The answer would be approximately the same.

14.101

Assume air is at 3000 K, 1 MPa. Find the time constant for the NO formation. Repeat for 2000 K, 800 kPa.

From the rate in Eq.14.40: $\tau_{NO} = 8 \times 10^{-16}\ T\ (P_o/P)^{1/2}\ \exp(\frac{58\ 300}{T})$

Case a: $\tau_{NO} = 8 \times 10^{-16} \times 3000\ (100/1000)^{1/2}\ \exp(\frac{58\ 300}{3000})$

$= \mathbf{2.09 \times 10^{-4}\ s} = 0.209$ ms

Case b: $\tau_{NO} = 8 \times 10^{-16} \times 2000\ (100/800)^{1/2}\ \exp(\frac{58\ 300}{2000})$

$= \mathbf{2.58\ s}$

Notice the significant difference in time constants.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.102

Consider air at 2600 K, 1 MPa. Find the equilibrium concentration of NO neglecting dissociations of oxygen and nitrogen.

1 kmol air (0.78 N_2, 0.21 O_2, 0.01 Ar) at 2600 K, 1 MPa.

N_2	+ O_2	$\Leftrightarrow$ 2 NO	Ar	$n_{N2} = 0.78 - x$
0.78	0.21	0	0.01	$n_{O2} = 0.21 - x$
-x	-x	+2x		$n_{NO} = 2x$, $n_{ar} = 0.01$
0.78–x	0.21–x	2x	0.01	$n_{tot} = 1.0$

From A.11 at 2600 K, $\ln K = -5.316$, $K = 0.0049124$

$$K = \frac{4x^2}{(0.78 - x)(0.21 - x)} \left(\frac{P}{P^0}\right)^0 \quad \Rightarrow$$

$$\frac{x^2}{(0.78 - x)(0.21 - x)} = \frac{0.0049124}{4} = 0.001228 \quad \text{and} \quad 0 < x < 0.21$$

Solve for x: $x = 0.0136$ $\Rightarrow$ $y_{NO} = \frac{2x}{1.0} =$ **0.0272**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.103

Redo the previous Problem but include the dissociation of oxygen and nitrogen.

1 kmol air (0.78 N_2, 0.21 O_2, 0.01 Ar) at 2600 K, 1 MPa.

(1) $O_2 <=> 2\ O$ $\quad \ln K = -7.52, \quad K_1 = 0.000542 = (y_O^2/y_{O2})\ P/P_o$

(2) $N_2 <=> 2\ N$ $\quad \ln K = -28.313, \quad K_2 = 5.056 \times 10^{-13} = (y_N^2/y_{N2})\ P/P_o$

(3) $N_2 + O_2 <=> 2\ NO$ $\quad \ln K = -5.316, \quad K_3 = 0.00491 = (y_{NO}^2/y_{N2}\ y_{O2})$

Call the shifts a,b,c respectively so we get

$n_{O2} = 0.21 - a - c, \quad n_O = 2a, \quad n_{N2} = 0.78 - b - c, \quad n_N = 2b,$

$n_{NO} = 2c, \quad n_{Ar} = 0.01, \quad n_{tot} = 1 + a + b$

From which the mole fractions are formed and substituted into the three equilibrium equations. The result is

$$0.000542 \times 0.1 = y_O^2/y_{O2} = 4a^2 / [(1+a+b)(0.21-a-c)]$$

$$5.056 \times 10^{-14} = y_N^2/y_{N2} = 4b^2 / [(1+a+b)(0.79-b-c)]$$

$$0.00491 = y_{NO}^2/y_{N2}\ y_{O2} = 4c^2 / [(0.79-b-c)(0.21-a-c)]$$

which give 3 eqs. for the unknowns (a,b,c). Trial and error assume b = a = 0 solve for c from the last eq. then for a from the first and finally given the (a,c) solve for b from the second equation. The order chosen according to expected magnitude $K_3 > K_1 > K_2$

$a = 0.001626, \ b = 0.99 \times 10^{-7}, \ c = 0.01355 \ =>$

$n_{O2} = 0.1948, \quad n_O = 0.00325, \quad n_{N2} = 0.7665, \quad n_N = 1.98 \times 10^{-7},$

$n_{NO} = 0.0271, \quad n_{Ar} = 0.01$

$y_{NO} = n_{NO} / n_{tot} = 0.0271 / 1.00165 =$ **0.02706**

Indeed it is a very small effect to include the additional dissociations.

14.104

Calculate the equilibrium constant for the first reaction in the Zeldovich mechanism at 2600 K, 500 kPa. Notice this is not listed in A.11.

The reaction and equilibrium constant are

$$O + N_2 \Leftrightarrow NO + N$$

$$\ln K = -\frac{\Delta G^0}{\bar{R}T}; \qquad \Delta G^0 = \Delta H^0 - T\Delta S^0$$

$$\Delta H^0 = \bar{h}_{NO} + \bar{h}_N - \bar{h}_O - \bar{h}_{N2} = (80034 + 90291) + (47860 + 472680) - (48216 + 249170) - 77963 = 315\ 516 \text{ kJ/kmol}$$

$$\Delta S^0 = \bar{s}_{NO} + \bar{s}_N - \bar{s}_O - \bar{s}_{N2}$$
$$= 282.822 + 198.322 - 206.714 - 261.615 = 12.815 \text{ kJ/kmol-K}$$

$$\Delta G^0 = 315\ 516 - 2600 \times 12.815 = 282\ 197 \text{ kJ/kmol}$$

$$\ln K = -\frac{\Delta G^0}{\bar{R}T} = -\frac{282\ 197}{8.314472 \times 2600} = -13.054, \qquad K = \mathbf{2.14 \times 10^{-6}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.105

Find the equilibrium constant for the reaction: $2NO + O_2 \Leftrightarrow 2NO_2$ from the elementary reaction in Table A.11 to answer these two questions. Which of the nitrogen oxides NO or NO_2 is the more stable at 25°C, 100 kPa? At what T do we have an equal amount of each?

The elementary reactions are the last two ones in Table A.11:

a) $N_2 + O_2 \Leftrightarrow 2\,NO$ b) $N_2 + 2O_2 \Leftrightarrow 2\,NO_2$

Actual reaction is : $c = b - a \quad \Rightarrow \quad \ln(K_c) = \ln(K_b) - \ln(K_a)$

At 25°C (approx. 300 K) Table A.11: $\ln(K_a) = -69.868$; $\ln(K_b) = -41.355$

so now:

$$\ln(K_c) = -41.355 + 69.868 = 28.5 \quad \Rightarrow \quad K_c = 2.4 \times 10^{12}$$

meaning reaction is pushed completely to the right and **NO_2 is the stable** compound. Assume we start at room T with 1 kmol NO_2: then

	NO	O_2	NO_2	TOT
start	0	0	1	
change	2x	x	-2x	
Final	2x	x	1-2x	1+x

Equal amount of each

$$y(NO) = \frac{2x}{1+x} = y(NO_2) = \frac{1-2x}{1+x} \quad \Rightarrow \quad x = 0.25$$

$$K(T) = \frac{(1-2x)^2}{4x^3} = \frac{0.5^2}{4 \times 0.25^3} = 4 \quad \Rightarrow \quad \ln(K) = 1.386$$

We quickly see

$\ln(K)$ at 500 K $= -30.725 + 40.449 = 9.724$

$\ln(K)$ at 1000 K $= -23.039 + 18.709 = -4.33$

Linear interpolation $T = 500 + 0.406 \times 500 =$ **703 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.106

If air at 300 K is brought to 2600 K, 1 MPa, instantly, find the formation rate of NO.

The formation rate of NO is given by Eqs.14.39-40 using the equilibrium concentration in Eq.14.41. If we assume NO formation takes place and that the oxygen and nitrogen have not dissociated their concentrations are (we neglect the argon)

$$N_2 + O_2 \Leftrightarrow 2\,NO$$

$$y_{NOe} = 2x, \quad y_{O2} = 0.21 - x \quad \text{and} \quad y_{N2} = 0.79 - x$$

At 2600 K from A.11

$$\ln K_4 = -5.316 \quad \Rightarrow \quad K_4 = 0.0049124$$

so then we have

$$y_{NOe} = 2x = [K_4\,(0.21 - x)\,(0.79 - x)\,]^{1/2} \quad \text{solve for } x = 0.0136$$

$$y_{NOe} = 2x = 0.0272$$

From the rate in Eq.14.40: $\tau_{NO} = 8 \times 10^{-16}\, T\, (P_o/P)^{1/2} \exp(\dfrac{58\,300}{T})$

$$\tau_{NO} = 8 \times 10^{-16} \times 2600\, (100/1000)^{1/2} \exp(\frac{58\,300}{2600}) = 0.0036 \text{ s}$$

The formation rate is

$$\frac{dy_{NO}}{dt} = \frac{y_{NOe}}{\tau_{NO}} = \frac{0.0272}{0.0036 \text{ s}} = \mathbf{7.56\ s^{-1}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.107

Estimate the concentration of oxygen atoms in air at 3000 K, 100 kPa and 0.0001 kPa, Compare this to the result in Fig. 14.11.

For the dissociation of oxygen and nitrogen we get from A.11

O_2: $\ln K = -4.356$, N_2: $\ln K = -22.367$

from which it is evident that we need only to consider oxygen.

O_2	$\Leftrightarrow$	2 O	N_2	Ar	$n_{N2} = 0.78 - x$
0.21		0	0.78	0.01	$n_{O2} = 0.21 - x$
-x		+2x			$n_{NO} = 2x$, $n_{ar} = 0.01$
0.21–x		2x	0.78	0.01	$n_{tot} = 1 + x$

$$K(T) = \frac{y_O^2}{y_{O2}}\left(\frac{P}{P_o}\right)^{2-1} = \left(\frac{2x}{1+x}\right)^2 \frac{1+x}{0.21-x}\frac{P}{P_o} = \frac{4x^2}{1+x}\frac{1}{0.21-x}\frac{P}{P_o}$$

$$\Rightarrow \quad \frac{4x^2}{1+x}\frac{1}{0.21-x} = \frac{P_o}{P}K(T) = \frac{P_o}{P}\exp(-4.356)$$

P = 100 kPa: RHS = 0.01283 $\Rightarrow$ $x = 0.0247$, $y_O = \dfrac{2x}{1+x} = 0.0482$

P = 0.0001 kPa: RHS = 12830 $\Rightarrow$ $x = 0.21$, $y_O = \dfrac{2x}{1+x} = 0.347$

We notice from Fig. 14.11 that at 3000 K all the oxygen is dissociated so

$n_O / n_{\text{atoms in air}} = 0.21$ so $n_O = 0.42$, $y_O = 0.42/1.21 = 0.347$

since air is mainly diatomic so $n_{\text{atoms in air}} \approx 2$ (scale is confusing).

14.109

In a test of a gas-turbine combustor, saturated-liquid methane at 115 K is to be burned with excess air to hold the adiabatic flame temperature to 1600 K. It is assumed that the products consist of a mixture of CO_2, H_2O, N_2, O_2, and NO in chemical equilibrium. Determine the percent excess air used in the combustion, and the percentage of NO in the products.

$$CH_4 + 2x\,O_2 + 7.52x\,N_2 \rightarrow 1\,CO_2 + 2\,H_2O + (2x-2)\,O_2 + 7.52x\,N_2$$

Then	N_2	O_2	$\Leftrightarrow$	2 NO	Also	CO_2	H_2O
initial	7.52x	2x-2		0		1	2
change	-a	-a		+2a		0	0
final	(7.52x-a)	(2x-2-a)		2a		1	2

$$n_{TOT} = 1 + 9.52x$$

1600 K in A.11: $\ln K = -10.55$, $K = 2.628\times10^{-5}$

$$2.628\times10^{-5}\,K = \frac{y_{NO}^2}{y_{N2}y_{O2}}\left(\frac{P}{P^0}\right)^0 = \frac{y_{NO}^2}{y_{N2}y_{O2}} = \frac{4a^2}{(7.52x - a)(2x - 2 - a)}$$

From A.9 and B.7,

$$H_R = 1\left[-74\,873 + 16.043(-274.7-624.1)\right] + 0 + 0 = -89\,292\ \text{kJ}$$

(Air assumed 25 ^oC)

$$H_P = 1(-393\,522 + 67\,569) + 2(-241\,826 + 52\,907)$$
$$+ (7.52x-a)(41\,904) + (2x-2-a)(44\,267) + 2a(90\,291 + 43\,319)$$
$$= -792\,325 + 403\,652\,x + 181\,049\,a$$

Assume $a \sim 0$, then from $H_P - H_R = 0 \rightarrow x = 1.7417$ and substitute

$$\frac{a^2}{(13.098 - a)(1.483 - a)} = \frac{2.628\times10^{-5}}{4}, \qquad \text{get} \quad a \approx 0.0113$$

Use this a in the energy equation

$$x = \frac{703\,042 - 181\,049\times0.0113}{403\,652} = 1.7366$$

$$\Rightarrow \frac{a^2}{(13.059-a)(1.4732-a)} = \frac{2.628\times10^{-5}}{4},\ a = 0.0112 \quad \Rightarrow \quad x = 1.7366$$

% excess air = **73.7 %**

$$\%\ \text{NO} = \frac{2\times0.0112\times100}{1+9.52\times1.7366} = \mathbf{0.128\ \%}$$

14.110

Find the equilibrium constant for the reaction in Problem 14.92.

Reaction: $2\,CO + 2\,H_2 \Leftrightarrow CH_4 + CO_2$

Equilibrium constant Eq. 14.15: $\ln K = -\Delta G^0 / \bar{R}T$

For CH_4 at 600 K (formula in Table A.6), $\bar{C}_{P0} = 52.22$

At 900 K

$\bar{h}^0_{CH4} = -74\,873 + 52.22(900 - 298.2) = -43\,446$ kJ/kmol

$\bar{s}^0_{CH4} = 186.251 + 52.22 \ln (900 / 298.2) = 243.936$ kJ/kmol K

(The integrated-equation values are -43 656 and 240.259)

$\Delta H^0_{900\,K} = 1(-43\,446) + 1(-393\,522 + 28\,030)$

$- 2(-110\,527 + 18\,397) - 2(0 + 17\,657) = -259\,993$ kJ

$\Delta S^0_{900\,K} = 1(243.936) + 1(263.646)$

$- 2(231.074) - 2(163.060) = -280.687$ kJ/K

$\Delta G^0_{900\,K} = -259\,993 - 900(-280.687) = -7375$ kJ

$$\ln K = \frac{+7375}{8.3145 \times 900} = 0.9856, \qquad K = \mathbf{2.679}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.111

A space heating unit in Alaska uses propane combustion is the heat supply. Liquid propane comes from an outside tank at -44°C and the air supply is also taken in from the outside at -44°C. The airflow regulator is misadjusted, such that only 90% of the theoretical air enters the combustion chamber resulting in incomplete combustion. The products exit at 1000 K as a chemical equilibrium gas mixture including only CO_2, CO, H_2O, H_2, and N_2. Find the composition of the products.

Hint: use the water gas reaction in Example 14.4.

Propane: Liquid, $T_1 = -44^oC = 229.2$ K

Air: $T_2 = -44^oC = 229.2$ K, 90% Theoretical Air

Products: $T_3 = 1000$ K, CO_2, CO, H_2O, H_2, N_2

Theoretical Air: $C_3H_8 + 5O_2 + 18.8N_2 \Rightarrow 3CO_2 + 4H_2O + 18.8N_2$

90% Theoretical Air:

$$C_3H_8 + 4.5O_2 + 16.92N_2 \Rightarrow aCO_2 + bCO + cH_2O + dH_2 + 16.92N_2$$

Carbon: $a + b = 3$; Hydrogen: $c + d = 4$

Oxygen: $2a + b + c = 9$ Where: $2 \le a \le 3$

Reaction: $CO + H_2O \leftrightarrow CO_2 + H_2$

Initial:	b	c	a	d
Change:	-x	-x	x	x
Equil:	b - x	c - x	a + x	d + x

Chose an Initial guess such as: a = 2, b = 1, c = 4, d = 0

Note: A different initial choice of constants will produce a different value for x, but will result in the same number of moles for each product.

$$n_{CO2} = 2 + x, \quad n_{CO} = 1 - x, \quad n_{H2O} = 4 - x, \quad n_{H2} = x, \quad n_{N2} = 16.92$$

The reaction can be broken down into two known reactions to find K

(1) $2CO_2 \leftrightarrow 2CO + O_2$ @ 1000 K $\ln(K_1) = -47.052$

(2) $2H_2O \leftrightarrow 2H_2 + O_2$ @ 1000 K $\ln(K_2) = -46.321$

For the overall reaction: $\ln K = (\ln(K_2) - \ln(K_1))/2 = 0.3655$; $K = 1.4412$

$$K = \frac{y_{CO2}y_{H2}}{y_{CO}y_{H2O}}\left(\frac{P}{P_o}\right)^{1+1-1-1} = \frac{y_{CO2}y_{H2}}{y_{CO}y_{H2O}} = 1.4412 = \frac{(2+x)x}{(1-4)(4-x)}$$

$\Rightarrow x = 0.6462$

$n_{CO2} = 2.6462$ **$n_{CO} = 0.3538$** **$n_{N2} = 16.92$**

$n_{H2O} = 3.3538$ **$n_{H2} = 0.6462$**

$y_{CO2} = 0.111$, $y_{CO} = 0.015$, $y_{N2} = 0.707$, $y_{H2O} = 0.140$, $y_{H2} = 0.027$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.112

Derive the van't Hoff equation given in problem 14.56, using Eqs.14.12 and 14.15. Note: the d($\bar{g}$/T) at constant P for each component can be expressed using the relations in Eqs. 12.18 and 12.19.

Eq. 14.12: $\Delta G^0 = \nu_C \bar{g}_C^0 + \nu_D \bar{g}_D^0 - \nu_A \bar{g}_A^0 - \nu_B \bar{g}_B^0$

Eq. 14.15: $\ln K = -\Delta G^0 / \bar{R}T$ Eq. 14.19: $\Delta G^0 = \Delta H° - T\,\Delta S^0$

$$\frac{d\ln K}{dT} = -\frac{d}{dT}\left(\frac{\Delta G^0}{\bar{R}T}\right) = -\frac{1}{\bar{R}T}\frac{d\Delta G^0}{dT} + \frac{\Delta G^0}{\bar{R}T^2} = \frac{1}{\bar{R}T^2}\left[\Delta G^0 - T\frac{d\Delta G^0}{dT}\right]$$

$$= \frac{1}{\bar{R}T^2}[\Delta G^0 + T\,\Delta S^0] \qquad \text{used Eq.12.19} \qquad \frac{d\bar{g}}{dT} = -\bar{s}$$

$$= \frac{1}{\bar{R}T^2}\Delta H^0$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.113

Find the equilibrium constant for reaction in Eq. 14.33 at 600 K (see Problem 14.88).

Reaction: $CO + 3\,H_2 \Leftrightarrow CH_4 + H_2O$

Equilibrium constant Eq. 14.15: $\ln K = -\Delta G^0 / \bar{R}T$

For CH_4 at 600 K (formula in Table A.6), $\bar{C}_{P0} = 52.22$, A.5: $\bar{C}_{P0} = 36.16$

So use the average for the interval 298 – 600 K, $\bar{C}_{P0} = 44.19$ kJ/kmol-K

At 600 K

$\bar{h}^0_{CH4} = -74\,873 + 44.19(600 - 298.15) = -61\,534$ kJ/kmol

$\bar{s}^0_{CH4} = 186.251 + 44.19 \ln (600 / 298.15) = 217.154$ kJ/kmol K

$\Delta H^0_{600\,K} = 1(-61\,534) + 1(-241\,826 + 10\,499)$

$- (-110\,527 + 8\,942) - 3(0 + 8\,799) = -217\,673$ kJ

$\Delta S^0_{600\,K} = 1(217.154) + 1(213.051) - (218.321) - 3(151.078)$

$= -241.35$ kJ/K

$\Delta G^0_{600\,K} = -217\,673 - 600(-241.35) = -72\,863$ kJ

$$\ln K = -\frac{-72\,863}{8.3145 \times 600} = 14.6, \qquad K = \mathbf{2.2 \times 10^6}$$

Comment: If $\bar{C}_{P0}$ at 298 K for CH_4 was used then $K = 1.83 \times 10^6$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the b1976 United States Copyright Act without the permission of the copyright owner is unlawful.

14.114

Combustion of stoichiometric benzene, C_6H_6, and air at 80 kPa with a slight heat loss gives a flame temperature of 2400 K. Consider the dissociation of CO_2 to CO and O_2 as the only equilibrium process possible. Find the fraction of the CO_2 that is dissociated.

Combustion: $C_5H_{12} + 7.5\ O_2 + 7.5 \times 3.76\ N_2 \rightarrow 6\ CO_2 + 3\ H_2O + 28.2\ N_2$

	$2\ CO_2 \Leftrightarrow$	$2\ CO$	$+\ 1\ O_2$	also H_2O	N_2
Initial	6	0	0	3	28.2
Change	-2z	+2z	+z	0	0
Equil.	6-2z	2z	z	3	28.2

At 2400 K, $\ln K = -7.715$, $K = 4.461 \times 10^{-4}$ and we have $n_{tot} = 37.2 + z$

Substitute into equilibrium equation,

$$K = \frac{4z^2\ z}{(6 - 2z)^2(37.2 + z)} \left(\frac{80}{100}\right)^1 \Rightarrow \frac{z^3}{(3 - z)^2(37.2 + z)} = = 0.0005576$$

Solve with limit $0 < z < 3$ gives $z = 0.507$ so then $n_{CO_2} = 6 - 2z = 4.986$

Fraction dissociated = $(6 - 4.986)/6 =$ **0.169**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.115

One kilomole of liquid oxygen, O_2, at 93 K, and *x* kmol of gaseous hydrogen, H_2, at 25°C, are fed to a combustion chamber. *x* is greater than 2, such that there is excess hydrogen for the combustion process. There is a heat loss from the chamber of 1000 kJ per kmol of reactants. Products exit the chamber at chemical equilibrium at 3800 K, 400 kPa, and are assumed to include only H_2O, H_2, and O.

a. Determine the equilibrium composition of the products and also *x*, the amount of H_2 entering the combustion chamber.

b. Should another substance(s) have been included in part (a) as being present in the products? Justify your answer.

$$x\ H_2 + 1\ O_2 \rightarrow 2\ H_2O + (x - 2)\ H_2$$

(1) $1\ H_2O \Leftrightarrow 1\ H_2 + 1\ O$

shift -a +a +a and $a > 0$

Equil 2-a x-2+a a $a < 2$ and $n_{tot} = x + a$

(2) $2\ H_2O \Leftrightarrow 2\ H_2 + 1\ O_2$ $\ln K_2 = -1.906$

(3) $1\ O_2 \Leftrightarrow 2\ O$ $\ln K_3 = -0.017$

$\ln K_1 = 0.5(\ln K_2 + \ln K_3) = -0.9615 \Rightarrow K_1 = 0.3823$

Equil.: $$\frac{K_1}{(P/P_o)^1} = \frac{(x-2+a)a}{(2-a)(x+a)} = \frac{0.3823}{4} = 0.95575$$

Energy Eq.: $Q + H_R = H_P$, $Q = (1 + x)(-1000)$ kJ

Table A.9: $\Delta\bar{h}^*_{IG} = -5980$ kJ/kmol [or = 0.922×32(93-298.2) = -6054 kJ/kmol]

Fig. D.2: $T_r = 93/154.6 = 0.601$, $\Delta\bar{h}_f = -5.16 \times \bar{R} \times 154.6 = -6633$

$H_R = x(0 + 0) + 1(0 + \Delta\bar{h}^*_{IG} + \Delta\bar{h}_f) = 1(-5980 - 6633) = -12613$ kJ

$H_P = (2-a)(-241\,826 + 171\,981) + (x-2+a)(0 + 119077)$

$+ a(249170 + 73424) = 119077\ x + 511516\ a - 377844$

$= Q + H_R = -1000 - 1000\ x - 12613$

Rearrange eq. to: $x + 4.2599\ a = 3.03331$

Substitute it into the equilibrium eq.: $$\frac{(1.03331 + 5.2599\ a)\ a}{(2-a)(3.03331-3.2599\ a)} = 0.095575$$

Solve $a = 0.198$, LHS = 0.09547, **$x = 2.1898$**

$$y_{H2O} = \frac{2-a}{x+a} = 0.755, \quad y_{H2} = \frac{x-2+a}{x+a} = 0.162, \quad y_O = \frac{a}{x+a} = 0.083$$

Other substances and reactions: $2\ H_2O <=> H_2 + 2\ OH$, $\ln K = -0.984$,

$H_2 <=> 2\ H$, : $\ln K = 0.201$, $O_2 <=> 2\ O$, : $\ln K = -0.017$

All are significant as K's are of order 1.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.116

Dry air is heated from 25°C to 4000 K in a 100-kPa constant-pressure process. List the possible reactions that may take place and determine the equilibrium composition. Find the required heat transfer.

Air assumed to be 21% oxygen and 79% nitrogen by volume.

From the elementary reactions we have at 4000 K (A.11)

(1) $O_2 <=> 2\ O$ $\quad K_1 = 2.221 = y_O^2/y_{O2}$

(2) $N_2 <=> 2\ N$ $\quad K_2 = 3.141 \times 10^{-6} = y_N^2/y_{N2}$

(3) $N_2 + O_2 <=> 2\ NO$ $\quad K_3 = 0.08955 = y_{NO}^2/y_{N2}\, y_{O2}$

Call the shifts a,b,c respectively so we get

$$n_{O2} = 0.21 - a - c, \quad n_O = 2a, \quad n_{N2} = 0.79 - b - c, \quad n_N = 2b,$$

$$n_{NO} = 2c, \quad n_{tot} = 1 + a + b$$

From which the mole fractions are formed and substituted into the three equilibrium equations. The result is

$$K_1 = 2.221 = y_O^2/y_{O2} = 4a^2 / [(1+a+b)(0.21-a-c)]$$

$$K_2 = 3.141 \times 10^{-6} = y_N^2/y_{N2} = 4b^2 / [(1+a+b)(0.79-b-c)]$$

$$K_3 = 0.08955 = y_{NO}^2/y_{N2}\, y_{O2} = 4c^2 / [(0.79-b-c)(0.21-a-c)]$$

which give 3 eqs. for the unknowns (a,b,c). Trial and error assume b = c = 0 solve for a from K_1 then for c from K_3 and finally given the (a,c) solve for b from K_2. The order chosen according to expected magnitude $K_1 > K_3 > K_2$

$$a = 0.15, \ b = 0.000832, \ c = 0.0244 \ =>$$

$$n_{O2} = 0.0356, \ n_O = 0.3, \ n_{N2} = 0.765, \ n_N = 0.00167, \ n_{NO} = 0.049$$

$$Q = H_{ex} - H_{in} = n_{O2}\Delta\bar{h}_{O2} + n_{N2}\Delta\bar{h}_{N2} + n_O(\bar{h}_{fO} + \Delta\bar{h}_O)$$

$$+ n_N(\bar{h}_{fN} + \Delta\bar{h}_N) + n_{NO}(\bar{h}_{fNO} + \Delta\bar{h}_{NO}) - 0$$

$$= 0.0356 \times 138705 + 0.765 \times 130027 + 0.3(249170 + 77675)$$

$$+ 0.00167(472680 + 77532) + 0.049(90291 + 132671)$$

$$= \mathbf{214\ 306\ kJ/kmol\ air}$$

[If no reaction $\quad Q = n_{O2}\Delta\bar{h}_{O2} + n_{N2}\Delta\bar{h}_{N2} = 131\ 849$ kJ/kmol air]

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which the textbook has been adopted. 14.117

Saturated liquid butane (note: use generalized charts) enters an insulated constant pressure combustion chamber at 25°C, and *x* times theoretical oxygen gas enters at the same pressure and temperature. The combustion products exit at 3400 K. Assuming that the products are a chemical equilibrium gas mixture that includes CO, what is *x*?

Butane: $T_1 = 25^oC$, sat. liq., $x_1 = 0$, $T_c = 425.2$ K, $P_c = 3.8$ MPa

$T_{r1} = 0.7$, Figs. D.1and D.2, $P_{r1} = 0.10$, $P_1 = P_{r1}P_c = 380$ kPa

Fig D.2: $\left(\bar{h}_1^* - \bar{h}_1\right)_f = 4.85\ RT_c$

Oxygen: $T_2 = 25^oC$, X * theoretical air Products: $T_3 = 3400$ K

$$C_4H_{10} + 6.5X\ O_2 \Rightarrow 4\ CO_2 + 5\ H_2O + 6.5(X-1)\ O_2$$

$$2CO_2 \Leftrightarrow 2CO + O_2$$

	$2CO_2$	$2CO$	O_2	
Initial	4	0	6.5(X-1)	
Change	-2a	2a	a	
Equil.	4-2a	2a	6.5(X-1) + a	$n_{tot} = 2.5 + a + 6.5X$

$$n_{CO_2} = 4 - 2a,\quad n_{CO} = 2a,\quad n_{O_2} = 6.5(X-1) + a,\quad n_{H2O} = 5,$$

$$y_{CO} = \frac{2a}{2.5 + a + 6.5X},\quad y_{CO2} = \frac{4 - 2a}{2.5 + a + 6.5X},\quad y_{O2} = \frac{6.5(x - 1) + a}{2.5 + a + 6.5X}$$

The equilibrium constant is

$$K = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P_1}{P_o}\right)^{2+1-2} = \left(\frac{a}{2-a}\right)^2\left(\frac{6.5X - 6.5 + a}{6.5X - 2.5 + a}\right)\left(\frac{P_1}{P_o}\right)$$

@ $T_3 = 3400$ K Table A.11, $\ln(K) = 0.346$, $K = 1.4134$

$$1.4134 = \left(\frac{a}{2-a}\right)^2\left(\frac{6.5X - 6.5 + a}{6.5X - 2.5 + a}\right)(3.76) \qquad \text{Equation 1.}$$

Need a second equation:

Energy eq.: $Q_{CV} + H_R = H_P + W_{CV}$; $Q_{CV} = 0$, $W_{CV} = 0$

$$H_R = \left(\bar{h}_f^o + \Delta\bar{h}\right)_{C_4H_{10}} = (-126\ 200 - 17\ 146) = -143\ 346\ \text{kJ}$$

14.119E

Calculate the equilibrium constant for the reaction O_2 <=> 2O at temperatures of 537 R and 10 000 R.

Find the change in Gibbs function at the two T's from Table F.6:

537 R: $\Delta H^0 = 2\bar{h}^0_O - 1\bar{h}^0_{O2} = 2 \times 107\ 124 - 0 = 214\ 248$ Btu/lbmol;

$\Delta S^0 = 2\bar{s}^0_O - 1\bar{s}^0_{O2} = 2 \times 38.442 - 48.973 = 27.911$ Btu/lbmol R

$\Delta G^0 = \Delta H^0 - T\Delta S^0 = 214\ 248 - 537 \times 27.911 = 199\ 260$ Btu/lbmol

$$\ln K = -\frac{\Delta G^0}{\bar{R}T} = -\frac{+199\ 260}{1.98589 \times 537} = \mathbf{-185.85}$$

10 000 R: $\Delta H^0 = 2\bar{h}^0_O - 1\bar{h}^0_{O2} = 2\ (107\ 124 + 47\ 897) - 87\ 997$

$= 222\ 045$ Btu/lbmol;

$\Delta S^0 = 2\bar{s}^0_O - 1\bar{s}^0_{O2} = 2 \times 53.210 - 74.034 = 32.386$ Btu/lbmol R

$\Delta G^0 = \Delta H^0 - T\Delta S^0 = 222\ 045 - 10\ 000 \times 32.386 = -101\ 815$ Btu/lbmol

$$\ln K = -\frac{\Delta G^0}{\bar{R}T} = \frac{101\ 815}{1.98589 \times 10\ 000} = \mathbf{+5.127}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.120E

Consider the dissociation of oxygen, $O_2 \Leftrightarrow 2O$, starting with 1 lbmol oxygen at 77 F and heating it at constant pressure 1 atm. At which temperature will we reach a concentration of monatomic oxygen of 10%?

Look at initially 1 lbmol Oxygen and shift reaction with x

$$O_2 \Leftrightarrow 2\,O$$

Species	O_2	O	
Initial	1	0	
Change	-x	2x	
Equil.	1-x	2x	$n_{tot} = 1 - x + 2x = 1 + x$

$$y_O = \frac{2x}{1+x} = 0.1 \quad \Rightarrow \quad x = 0.1/(2 - 0.1) = 0.0526, \quad y_{O2} = 0.9$$

$$K = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{0.1^2}{0.9}\, 1.01325 = 0.011258 \quad \Rightarrow \quad \ln K = -4.487$$

Recall P_o = 100 kPa for Table A.11, $P/P_o = 101.325 / 100 = 1.01325$

Now look in Table A.11: T = **2982 K = 5368 R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.121E

Redo problem 14.120E for a total pressure of 0.4 atm.

Look at initially 1 lbmol Oxygen and shift reaction with x

$$O_2 \Leftrightarrow 2\,O$$

Species	O_2	O	
Initial	1	0	
Change	-x	2x	
Equil.	1-x	2x	$n_{tot} = 1 - x + 2x = 1 + x$

$$y_O = \frac{2x}{1+x} = 0.1 \quad \Rightarrow \quad x = 0.1/(2 - 0.1) = 0.0526, \quad y_{O2} = 0.9$$

$$K = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{0.1^2}{0.9} (1.01325 \times 0.4) = 0.004503 \quad \Rightarrow \quad \ln K = -5.403$$

Recall P_o = 100 kPa for Table A.11, $P/P_o = 101.325 / 100 = 1.01325$

Now look in Table A.11: T = **2857.6 K = 5143 R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.122E

Redo problem 14.120E, but start with 1 lbmol oxygen and 1 lbmol helium at 77 F, 1 atm.

Look at initially 1 mol Oxygen and shift reaction with x

$$O_2 \Leftrightarrow 2\,O$$

Species	O_2	O	He	
Initial	1	0	1	
Change	-x	2x		
Equil.	1-x	2x	1	$n_{tot} = 1 - x + 2x + 1 = 2 + x$

$$y_O = \frac{2x}{2 + x} = 0.1 \quad \Rightarrow \quad x = 0.2/(2 - 0.1) = 0.10526,$$

$$y_{O2} = (1 - x)/(2 + x) = 0.425$$

$$K = \frac{y_O^2}{y_{0_2}} \left(\frac{P}{P_o}\right)^{2-1} = \frac{0.1^2}{0.425}\, 1.01325 = 0.02384 \quad \Rightarrow \quad \ln K = -3.736$$

Recall P_o = 100 kPa for Table A.11, $P/P_o = 101.325 / 100 = 1.01325$

Now look in Table A.11: T = **3096 K = 5573 R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.123E

Pure oxygen is heated from 77 F to 5300 F in a steady flow process at a constant pressure of 30 lbf/in.^{2}. Find the exit composition and the heat transfer.

The only reaction will be the dissociation of the oxygen

$$O_2 \Leftrightarrow 2O \; ; \quad K(5300\ F) = K(3200\ K) = 0.046467$$

Look at initially 1 mol Oxygen and shift the above reaction with x

$$n_{O2} = 1 - x; \quad n_O = 2x; \quad n_{tot} = 1 + x; \quad y_i = n_i/n_{tot}$$

$$K = \frac{y_O^2}{y_{02}}\left(\frac{P}{P_o}\right)^{2-1} = \frac{4x^2}{(1+x)^2}\frac{1+x}{1-x}2 = \frac{8x^2}{1-x^2}$$

$$x^2 = \frac{K/8}{1 + K/8} \Rightarrow x = 0.07599; \quad y_{02} = \mathbf{0.859}; \quad y_0 = \mathbf{0.141}$$

$$\bar{q} = n_{02ex}\bar{h}_{02ex} + n_{0ex}\bar{h}_{Oex} - \bar{h}_{02in} = (1 + x)(y_{02}\bar{h}_{02} + y_0\bar{h}_O) - 0$$

$$\bar{h}_{02} = 45\ 581; \quad \bar{h}_O = 107124 + 26125 = 133\ 249$$

$$\bar{q} = 1.076(0.859 \times 45581 + 0.141 \times 133249) = 62\ 345\ \text{Btu/lbmol}\ O_2$$

$$q = \bar{q}/32 = \mathbf{1948\ Btu/lbm} \quad (= 1424 \text{ if no dissociation})$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.124E

Find the equilibrium constant for $CO_2 \Leftrightarrow CO + ½\ O_2$ at 3960 R using Table A.11.

The elementary reaction in A.11 is : $2CO_2 \Leftrightarrow 2CO + O_2$

so the wanted reaction is (1/2) times that and T = 3960 R = 2200 K so

$$K = K_{A.11}^{1/2} = \sqrt{\exp(-10.232)} = \exp(-5.116) = 0.006$$

or

$$\ln K = 0.5 \ln K_{A.11} = 0.5\ (-10.232) = -5.116$$

$$K = \exp(-5.11) = 0.006$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.125E

Assume we have air at 4 atm, 3600 R (as 21% O_2 and 79% N_2), and we can neglect dissociations of O_2 and N_2. What is the equilibrium mole fraction of NO? Find the enthalpy difference in the gases due to the formation of NO.

Air initially: $0.79\ N_2 + 0.21\ O_2$

Final mix: $(0.79 - x)\ N_2 + (0.21 - x)\ O_2 + 2x\ NO$

$N_2 + O_2 \Leftrightarrow 2\ NO$

$-x \quad -x \quad +2x$

$n_{N2} = 0.79 - x$

$n_{O2} = 0.21 - x$

$n_{NO} = 0 + 2x$

$n = 1.0$

From Table A.11, T = 3600 R = 2000 K, ln K = - 7.825

$$K = \frac{y_{NO}^2}{y_{N2} y_{O2}} \left(\frac{P}{P^0}\right)^0 = \frac{4x^2}{(0.79 - x)(0.21 - x)} = \exp(-7.825) = 0.0003996$$

So

$$x^2 = 0.000099904\ (0.79 - x)(0.21 - x) \quad \Rightarrow \quad x = 0.00402$$

$y_{NO} = 2x =$ **0.00804**

$\Delta H = 2x\ h_{NO} - x h_{N2} - x h_{O2}$ all at 3600 R

$= 0.00402\ [2 \times (38\,818 + 24\,875) - 24\,135 - 25441]$ Btu/lbmol

= **312.8 Btu/lbmol air**

14.126E

Air (assumed to be 79% nitrogen and 21% oxygen) is heated in a steady flow process at a constant pressure of 14.7 lbf/in.^{2}, and some NO is formed. At what temperature will the mole fraction of NO be 0.001?

$0.79N_2 + 0.21O_2$ heated at 14.7 lbf/in^2, forms NO

At exit, $y_{NO} = 0.001$

$N_2 + O_2 \Leftrightarrow 2\,NO$

$-x \quad -x \quad +2x$

$n_{N2} = 0.79 - x$

$n_{O2} = 0.21 - x$

$n_{NO} = 0 + 2x$

$n = 1.0$

$$y_{NO} = 0.001 = \frac{2x}{1.0} \Rightarrow \quad x = 0.0005 \quad \Rightarrow \quad n_{N2} = 0.7895, \quad n_{O2} = 0.2095$$

$$K = \frac{y_{NO}^2}{y_{N2} y_{O2}} \left(\frac{P}{P^0}\right)^0 = \frac{10^{-6}}{0.7895 \times 0.2095} = 6.046 \times 10^{-6} \quad \text{or} \quad \ln K = -12.016$$

From Table A.11, T = 1444 K = **2600 R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.127E

The combustion products from burning pentane, C_5H_{12}, with pure oxygen in a stoichiometric ratio exists at 4400 R. Consider the dissociation of only CO_2 and find the equilibrium mole fraction of CO.

$$C_5H_{12} + 8\ O_2 \rightarrow 5\ CO_2 + 6\ H_2O$$

At 4400 R,

ln K = -7.226

$K = 7.272 \times 10^{-4}$

$2\ CO_2 \Leftrightarrow 2\ CO + 1\ O_2$

	CO_2	CO	O_2
Initial	5	0	0
Change	-2z	+2z	+z
Equil.	5-2z	2z	z

Assuming $P = P^o = 0.1$ MPa,

$$K = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P}{P^0}\right) = \left(\frac{2z}{5 - 2z}\right)^2 \left(\frac{z}{5 + z}\right)(1) = 7.272 \times 10^{-4};$$

Trial & error on z: z = 0.2673

$n_{CO_2} = 4.4654$; $n_{CO} = 0.5346$; $n_{O_2} = 0.2673$

y_{CO} = **0.1015**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.128E

Pure oxygen is heated from 77 F, 14.7 lbf/in.^{2} to 5300 F in a constant volume container. Find the final pressure, composition, and the heat transfer

As oxygen is heated it dissociates

$$O_2 \Leftrightarrow 2O \qquad \ln K_{eq} = -3.069$$

C. V. Heater: $U_2 - U_1 = {}_1Q_2 = H_2 - H_1 - P_2v + P_1v$

Per mole O_2: ${}_1\bar{q}_2 = \bar{h}_2 - \bar{h}_1 + \bar{R}(T_1 - (n_2/n_1)T_2)$

Shift x in reaction final composition: $(1 - x)O_2 + 2xO$

$$n_1 = 1 \qquad n_2 = 1 - x + 2x = 1 + x$$

$$y_{O2} = (1 - x)/(1 + x) \; ; \quad y_O = 2x/(1 + x)$$

Ideal gas and $V_2 = V_1 \Rightarrow P_2 = P_1 n_2 T_2/n_1 T_1 \Rightarrow P_2/P_o = (1 + x)T_2/T_1$

Substitute the molefractions and the pressure into the equilibrium equation

$$K_{eq} = e^{-3.069} = \frac{y_O^2}{y_{02}}\left(\frac{P_2}{P_o}\right) = \left(\frac{2x}{1 + x}\right)^2 \left(\frac{1 + x}{1 - x}\right) \left(\frac{1 + x}{1}\right) \left(\frac{T_2}{T_1}\right)$$

$$\Rightarrow \frac{4x^2}{1 - x} = \frac{T_1}{T_2} e^{-3.069} = 0.00433 \Rightarrow x = 0.0324$$

$(n_{O2})_2 = 0.9676, \quad (n_O)_2 = 0.0648, \quad n_2 = 1.0324$

$$P_2 = P_o\,(1 + x)T_2/T_1 = 14.7\,(1 + 0.0324)\,\frac{5760}{460 + 77} = \mathbf{162.8\ psia}$$

${}_1\bar{q}_2 = 0.9676(45\,581) + 0.0648(107\,124 + 26\,125) - 0$

$$+ 1.98589(536.67 - 1.0324 \times 5760) = \mathbf{41\,996\ Btu/lbmol\ O_2}$$

$y_{O2} = 0.9676 / 1.0324 = \mathbf{0.937}$; $\quad y_O = 0.0648/1.0324 = \mathbf{0.0628}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.129E

Assume the equilibrium mole fractions of oxygen and nitrogen are close to those in air, find the equilibrium mole fraction for NO at 5400 R, 75 psia disregarding dissocoiations.

Assume the simple reaction to make NO as:

N_2	+ O_2	$\Leftrightarrow$ 2 NO	Ar	$n_{N2} = 0.78 - x$
0.78	0.21	0	0.01	$n_{O2} = 0.21 - x$
-x	-x	+2x		$n_{NO} = 2x$, $n_{ar} = 0.01$
0.78–x	0.21–x	2x	0.01	$n_{tot} = 1.0$

From A.11 at 5400 R = 3000 K, ln K = -4.205, K = 0.014921

$$K = \frac{4x^2}{(0.78 - x)(0.21 - x)} \left(\frac{P}{P^0}\right)^0 \quad \Rightarrow$$

$$\frac{x^2}{(0.78 - x)(0.21 - x)} = \frac{0.014921}{4} = 0.00373 \quad \text{and} \quad 0 < x < 0.21$$

Solve for x: x = 0.0230 $\Rightarrow$ $y_{NO} = \frac{2x}{1.0} =$ **0.046**

Comment: Since the reaction is pressure insensitive P does not matter.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.130E

Acetylene gas, C_2H_2, is burned with stoichiometric air in a torch. The reactants are supplied at the reference conditions P_0, T_0. The products come out from the flame at 5000 R after a small heat loss by radiation. Consider the dissociation of CO_2 into CO and O_2 and no others. Find the equilibrium composition of the products. Are there any other reactions that should be considered?

Combustion: $C_2H_2 + 2.5\,(O_2 + 3.76N_2) \rightarrow 2\,CO_2 + 1\,H_2O + 9.4\,N_2$

At 5000 R = 2778 K

ln K = -3.9804

K = 0.01868

	$2\,CO_2 \Leftrightarrow 2\,CO + 1\,O_2$			H_2O	N_2
Initial	2	0	0	1	9.4
Change	-2z	+2z	+z	0	0
Equil.	2-2z	2z	z	1	9.4

Assuming $P = P^o = 0.1$ MPa, and $n_{tot} = 2 + z + 1 + 9.4 = 12.4 + z$

$$K = \frac{y_{CO}^2 y_{O_2}}{y_{CO_2}^2}\left(\frac{P}{P^0}\right) = \left(\frac{2z}{2 - 2z}\right)^2 \left(\frac{z}{12.4 + z}\right)(1) = 0.01868;$$

Solve: $z^3 = 0.01868\,(1 - z)^2(12.4 + z) \quad \Rightarrow \quad z = 0.428$

$$y_{CO} = \frac{2z}{12.4 + z} = \mathbf{0.0667};\ y_{CO2} = \frac{2 - 2z}{12.4 + z} = \mathbf{0.089};\ y_{O2} = \frac{z}{12.4 + z} = \mathbf{0.0334}$$

$$y_{H2O} = \frac{1}{12.4 + z} = \mathbf{0.0779};\quad y_{N2} = \frac{9.4}{12.4 + z} = \mathbf{0.7328}$$

Looking in A.11 there will be no dissociation of nitrogen and only a small dissociation of water and oxygen which could be included.

14.131E

Use the information in problem 14.142E to estimate the enthalpy of reaction, ΔH^o, at 1260 R using the van't Hoff equation (see problem 14.56) with finite differences for the derivatives.

$$d \ln K = \frac{\Delta H^o}{\bar{R} T^2} \, dT_p{}^o$$

solve for $\Delta H°$

$$\Delta H° = \bar{R} T^2 \frac{d\ln K}{dT} = \bar{R} T^2 \frac{\Delta \ln K}{\Delta T}$$

$$= 1.98589 \times 1260^2 \times \frac{-0.3362 + 4.607}{1440 - 1080} = 37\ 403 \text{ Btu/lb mol}$$

[Remark: compare this to F.6 values + F.4, F.11,

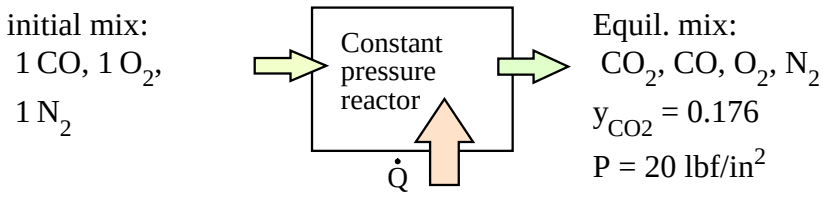
$$\Delta H° = H_C + 2H_{H_2} - H_{CH_4} = 0.146 \times 12 \times (1260\text{-}537) + 2 \times 5044$$

$$- 0.538 \times 16.043 \times (1260\text{-}537) \ \text{-}(\text{-}32190) = \mathbf{37\ 304}\ ]$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.132E

A gas mixture of 1 lbmol carbon monoxide, 1 lbmol nitrogen, and 1 lbmol oxygen at 77 F, 20 lbf/in.^{2}, is heated in a constant pressure steady flow process. The exit mixture can be assumed to be in chemical equilibrium with CO_2, CO, O_2, and N_2 present. The mole fraction of CO_2 at this point is 0.176. Calculate the heat transfer for the process.



reaction	$2\,CO_2$	$\Leftrightarrow$	$2\,CO$	+	O_2	also,	N_2
initial	0		1		1		1
change	+2x		-2x		-x		0
equil.	2x		(1-2x)		(1-x)		1

$$y_{CO2} = 0.176 = \frac{2x}{3\text{-}x} \quad \Rightarrow \quad x = 0.242\,65$$

$$\left.\begin{matrix} n_{CO2} = 0.4853 & n_{O2} = 0.757\,35 \\ n_{CO} = 0.5147 & n_{N2} = 1 \end{matrix}\right\} \Rightarrow \begin{cases} y_{CO2} = 0.176 \\ y_{CO} = 0.186\,67 \\ y_{O2} = 0.274\,67 \end{cases}$$

$$K = \frac{y_{CO}^2 y_{O2}}{y_{CO2}^2}\left(\frac{P}{P^0}\right)^1 = \frac{0.186\,67^2 \times 0.274\,67}{0.176^2}\left(\frac{20}{14.504}\right) = 0.426\,07$$

Since Table A.11 corresponds to a pressure P_0 of 100 kPa, which is 14.504 lbf/in^2. Then, from A.11, $T_{PROD} = 3200$ K = 5760 R

H_R = -47 518 Btu

H_P = 0.4853(-169 184 + 71 075) + 0.5147(-47 518 + 43 406)

+ 0.757 35(0 + 45 581) + 1(0 + 43 050) = +27 842 Btu

$Q_{CV} = H_P - H_R$ = 27 842 - (-47 518) = **+75 360 Btu**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.133E

Acetylene gas at 77 F is burned with 140% theoretical air, which enters the burner at 77 F, 14.7 lbf/in.^{2}, 80% relative humidity. The combustion products form a mixture of CO_2, H_2O, N_2, O_2, and NO in chemical equilibrium at 3500 F, 14.7 lbf/in.^{2}. This mixture is then cooled to 1340 F very rapidly, so that the composition does not change. Determine the mole fraction of NO in the products and the heat transfer for the overall process.

$$C_2H_2 + 3.5\,O_2 + 13.16\,N_2 + \text{water} \rightarrow$$

$$2\,CO_2 + 1\,H_2O + 1\,O_2 + 13.16\,N_2 + \text{water}$$

Water: $P_V = 0.8 \times 0.46 = 0.368$ lbf/in^2

$$n_V = n_A \times \frac{P_V}{P_A} = (3.5+13.16) \times \frac{0.368}{14.332} = 0.428$$

So, total H_2O in products is : $1 + n_V = 1.428$.

a) reaction: $N_2 + O_2 \Leftrightarrow 2\,NO$

change : -x -x +2x

at 3500 F = 3960 R (=2200 K), from A.11: K = 0.001 074

Equilibrium products:

$n_{CO2} = 2$, $n_{H2O} = 1.428$, $n_{O2} = 1 - x$,

$n_{N2} = 13.16 - x$, $n_{NO} = 0 + 2x$, $n_{TOT} = 17.588$

$$K = \frac{(2x)^2}{(1 - x)(13.16 - x)} = 0.001\,074$$

By trial and error, x = 0.0576

$$y_{NO} = \frac{2 \times 0.0576}{17.588} = \mathbf{0.006\,55}$$

b) Final products (same composition) at 1340 F = 1800 R

$H_R = 1(97\,476) + 0.428(-103\,966) = 52\,979$ Btu

$H_P = 2(-169\,184+14\,358) + 1.428(-103\,966+11\,178)$

$+ 0.9424(0+9761) + 13.1024(0+9227) + 0.1152(38\,818+9557)$

$= -306\,486$ Btu

$Q_{CV} = H_P - H_R =$ **-359 465 Btu**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.134E

A special coal burner uses a stoichiometric mixture of coal and an oxygen - argon mixture (1:1 mole ratio) with the reactants supplied at Po, To. Consider the dissociation of CO_2 into CO and O_2 and no others. Find the equilibrium composition of the products for T = 8600 R. Is the final temperature, including dissociations, higher or lower than 8600 R?

Combustion: $C + O_2 + Ar \Rightarrow CO_2 + Ar$

Reaction:

$2\,CO_2 \Leftrightarrow 2\,CO + O_2$

	CO_2	CO	O_2	Ar	
Start	1	0	0	1	
Change	-2x	2x	x	0	
Final	1-2x	2x	x	1	tot = 2 + x

At 8600 R: $K = \exp(5.7694) = 320.345$

$$K = [\, y_{CO}^2 \, y_{O2} / y_{CO2}^2]\, 1 = [(\frac{2x}{2+x})^2 \frac{x}{2+x} / (\frac{1-2x}{2+x})^2]$$

Reduce and solve:

$$x^3 = [\, \exp(5.7694)/4 \,]\,(2+x)\,(1-2x)^2$$

$$\Rightarrow \quad x^3 = 80.09\,(2+x)\,(1-2x)^2 \quad \Rightarrow \quad x = 0.48793$$

$n_{CO} = 0.9759,\ n_{O2} = 0.4879,\ n_{CO2} = 0.0241,\ n_{Ar} = 1$

Now we can do the energy equation:

$H_{P\ 8600\ R} = 0.0241\,(113\,961 - 169\,184) + 1 \times 4.9536\,(8600 - 459.7) +$

$0.9759\,(68\,977 - 47\,518) + 0.4879 \times 73\,648$

$= 95\,868$ btu/lbmol

Since $H_{P\ 8600\ R} > 0$ (too high) then **T < 8600 R**

We should have had $H_P = 0$, if we match the energy equation to find the T we have to redo the equilibrium equation as K is different. This is a larger trial and error problem to find the actual T and we even neglected other possible reactions.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.135E

An important step in the manufacture of chemical fertilizer is the production of ammonia, according to the reaction: $N_2 + 3H_2 \Leftrightarrow 2NH_3$. Show that the equilibrium constant is K = 6.826 at 300 F.

$$1N_2 + 3H_2 \Leftrightarrow 2NH_3 \qquad \text{at } 300 \text{ F} = 760 \text{ R}$$

from Table F.4 for NH_3: M = 17.031, C_{P0} = 0.509 Btu/lbm-R

Assume ideal gas and constant specific heat for ammonia (we could be more accurate if we used Table F.8 realizing properties depend also on P). We must use the reference h, s values from Table F.11

$$\bar{h}^{o}_{NH3\ 300\ F} = -19\ 656 + 0.509 \times 17.031\ (300\text{-}77) = -17723 \text{ Btu/lbmol}$$

$$\bar{s}^{o}_{NH3\ 300\ F} = 45.969 + 0.509 \times 17.031 \ln \frac{760}{537} = 48.980$$

Use Table F.6 for nitrogen and hydrogen gases

$$\Delta H^{o}_{300\ F} = 2(-17723) - 1(0 + 1557) - 3(0 + 1552) = -41\ 659 \text{ Btu/lbmol}$$

$$\Delta S^{0}_{300\ F} = 2(48.98) - 1(48.164) - 3(33.60) = -51.0 \text{ Btu/R-lbmol}$$

$$\Delta G^{0}_{300\ F} = -41\ 659 - 760(-51.0) = -2899 \text{ Btu/lbmol}$$

$$\ln K = \frac{+2899}{1.98589 \times 760} = 1.9208, \qquad K = \mathbf{6.826}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.136E

Consider the previous reaction in equilibrium at 300 F, 750 psia. For an initial composition of 25% nitrogen, 75% hydrogen, on a mole basis, calculate the equilibrium composition.

$$1N_2 + 3H_2 \Leftrightarrow 2NH_3 \text{ at } 300 \text{ F}$$

Beginning:	1	3	0	
Change:	-x	-3x	2x	
Final:	1-x	3-3x	2x	Total: $n = 4 - 2x$

$n_{NH3} = 2x, \quad n_{N2} = 1\text{-}x, \quad n_{H2} = 3\text{-}3x$

The reaction constant is $K = 6.826$ so the reaction constant equation is

$$K = \frac{y_{NH3}^2}{y_{N2} y_{H2}^3}\left(\frac{P}{P^0}\right)^{-2} = \frac{(2x)^2 2^2 (2\text{-}x)^2}{3^3 (1\text{-}x)^4}\left(\frac{P}{P^0}\right)^{-2}$$

$$\text{or } \left(\frac{x}{1\text{-}x}\right)^2 \left(\frac{2\text{-}x}{1\text{-}x}\right)^2 = \frac{27}{16} \times 6.826 \times \left(\frac{750}{14.7}\right)^2 = 29985$$

$$\text{or } \left(\frac{x}{1\text{-}x}\right)\left(\frac{2\text{-}x}{1\text{-}x}\right) = 173.16$$

$\rightarrow$ Trial & Error:

$x = 0.9242$

	n	y

14.137E

Ethane is burned with 150% theoretical air in a gas turbine combustor. The products exiting consist of a mixture of CO_2, H_2O, O_2, N_2, and NO in chemical equilibrium at 2800 F, 150 lbf/in.^{2}. Determine the mole fraction of NO in the products. Is it reasonable to ignore CO in the products?

Combustion:

$$C_2H_6 + 5.25\,O_2 + 19.74\,N_2 \rightarrow 2\,CO_2 + 3\,H_2O + 1.75\,O_2 + 19.74\,N_2$$

a) Products at 2800 F, 150 lbf/in^2. Equilibrium mixture: CO_2, H_2O, O_2, N_2, NO

	N_2	+	O_2	$\Leftrightarrow$	2 NO
initial	19.74		1.75		0
change	-x		-x		+2x
equil.	19.74-x		1.75-x		2x

Equil. comp. $n_{CO2} = 2$, $n_{H2O} = 3$, $n_{O2} = 1.75\text{-}x$, $n_{N2} = 19.74\text{-}x$, $n_{NO} = 2x$

$$K = 1.283\times10^{-4} = \frac{y_{NO}^2}{y_{N2}y_{O2}}\left(\frac{P}{P^0}\right)^0 = \frac{4x^2}{(19.74\text{-}x)(1.75\text{-}x)}$$

Solving, $x = 0.032\,95$

$$y_{NO} = \frac{2\times0.032\,95}{26.49} = \mathbf{0.002\,49}$$

b)

	$2\,CO_2$	$\Leftrightarrow$	2 CO	+	O_2
initial	2		0		0
change	-2a		+2a		+2x
equil.	2-2a		2a		2x

$$K = 5.259\times10^{-8} = \frac{y_{CO}^2 y_{O2}}{y_{CO2}^2}\left(\frac{P}{P^0}\right)^1 = \left(\frac{2a}{2\text{-}2a}\right)^2\left(\frac{1.75\text{-}x+a}{26.49+a}\right)\left(\frac{150}{14.504}\right)$$

Since Table A.11 corresponds to a pressure P_o of 100 kPa, which is 14.504 lbf/in^2. This equation should be solved simultaneously with the equation solved in part a) (modified to include the unknown a). Since x was found to be small and also a will be very small, the two are practically independent. Therefore, use the value $x = 0.032\,95$ in the equation above, and solve for a.

$$\left(\frac{a}{1\text{-}a}\right)^2\left(\frac{1.75\text{-}0.032\,95+a}{26.49+a}\right) = \left(\frac{14.504}{150}\right)\times5.259\times10^{-8}$$

Solving, $a = 0.000\,28$ or $y_{CO} = 2.1\times10^{-5}$ negligible for most applications.

14.138E

One pound mole of water vapor at 14.7 lbf/in.^{2}, 720 R, is heated to 5400 R in a constant pressure steady flow process. Determine the final composition, assuming that H_2O, H_2, H, O_2, and OH are present at equilibrium.

Reactions:

1) $2\,H_2O \Leftrightarrow 2\,H_2 + O_2$ 2) $2\,H_2O \Leftrightarrow H_2 + 2\,OH$

change -2a +2a +a change -2b +b +2b

3) $H_2 \Leftrightarrow 2\,H$

change -c +2c

At equilibrium (5400 R, 14.7 lbf/in^2)

n_{H2O} = 1-2a-2b n_{OH} = 2b

n_{H2} = 2a+b-c n_{H} = 2c

n_{O2} = a n_{TOT} = 1+a+b+c

$$\frac{K_1}{(P/P^0)} = \frac{2.062\times10^{-3}}{1.03} = \left(\frac{2a+b-c}{1-2a-2b}\right)^2\left(\frac{a}{1+a+b+c}\right)$$

$$\frac{K_2}{(P/P^0)} = \frac{2.893\times10^{-3}}{1.03} = \left(\frac{2a+b-c}{1+a+b+c}\right)\left(\frac{2b}{1-2a-2b}\right)^2$$

$$\frac{K_3}{(P/P^0)} = \frac{2.496\times10^{-2}}{1.03} = \frac{(2a)^2}{(2a+b-c)(1+a+b+c)}$$

These three equations must be solved simultaneously for

a, b & c: a = 0.0622, b = 0.0570, c = 0.0327

and $n_{H2O} = 0.7616$ $y_{H2O} = 0.6611$

$n_{H2} = 0.1487$ $y_{H2} = 0.1291$

$n_{O2} = 0.0622$ $y_{O2} = 0.0540$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.139E

Methane is burned with theoretical oxygen in a steady flow process, and the products exit the combustion chamber at 5300 F, 100 lbf/in.^{2}. Calculate the equilibrium composition at this state, assuming that only CO_2, CO, H_2O, H_2, O_2, and OH are present.

Combustion: $CH_4 + 2\,O_2 \rightarrow CO_2 + 2\,H_2O$

Dissociation reactions:

1) $2\,H_2O \Leftrightarrow 2\,H_2 + O_2$

change -2a +2a +a

2) $2\,H_2O \Leftrightarrow H_2 + 2\,OH$

change -2b +b +2b

3) $2\,CO_2 \Leftrightarrow 2\,CO + O_2$

change -2c +2c +c

At equilibrium:

n_{H2O} = 2-2a-2b

n_{H2} = 2a+b

n_{O2} = a+c

n_{OH} = 2b

n_{CO2} = 1-2c

n_{CO} = 2c

n_{TOT} = 3+a+b+c

Products at 5300F, 100 lbf/in^2

$$K_1 = 0.007\,328 = \left(\frac{2a+b}{2-2a-2b}\right)^2\left(\frac{a+c}{3+a+b+c}\right)\left(\frac{100}{14.504}\right)$$

$$K_2 = 0.012\,265 = \left(\frac{2b}{2-2a-2b}\right)^2\left(\frac{2a+b}{3+a+b+c}\right)\left(\frac{100}{14.504}\right)$$

$$K_3 = 0.426\,135 = \left(\frac{2c}{1-2c}\right)^2\left(\frac{a+c}{3+a+b+c}\right)\left(\frac{100}{14.504}\right)$$

These 3 equations must be solved simultaneously for a, b, & c. If solving by hand divide the first equation by the second, and solve for c = fn(a,b). This reduces the solution to 2 equations in 2 unknowns. Solving,

a = 0.0245, b = 0.1460, c = 0.2365

Substance:	H2O	H2	O2	OH	CO2	CO
n	1.659	0.195	0.260	0.292	0.527	0.473

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.140E

One pound mole of air (assumed to be 78% nitrogen, 21% oxygen, and 1% argon) at room temperature is heated to 7200 R, 30 lbf/in.^{2}. Find the equilibrium composition at this state, assuming that only N_2, O_2, NO, O, and Ar are present.

1 lbmol air (0.78 N_2, 0.21 O_2, 0.01 Ar) heated to 7200 R, 30 lbf/in^2.

1) $N_2 + O_2 \Leftrightarrow 2\,NO$ 2) $O_2 \Leftrightarrow 2\,O$

change	-a	-a	+2a	change	-b	+2b

Equil.:

n_{N2} =	0.78-a	n_{Ar} =	0.01	n_{NO} =	2a
n_{O2} =	0.21-a-b	n_O =	2b	n =	1+b

$$K_1 = 0.0895 = \frac{4a^2}{(0.78\text{-}a)(0.21\text{-}a\text{-}b)} \left(\frac{30}{14.504}\right)^0$$

$$K_2 = 2.221 = \frac{4b^2}{(1+b)(0.21\text{-}a\text{-}b)} \left(\frac{30}{14.504}\right)$$

Divide 1st eq'n by 2nd and solve for a as function(b), using

$$X = \frac{K_1}{K_2}\left(\frac{P}{P^0}\right) = 0.083\,35$$

Get

$$a = \frac{Xb^2}{2(1+b)}\left[-1 + \sqrt{1 + \frac{4\times 0.78(1+b)}{Xb^2}}\right] \qquad (1)$$

Also

$$\frac{b^2}{(1+b)(0.21\text{-}a\text{-}b)} = \frac{K_2}{4(P/P^0)} = 0.268\,44 \qquad (2)$$

Assume b = 0.1269 From (1), get a = 0.0299

Then, check a & b in (2) $\Rightarrow$ OK

Therefore,

Subst.	N2	O2	Ar	O	NO
n	0.7501	0.0532	0.01	0.2538	0.0598
y	0.6656	0.0472	0.0089	0.2252	0.0531

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.141E

Acetylene gas and x times theoretical air ($x > 1$) at room temperature and 75 lbf/in.^{2} are burned at constant pressure in an adiabatic steady flow process. The flame temperature is 4600 R, and the combustion products are assumed to consist of N_2, O_2, CO_2, H_2O, CO, and NO. Determine the value of x.

Combustion:

$$C_2H_2 + 2.5x\, O_2 + 9.4x\, N_2 \rightarrow 2\, CO_2 + H_2O + 2.5(x-1)O_2 + 9.4x\, N_2$$

Eq. products 4600 R, 75 lbf/in^2: N_2, O_2, CO_2, H_2O, CO, NO

2 Reactions:

1) $2\, CO_2 \Leftrightarrow 2\, CO + O_2$ change -2a +2a +a

2) $N_2 + O_2 \Leftrightarrow 2\, NO$ change -b -b +2b

Equil. Comp.:

n_{N2} =	9.4x-b	n_{CO2} =	2-2a
n_{O2} =	2.5x-2.5+a-b	n_{H2O} =	1
n_{CO} =	2a	n_{NO} =	2b
n_{TOT} =	11.9x+0.5+a		

At 4600 R, from A.11: $K_1 = 2.359\times10^{-3}$, $K_2 = 4.249\times10^{-3}$

$$\frac{K_1}{(P/P^0)} = \frac{2.359\times10^{-3}}{5.103} = 4.622\times10^{-4} = \left(\frac{a}{1-a}\right)^2\left(\frac{2.5x-2.5+a-b}{11.9x+0.5+a}\right)$$

$$K_2 = 4.249\times10^{-3} = \frac{(2b)^2}{(9.4-b)(2.5x-2.5+a-b)}$$

Also, from the energy Eq.: $H_P - H_R = 0$ where

$H_R = 1(+97\,477) + 0 + 0 = +97\,497$ Btu

$H_P = (9.4x-b)(0+32\,817) + (2.5x-2.5+a-b)(0+34\,605)$

$+ (2-2a)(-169\,184+53\,885) + 1(-103\,966+43\,899)$

$+ 2a(-47\,518+33\,122) + 2b(38\,818+31\,161)$

Substituting,

$$394\,992 \times x + 236\,411 \times a + 72\,536 \times b - 377\,178 = 97477$$

which results in a set of 3 equations in the 3 unknowns x,a,b. Trial and error solution from the last eq. and the ones for K_1 and K_2. The result is

x = 1.12 , a = 0.1182, b = 0.05963

14.142E

The equilibrium reaction with methane as $CH_4 \Leftrightarrow C + 2H_2$ has ln K = -0.3362 at 1440 R and ln K = -4.607 at 1080 R. By noting the relation of K to temperature, show how you would interpolate lnK in (1/T) to find K at 1260 R and compare that to a linear interpolation.

ln K = -0.3362 at 1440 R ln K = -4.607 at 1080 R

$$\ln K_{1260} = \ln K_{1440} + \frac{\frac{1}{1260} - \frac{1}{1440}}{\frac{1}{1080} - \frac{1}{1440}} \times (-4.607 + 0.3362)$$

$$= -0.3362 + \frac{\frac{1440}{1260} - 1}{\frac{1440}{1080} - 1} \times (-4.2708) = -2.1665$$

Linear interpolation:

$$\ln K_{1260} = \ln K_{1080} + \frac{1260 - 1080}{1440 - 1080} (\ln K_{1440} - \ln K_{1080})$$

$$= -4.607 + \frac{1}{2}(-0.3362 + 4.607) = \mathbf{-2.4716}$$

14.143E

In a test of a gas-turbine combustor, saturated-liquid methane at 210 R is to be burned with excess air to hold the adiabatic flame temperature to 2880 R. It is assumed that the products consist of a mixture of CO_2, H_2O, N_2, O_2, and NO in chemical equilibrium. Determine the percent excess air used in the combustion, and the percentage of NO in the products.

$$CH_4 + 2x\,O_2 + 7.52x\,N_2$$

$$\rightarrow 1\,CO_2 + 2\,H_2O + (2x-2)\,O_2 + 7.52x\,N_2$$

Then	N_2	+ O_2	$\Leftrightarrow$ 2 NO	Also	CO_2	H_2O
init	7.52x	2x-2	0		1	2
ch.	-a	-a	+2a		0	0
equil.	(7.52x-a)	(2x-2-a)	2a		1	2

$$n_{TOT} = 1 + 9.52x$$

2880 R: $\ln K = -10.55$, $K = 2.628\times10^{-5}$

$$2.628\times10^{-5}\,K = \frac{y_{NO}^2}{y_{N2}y_{O2}}\left(\frac{P}{P^0}\right)^0 = \frac{y_{NO}^2}{y_{N2}y_{O2}} = \frac{4a^2}{(7.52x-a)(2x-2-a)}$$

$$H_R = 1\left[-32\,190 + (-1854-4300)\right] + 0 + 0 \text{ (assume 77 F)} = -38\,344 \text{ Btu}$$

$$H_P = 1(-169\,184 + 29\,049) + 2(-103\,966 + 22\,746)$$

$$+ (7.52x-a)(18\,015) + (2x-2-a)(19\,031) + 2a(38\,818 + 18\,624)$$

$$= -340\,639 + 173\,535\,x + 77\,838\,a$$

Assume $a \sim 0$, then from $H_P - H_R = 0$ $\rightarrow$ $x = 1.742$

Subst.

$$\frac{a^2}{(13.1-a)(1.484-a)} = \frac{2.628\times10^{-5}}{4}, \quad \text{get} \quad a \approx 0.01125$$

Use this a in energy equation

$$x = \frac{302\,295 - 77\,838\times0.01125}{173\,535} = 1.737$$

$$\Rightarrow \quad \frac{a^2}{(13.062-a)(1.474-a)} = \frac{2.628\times10^{-5}}{4},\ a = 0.0112$$

$\Rightarrow$ $x = 1.737$ % excess air = **73.7 %**

$$\%\ NO = \frac{2\times0.0112\times100}{1+9.52\times1.737} = \mathbf{0.128\ \%}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

14.144E

Dry air is heated from 77 F to 7200 R in a 14.7 lbf/in.^{2} constant-pressure process. List the possible reactions that may take place and determine the equilibrium composition. Find the required heat transfer.

Air assumed to be 21% oxygen and 79% nitrogen by volume.

From the elementary reactions at 4000 K = 7200 R (A.11):

(1) $O_2 <=> 2\ O$ $\quad K_1 = 2.221 = y_O^2/y_{O2}$

(2) $N_2 <=> 2\ N$ $\quad K_2 = 3.141 \times 10^{-6} = y_N^2/y_{N2}$

(3) $N_2 + O_2 <=> 2\ NO$ $\quad K_3 = 0.08955 = y_{NO}^2/y_{N2}\, y_{O2}$

Call the shifts a,b,c respectively so we get

$n_{O2} = 0.21\text{-}a\text{-}c, \quad n_O = 2a, \quad n_{N2} = 0.79\text{-}b\text{-}c, \quad n_N = 2b,$

$n_{NO} = 2c, \quad n_{tot} = 1+a+b$

From which the molefractions are formed and substituted into the three equilibrium equations. The result is corrected for 1 atm = 14.7 lbf/in^2 = 101.325 kPa versus the tables 100 kPa

$$K_1 = 2.1511 = y_O^2/y_{O2} = 4a^2/[(1+a+b)(0.21-a-c)]$$

$$K_2 = 3.042\times10^{-6} = y_N^2/y_{N2} = 4b^2/[(1+a+b)(0.79-b-c)]$$

$$K_3 = 0.08955 = y_{NO}^2/y_{N2}\, y_{O2} = 4c^2/[(0.79-b-c)(0.21-a-c)]$$

which give 3 eqs. for the unknowns (a,b,c). Trial and error assume b = c = 0 solve for a from K_1 then for c from K_3 and finally given the (a,c) solve for b from K_2. The order chosen according to expected magnitude $K_1 > K_3 > K_2$

a = 0.15, b = 0.000832, c = 0.0244 =>

$n_{O2} = 0.0356, \quad n_O = 0.3, \quad n_{N2} = 0.765, \quad n_N = 0.00167, \quad n_{NO} = 0.049$

$$Q = H_{ex} - H_{in} = n_{O2}\Delta\bar{h}_{O2} + n_{N2}\Delta\bar{h}_{N2} + n_O(\bar{h}_{fO} + \Delta\bar{h}_O)$$

$$+ n_N(\bar{h}_{fN} + \Delta\bar{h}_N) + n_{NO}(\bar{h}_{fNO} + \Delta\bar{h}_{NO}) - 0$$

$$= 0.0356 \times 59\,632 + 0.765 \times 55\,902 + 0.3(107\,124 + 33\,394)$$

$$+ 0.00167(203\,216 + 33\,333) + 0.049(38\,818 + 57\,038)$$

= **92 135 Btu/lbmol air**

[If no reaction: $Q = n_{O2}\Delta\bar{h}_{O2} + n_{N2}\Delta\bar{h}_{N2}$ = 56 685 Btu/lbmol air]

In-Text Concept Questions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.a

Is stagnation temperature always higher than free stream temperature? Why?

Yes. Since kinetic energy can only be positive we have

$$h_0 = h_1 + \mathbf{V}_1^2/2 \; > \; h_1$$

If it is a gas with constant heat capacity we get

$$T_0 = T_1 + \mathbf{V}_1^2/2C_p$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.b

By looking at Eq. 15.25, rank the speed of sound for a solid, a liquid, and a gas.

Speed of sound: $\left(\frac{\partial P}{\partial \rho}\right)_s = c^2$

For a solid and liquid phase the density varies only slightly with temperature and constant s is also nearly constant T. We thus expect the derivative to be very high that is we need very large changes in P to give small changes in density.
A gas is highly compressible so the formula reduces to Eq.15.28 which gives modest values for the speed of sound.

15.c

Does speed of sound in an ideal gas depend on pressure? What about a real gas?

No. For an ideal gas the speed of sound is given by Eq.15.28

$$c = \sqrt{kRT}$$

and is only a function of temperature T.
For a real gas we do not recover the simple expression above and there is a dependency on P particularly in the dense gas region above the critical point.

15.d

Can a convergent adiabatic nozzle produce a supersonic flow?

No. From Eq.15.33 and a nozzle so $dP < 0$ it is required to have $dA > 0$ to reach $M > 1$. A convergent nozzle will have $M = 1$ at the exit, which is the smallest area. For lower back pressures there may be a shock standing outside the exit plane.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.e

To maximize the mass flow rate of air through a given nozzle, which properties should I try to change and in which direction, higher or lower?

The mass flow rate is given by Eq.15.41 and if we have $M = 1$ at the throat then Eq.15.42 gives the maximum mass flow rate possible.

Max flow for:

Higher upstream stagnation pressure
Lower upstream stagnation temperature

15.f

How do the stagnation temperature and pressure change in an isentropic flow?

The stagnation temperature and stagnation pressure are constant.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.g

Which of the cases in Fig. 15.17 (a-h) have entropy generation and which do not?

a. There is no flow so $s_{gen} = 0$.
b. Subsonic flow, reversible, so $s_{gen} = 0$.
c. Limit for subsonic flow, reversible, so $s_{gen} = 0$.
d. The only supersonic reversible flow solution, so $s_{gen} = 0$.
e. Supersonic reversible in nozzle $s_{gen} = 0$, irreversible outside.
f. Supersonic reversible in nozzle $s_{gen} = 0$, compression outside.
g. Shock stands at exit plane, $s_{gen} > 0$ across shock.
h. Shock is located inside nozzle, $s_{gen} > 0$ across shock.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.h

How does the stagnation temperature and pressure change in an adiabatic nozzle flow with an efficiency of less than 100%?

The stagnation temperature stays constant (energy eq.)
The stagnation pressure drops (s is generated, less kinetic energy).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.i

Table A.13 has a column for P_{oy}/P_{ox} why is there not one for T_{oy}/T_{ox}?

The stagnation pressure drops across the shock (irreversible flow) whereas the stagnation temperature is constant (energy equation).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.j

How high can a gas velocity (Mach number) be and still treat it as incompressible flow within 2% error?

The relative error in the ΔP versus kinetic energy, Eq.15.66, becomes

$$e = \frac{1}{4}\left(\frac{\mathbf{V}}{c_o}\right)^2 = 0.02 \quad \Rightarrow \quad M = \frac{\mathbf{V}}{c_o} = \sqrt{4 \times 0.02} = \mathbf{0.283}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Concept-Study Guide Problems

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.1

Which temperature does a thermometer or thermocouple measure? Would you ever need to make a correction to that?

Since the probe with the thermocouple in its tip is stationary relative to the moving fluid it will measure something close to the stagnation temperature. If that is high relative to the free stream temperature there will be significant heat transfer (convection and radiation) from the probe and it will measure a little less. For very high accuracy temperature measurements you must make some corrections for these effects.

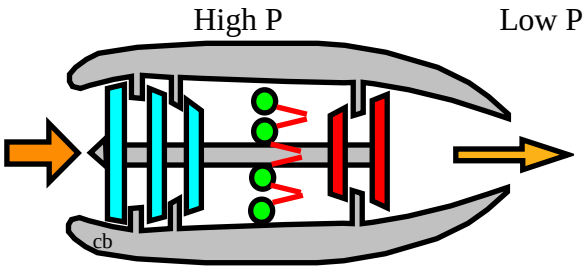
Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.2

The jet engine thrust is found from the overall momentum equation. Where is the actual force acting (it is not a long-range force in the flow)?

The compressor is generating the high pressure flow so the blades pushes hard on the flow and thus a force acts in the forward direction on the shaft holding the rotating blades. The high pressure in the chamber with combustion also has a net force in the forward direction as the flow leaves in the backwards direction so less wall area there and higher velocity. The pressure drop in the turbine means its blades pushes in the other direction but as the turbine exit pressure is higher than the ambient pressure the axial force is less than that of the compressor.

In front of the nozzle section there is a higher upstream pressure and a lower downstream pressure which is the pressure difference that generates the large exit velocity. This higher pressure plus the pressure difference across the turbine equals the pressure in the combustion chamber which is the compressor exit pressure. If the nozzle was not there this pressure would be lower and the pressure on all the surfaces including the compressor blades would provide less thrust.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.3

Most compressors have a small diffuser at the exit to reduce the high gas velocity near the rotating blades and increase the pressure in the exit flow. What does this do to the stagnation pressure?

For a reversible flow (ideal case) the stagnation pressure is constant. However, the reason it is done is to raise the pressure in a near reversible flow (diffuser) rather than let the flow reduce the peak velocities in a less reversible fashion which would lower the stagnation pressure.

15.4

A diffuser is a divergent nozzle used to reduce a flow velocity. Is there a limit for the Mach number for it to work like this?

Yes, the flow must be subsonic. If the flow was supersonic then increasing the flow area would increase the velocity.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

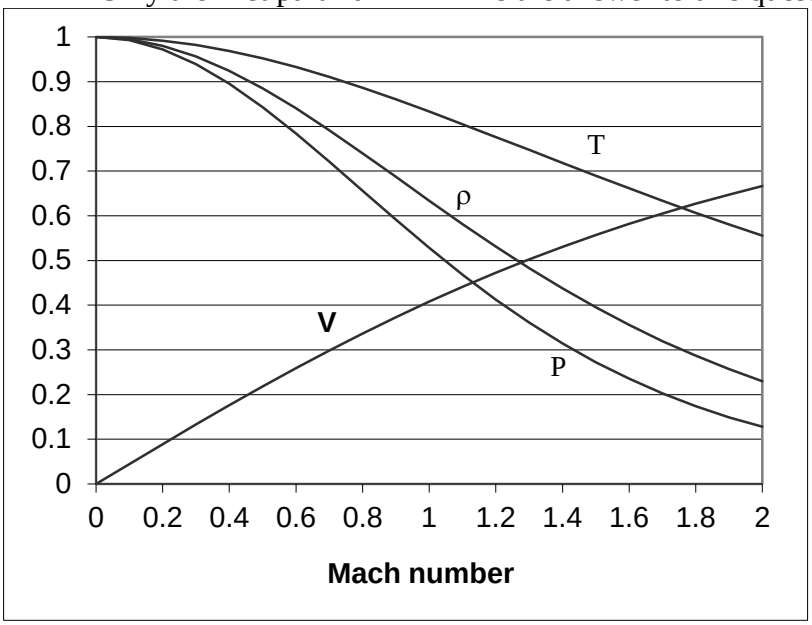
15.5

Sketch the variation in **V**, T, P, ρ and *M* for a subsonic flow into a convergent nozzle with *M* = 1 at the exit plane?

$$\mathbf{V} = M\,c = M\sqrt{kRT} = \sqrt{2C_p(T_o - T)}$$

Since we do not know the area versus length, we plot it versus mach number *M*. T, P and ρ relative to the stagnation state is listed in Table A.12 and given in eqs.15.34-36. A small spread sheet (M step 0.1) did the calculations.

Only the first part $0 < M < 1$ is the answer to this question.



The curves are plotted as the variables:

T / T_o

ρ / ρ_o

P / P_o

$V / \sqrt{2C_p\,T_o}$

and for k = 1.4

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

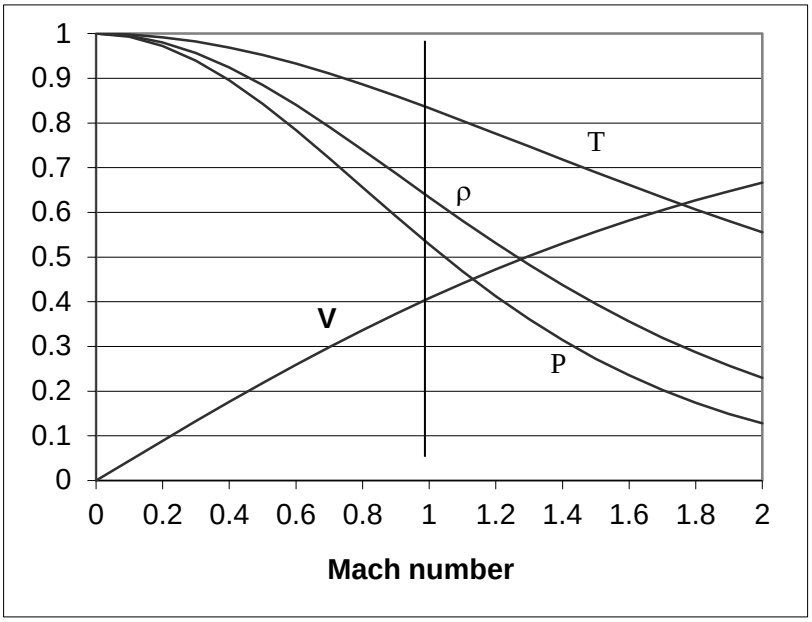
15.6

Sketch the variation in **V**, T, P, ρ and *M* for a sonic (*M* = 1) flow into a divergent nozzle with *M* = 2 at the exit plane?

$$\mathbf{V} = M\,c = M\sqrt{kRT} = \sqrt{2C_p(T_o - T)}$$

Since we do not know the area versus length, we plot it versus mach number *M*. T, P and ρ relative to the stagnation state is listed in Table A.12 and given in eqs.15.34-36.

Only the last part $1 < M < 2$ is the answer to this question.



The curves are plotted as the variables:

T / T_o

ρ / ρ_o

P / P_o

$V / \sqrt{2C_p T_o}$

and for k = 1.4

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.7

Can any low enough backup pressure generate an isentropic supersonic flow?

No. Only one back pressure corresponds to a supersonic flow, which is the exit pressure at state d in Figure 15.13. However a pressure lower than that can give an isentropic flow in the nozzle, case e, with a drop in pressure outside the nozzle. This is irreversible leading to an increase in s and therefore not isentropic.

15.8

Is there any benefit to operate a nozzle choked?

Yes. Since the mass flow rate is constant (max value) between points c and d in Fig. 15.12 a small variation in the back pressure will not have any influence. The nozzle then provides a constant mass flow rate free of surges up or down which is very useful for flow calibrations or other measurements where a constant mass flow rate is essential.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.9

Can a shock be located upstream from the throat?

No. The flow adjust so M = 1 at the throat.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.10

The high velocity exit flow in Example 15.7 is at 183 K. Can that flow be used to cool a room?

Being that cold it sounds like it could. However when the flow enters a room it eventually would have to slow down and then it has the stagnation temperature. If you let the flow run over a surface there will be a boundary layer with zero velocity at the surface and again there the temperature is close to the stagnation temperature.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.11

A convergent-divergent nozzle is presented for an application that requires a supersonic exit flow. What features of the nozzle do you look at first?

You look at the cross section area change through the nozzle. At the throat M = 1 so in the divergent section the velocity increases and the ratio A/A* determines how the flow changes. The exit area can then tell you what the exit mach number will be and if you can have a reversible flow or not.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.12

To increase the flow through a choked nozzle, the flow can be heated/cooled or compressed/expanded (four processes) before or after the nozzle. Explain which of these eight possibilities will help and which will not.

The mass flow rate through a choked nozzle is given by Eq.15.42. Since k and R are constant it varies with the upstream stagnation properties P_o and T_o.

After nozzle: Any downstream changes have **no effects**.
Before nozzle: Upstream changes in P_o and T_o has an influence.

a. Heat This lowers mass flow rate (T_o increases)
b. Cool This raises mass flow rate (T_o decreases)
c. Compress. Raises P_o and T_o opposite effects.

Isentropic: $P_{o\,new} = P_o\, r_p$ and $T_{o\,new} = T_o \left(r_p\right)^{\frac{k-1}{k}}$

$$P_{o\,new} / \sqrt{T_{o\,new}} = \left(r_p\right)^{\frac{k+1}{2k}} \left[P_o / \sqrt{T_o}\right] > \left[P_o / \sqrt{T_o}\right]$$

So the mass flow rate increases

d. Expand. Lowers P_o and T_o opposite effects. Assume isentropic, then mass flow rate decreases.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.13

Suppose a convergent-divergent nozzle is operated as case h in Fig. 15.17. What kind of nozzle could have the same exit pressure but with a reversible flow?

A convergent nozzle, having subsonic flow everywhere assuming the pressure ratio is higher than the critical.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Stagnation Properties

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.14

A stationary thermometer measures 80°C in an air flow that has a velocity of 200 m/s. What is the actual flow temperature?

We assume that the thermometer measures the stagnation temperature, that is the probe (bulb, thermistor or thermo-couple junction sits stationary).

$$h_0 = h_1 + \mathbf{V}_1^2/2 \qquad \Rightarrow \qquad T_1 = T_0 - \mathbf{V}_1^2/2C_p$$

$$T_1 = 80^{o}\text{C} - \frac{200^2}{2000 \times 1.004}\frac{(\text{m/s})^2}{\text{J/kg-K}} = \mathbf{60^{o}C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.15

Steam leaves a nozzle with a pressure of 500 kPa, a temperature of 350°C, and a velocity of 250 m/s. What is the isentropic stagnation pressure and temperature?

Stagnation enthalpy from energy equation and values from steam tables B.1.3

$$h_0 = h_1 + \mathbf{V}_1^2/2 = 3167.7 \text{ kJ/kg} + \frac{250^2}{2000}\frac{(\text{m/s})^2}{\text{J/kJ}} = 3198.4 \text{ kJ/kg}$$

$$s_0 = s_1 = 7.6329 \text{ kJ/kg K}$$

It can be linearly interpolated from the printed tables

Computer software: $(h_o, s_o) \Rightarrow T_o = \mathbf{365°C}$, $P_o = \mathbf{556 \text{ kPa}}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.16

Steam at 1600 kPa, 300^{o}C flows so it has a stagnation (total) pressure of 1800 kPa. Find the velocity and the stagnation temperature.

The stagnation state has the same entropy as the inlet state so:

1: 1600 kPa, 300^{o}C has h = 3034.83 kJ/kg, s = 6.8844 kJ/kg-K
Stagnation: 1800 kPa, s_0 = 6.8844 kJ/kg-K has

Table B.1.3: T_{01} = **316.5^{o}C**, h_{01} = 3066.155 kJ/kg

$$\mathbf{V}_1^2/2 = h_{01} - h_1 = 3066.155 - 3034.83 = 31.325 \text{ kJ/kg}$$

$$\mathbf{V}_1 = \sqrt{2 \times (h_{o1} - h_1)} = \sqrt{2 \times 31.325 \times 1000 \text{ J/kg}} = \mathbf{250.3 \text{ m/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.17

An object from space enters the earth's upper atmosphere at 5 kPa, 100 K, with a relative velocity of 2500 m/s or more . Estimate the object`s surface temperature.

$h_{o1} - h_1 = \mathbf{V}_1^2/2 = 2500^2/2000 = 3125$ kJ/kg

$h_{o1} = h_1 + 2000 = 100 + 3125 = 3225$ kJ/kg => T = **2767 K**

The value for h_1 from ideal gas table A.7 was estimated since the lowest T in the table is 200 K.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.18

The products of combustion of a jet engine leave the engine with a velocity relative to the plane of 500 m/s, a temperature of 525°C, and a pressure of 75 kPa. Assuming that $k = 1.32$, $C_p = 1.15$ kJ/kg K for the products, determine the stagnation pressure and temperature of the products relative to the airplane.

Energy Eq.: $h_{o1} - h_1 = \mathbf{V}_1^2/2 = 500^2/2000 = 125$ kJ/kg

$T_{o1} - T_1 = (h_{o1} - h_1)/C_p = 125/1.15 = 108.7$ K

$T_{o1} = 525 + 273.15 + 108.7 =$ **906.8 K**

Isentropic process relates to the stagnation pressure

$P_{o1} = P_1(T_{o1}/T_1)^{k/(k-1)} = 75(906.8/798.15)^{4.125} =$ **127 kPa**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.19

Steam is flowing to a nozzle with a pressure of 400 kPa. The stagnation pressure and temperature are measured to be 600 kPa and 350^{o}C, respectively. What are the flow velocity and temperature?

Stagnation state Table B.1.3: $h_{o1} = 3165.66$ kJ/kg, $s_{o1} = 7.5463$ kJ/kg K

State 1: 400 kPa, $s_1 = s_{o1} = 7.5463$ kJ/kg K

$$T_1 = 250 + (300 - 250)\frac{7.5463 - 7.3788}{7.5661 - 7.3788} = \mathbf{294.7^{o}C}$$

$$h_1 = 2964.16 + \frac{7.5463 - 7.3788}{7.5661 - 7.3788}(3066.75 - 2964.16) = 3055.9 \text{ kJ/kg}$$

Energy equation gives

$$\mathbf{V}_1^2/2 = h_{o1} - h_1 = 3165.66 - 3055.9 = 109.76 \text{ kJ/kg}$$

$$\mathbf{V}_1 = \sqrt{2 \times (h_{o1} - h_1)} = \sqrt{(2 \times 109.76 \times 1000) \text{ J/kg}} = \mathbf{468.5 \text{ m/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.20

A meteorite melts and burn up at temperatures of 3000 K. If it hits air at 5 kPa, 50 K how high a velocity should it have to experience such a temperature?

Assume we have a stagnation T = 3000 K

$h_1 + \mathbf{V}_1^2/2 = h_{stagn.}$

Use table A.7, $h_{stagn.}$ = 3525.36 kJ/kg, h_1 = 50 kJ/kg

$\mathbf{V}_1^2/2$ = 3525.36 – 50 = 3475.4 kJ/kg (remember convert to J/kg = m^2/s^2)

$\mathbf{V}_1 = \sqrt{2 \times 3475.4 \times 1000 \text{ J/kg}}$ = **2636 m/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.21

Air leaves a compressor in a pipe with a stagnation temperature and pressure of 150°C, 300 kPa, and a velocity of 125 m/s. The pipe has a cross-sectional area of 0.02 m^2. Determine the static temperature and pressure and the mass flow rate.

$h_{o1} - h_1 = \mathbf{V}_1^2/2 = 125^2/2000 = 7.8125$ kJ/kg

$T_{o1} - T_1 = (h_{o1} - h_1)/C_p = 7.8125/1.004 = 7.8$ K

$T_1 = T_{o1} - \Delta T = 150 - 7.8 =$ **142.2 °C = 415.4 K**

$P_1 = P_{o1}(T_1/T_{o1})^{k/(k-1)} = 300$ kPa $(415.4/423.15)^{3.5} =$ **281 kPa**

$$\dot{m} = \rho A\mathbf{V} = \frac{A\mathbf{V}}{v} = \frac{P_1 A \mathbf{V}_1}{RT_1} = \frac{281.2(0.02)(125)}{0.287(415.4)} = \textbf{5.9 kg/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.22

I drive down the highway at 110 km/h on a day with 25°C, 101.3 kPa. I put my hand, cross sectional area 0.01 m^2, flat out the window. What is the force on my hand and what temperature do I feel?

The air stagnates on the hand surface : $h_1 + \mathbf{V}_1^2/2 = h_{stagn.}$

Use constant heat capacity

$$T_{stagn.} = T_1 + \frac{\mathbf{V}_1^2/2}{C_p} = 25 + \frac{0.5 \times 110^2 \times (1000/3600)^2}{1004} = \mathbf{25.465°C}$$

Assume a reversible adiabatic compression

$$P_{stagn.} = P_1 (T_{stagn.}/T_1)^{k/(k-1)} = 101.3 \text{ kPa } (298.615/298.15)^{3.5}$$

$$= \mathbf{101.85 \text{ kPa}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.23

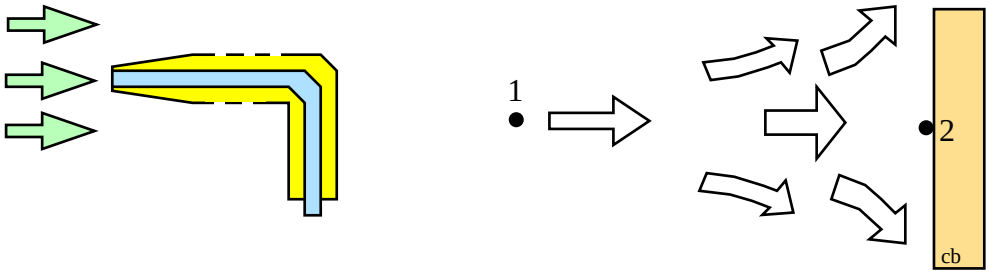
A stagnation pressure of 110 kPa is measured for an airflow where the pressure is 100 kPa and 20°C in the approach flow. What is the incomming velocity?

Assume a reversible adiabatic compression

$$T_{o1} = T_1 \times (P_{o1}/P_1)^{(k-1)/k} = 293.15 \text{ K} \times \left(\frac{110}{100}\right)^{0.2857} = 301.24 \text{ K}$$

$$\mathbf{V}_1^2/2 = h_{o1} - h_1 = C_p (T_{o1} - T_1) = 1.004 (301.24 - 293.15) = 8.1246 \text{ kJ/kg}$$

$$\mathbf{V}_1 = \sqrt{2 \times 8.1246 \times 1000} = \mathbf{127.5 \text{ m/s}}$$



To the left a Pitot tube, blue inner tube measures stagnation pressure and yellow outer tube with holes in it measures static pressure. To the right is a stagnation point on a wall relative to the free stream flow at state 1.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.24

A 4-cm inner diameter pipe has an inlet flow of 10 kg/s water at 20°C, 200 kPa. After a 90 degree bend as shown in Fig. P15.24, the exit flow is at 20°C, 190 kPa. Neglect gravitational effects and find the anchoring forces F_x and F_y.

$$D = 0.04 \text{ m} \quad \Rightarrow \quad A = \frac{\pi}{4} D^2 = 0.001257 \text{ m}^2$$

$$\mathbf{V}_{avg} = \frac{\dot{m}}{\rho A} = \frac{10 \times 0.001002}{0.001257} = 7.971 \text{ m/s}$$

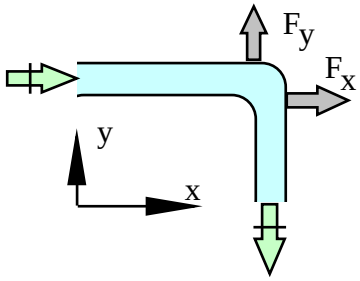
Now we can do the x and y direction momentum equations for steady flow and the same magnitude of the velocity, but different directions

X-dir: $\quad 0 = \dot{m}\, \mathbf{V}_{avg\ 1} + F_x - \dot{m} \times 0 + (P_1 - P_o)\, A$

Y-dir: $\quad 0 = \dot{m} \times 0 + F_y - \dot{m} \times (-\mathbf{V}_{avg\ 2}) + (P_2 - P_o)\, A$

$$F_x = -\dot{m}\, \mathbf{V}_{avg\ 1} - (P_1 - P_o)\, A$$
$$= -10 \times 7.97 - 100 \times 0.001257 \times 1000 = \mathbf{-205\ N}$$

$$F_y = -\dot{m}\, \mathbf{V}_{avg\ 2} - (P_2 - P_o)\, A$$
$$= -10 \times 7.97 - 90 \times 0.001257 \times 1000 = \mathbf{-193\ N}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.25

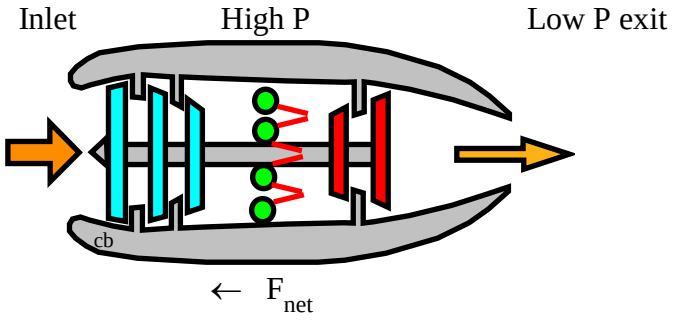
A jet engine receives a flow of 150 m/s air at 75 kPa, 5°C across an area of 0.6 m^2 with an exit flow at 450 m/s, 75 kPa, 800 K. Find the mass flow rate and thrust.

$\dot{m} = \rho A\mathbf{V}$; ideal gas $\rho = P/RT$

$$\dot{m} = (P/RT)A\mathbf{V} = \left(\frac{75}{0.287 \times 278.15}\right) \times 0.6 \times 150 = 0.9395 \times 0.6 \times 150$$

$$= \mathbf{84.555\ kg/s}$$

$$F_{net} = \dot{m}\,(\mathbf{V}_{ex} - \mathbf{V}_{in}) = 84.555 \times (450 - 150) = \mathbf{25\ 367\ N}$$



The shaft must have axial load bearings to transmit thrust to aircraft.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.26

How large a force must be applied to a squirt gun to have 0.1 kg/s water flow out at 20 m/s? What pressure inside the chamber is needed?

$$F = \frac{d\, m\mathbf{V}}{dt} = \dot{m}\,\mathbf{V} = 0.1 \times 20 \ \text{kg m/s}^2 = \mathbf{2\ N}$$

Eq.15.21: $v\Delta P = 0.5\,\mathbf{V}^2$

$$\Delta P = 0.5\,\mathbf{V}^2/v = 0.5 \times 20^2 / 0.001$$
$$= 200\,000\ \text{Pa} = \mathbf{200\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.27

A jet engine at takeoff has air at 20°C, 100 kPa coming at 25 m/s through the 1.0 m diameter inlet. The exit flow is at 1200 K, 100 kPa, through the exit nozzle of 0.4 m diameter. Neglect the fuel flow rate and find the net force (thrust) on the engine.

$$A_1 = \frac{\pi}{4} D^2 = 0.7854 \text{ m}^2; \qquad A_2 = \frac{\pi}{4} D^2 = 0.1257 \text{ m}^2$$

$$v_1 = \frac{RT}{P} = \frac{0.287 \times 293.15}{100} = 0.8409 \text{ m}^3/\text{kg}; \quad v_2 = 3.444 \text{ m}^3/\text{kg}$$

$$\dot{m} = A\mathbf{V}/v = A_1\mathbf{V}_1/v_1 = \frac{0.7854 \times 25}{0.8409} = 48.0 \text{ kg/s}$$

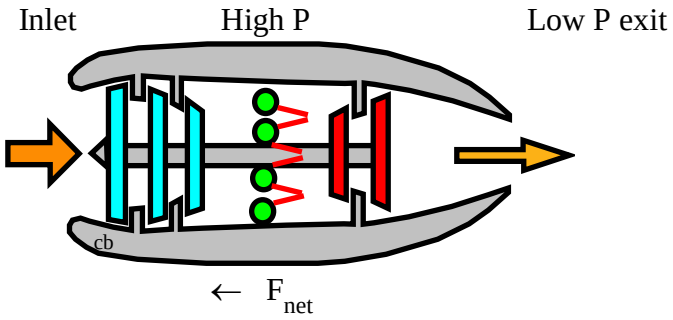
$$\mathbf{V}_2 = \frac{\dot{m} v_2}{A_2} = \frac{48.0 \times 3.444}{0.1257} = 1315 \text{ m/s}$$

Now we can do the x direction momentum equation for steady flow and the same mass flow rate in and out

$$\text{X-dir:} \qquad 0 = \dot{m}\,\mathbf{V}_1 + F_x + (P_1 - P_o)\,A_1 - \dot{m}\,\mathbf{V}_2 - (P_2 - P_o)\,A_2$$

$$F_x = -\dot{m}\,\mathbf{V}_1 - (P_1 - P_o)\,A_1 + \dot{m}\,\mathbf{V}_2 + (P_2 - P_o)\,A_2$$

$$= \dot{m}\,(\mathbf{V}_2 - \mathbf{V}_1) - 0 + 0 = 48\,(1315 - 25) = \mathbf{61\ 920\ N}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.28

A water turbine using nozzles is located at the bottom of Hoover Dam 175 m below the surface of Lake Mead. The water enters the nozzles at a stagnation pressure corresponding to the column of water above it minus 20% due to losses. The temperature is 15°C and the water leaves at standard atmospheric pressure. If the flow through the nozzle is reversible and adiabatic, determine the velocity and kinetic energy per kilogram of water leaving the nozzle.

The static pressure at the 175 m depth is:

$$\Delta P = \rho g \Delta Z = \frac{g\Delta Z}{v} = \frac{9.807 \times 175}{0.001001 \times 1000} = 1714.5 \text{ kPa}$$

$$\Delta P_{ac} = 0.8\ \Delta P = 1371.6 \text{ kPa}$$

Use Bernoulli's equation: $v\Delta P = \mathbf{V}_{ex}^2/2$

$$\Rightarrow \mathbf{V}_{ex} = \sqrt{2v\Delta P}$$

$$\mathbf{V}_{ex} = \sqrt{2 \times 0.001001 \times 1000 \times 1371.6} = \mathbf{62.4\ m/s}$$

$$\mathbf{V}_{ex}^2/2 = v\Delta P = \mathbf{1.373\ kJ/kg}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.29

A water cannon sprays 1 kg/s liquid water at a velocity of 100 m/s horizontally out from a nozzle. It is driven by a pump that receives the water from a tank at 15°C, 100 kPa. Neglect elevation differences and the kinetic energy of the water flow in the pump and hose to the nozzle. Find the nozzle exit area, the required pressure out of the pump and the horizontal force needed to hold the cannon.

$$\dot{m} = \rho A \mathbf{V} = A\mathbf{V}/v \Rightarrow A = \dot{m}v/\mathbf{V} = 1 \frac{0.001001}{100} = \mathbf{1.0 \times 10^{-5}\ m^2}$$

$$\dot{W}_p = \dot{m} w_p = \dot{m} v (P_{ex} - P_{in}) = \dot{m} \mathbf{V}_{ex}^2 / 2$$

$$P_{ex} = P_{in} + \mathbf{V}_{ex}^2 / 2v = 100 + 100^2/2 \times 1000 \times 0.001 = \mathbf{150\ kPa}$$

$$F = \dot{m} \mathbf{V}_{ex} = 1 \times 100 = \mathbf{100\ N}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.30

An irrigation pump takes water from a lake and discharges it through a nozzle as shown in Fig. P15.30. At the pump exit the pressure is 900 kPa, and the temperature is 20°C. The nozzle is located 15 m above the pump and the atmospheric pressure is 100 kPa. Assuming reversible flow through the system determine the velocity of the water leaving the nozzle.

Assume we can neglect kinetic energy in the pipe in and out of the pump. Incompressible flow so Bernoulli's equation applies ($\mathbf{V}_1 \cong \mathbf{V}_2 \cong \mathbf{V}_3 \cong 0$)

Bernoulli: $v(P_3 - P_{2)} + (\mathbf{V}_3^2 - \mathbf{V}_2^2)/2 + g(Z_3 - Z_{2)} = 0$

$$P_3 = P_2 - \frac{g(Z_3 - Z_2)}{v} = 900 - \frac{9.807 \times 15}{1000 \times 0.001002} = 753 \text{ kPa}$$

Bernoulli: $\mathbf{V}_4^2/2 = v(P_3 - P_4)$

$$\Rightarrow \mathbf{V}_4 = \sqrt{2v(P_3 - P_4)} = \sqrt{2 \times 0.001002 \times 653 \times 1000} = \mathbf{36.2\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.31

A water tower on a farm holds 1 m^3 liquid water at 20°C, 100 kPa in a tank on top of a 5 m tall tower. A pipe leads to the ground level with a tap that can open a 1.5 cm diameter hole. Neglect friction and pipe losses, and estimate the time it will take to empty the tank for water.

Incompressible flow so we can use Bernoulli Equation.

$$P_e = P_i; \quad \mathbf{V}_i = 0; \quad Z_e = 0; \quad Z_i = H$$

$$\mathbf{V}_e^2/2 = gZ_i \quad \Rightarrow \quad \mathbf{V}_e = \sqrt{2gZ} = \sqrt{2 \times 9.807 \times 5} = 9.9 \text{ m/s}$$

$$\dot{m} = \rho A \mathbf{V}_e = A\mathbf{V}_e/v = \Delta m/\Delta t$$

$$\Delta m = V/v; \quad A = \pi D^2/4 = \pi \times 0.015^2 / 4 = 1.77 \times 10^{-4} \text{ m}^2$$

$$\Rightarrow \quad \Delta t = \Delta m v/A\mathbf{V}_e = V/A\mathbf{V}_e$$

$$\Delta t = \frac{1}{1.77 \times 10^{-4} \times 9.9} = \mathbf{571.6 \text{ sec}} = \mathbf{9.53 \text{ min}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.32

Find the speed of sound for air at 100 kPa at the two temperatures 0°C and 30°C. Repeat the answer for carbon dioxide and argon gases.

From eq. 15.28 we have

$$c_0 = \sqrt{kRT} = \sqrt{1.4 \times 0.287 \times 273.15 \times 1000} = \mathbf{331\ m/s}$$

$$c_{30} = \sqrt{1.4 \times 0.287 \times 303.15 \times 1000} = \mathbf{349\ m/s}$$

For Carbon Dioxide: R = 0.1889 kJ/kg K, k = 1.289

$$c_0 = \sqrt{1.289 \times 0.1889 \times 273.15 \times 1000} = \mathbf{257.9\ m/s}$$

$$c_{30} = \sqrt{1.289 \times 0.1889 \times 303.15 \times 1000} = \mathbf{271.7\ m/s}$$

For Argon: R = 0.2081 kJ/kg K, k = 1.667

$$c_0 = \sqrt{1.667 \times 0.2081 \times 273.15 \times 1000} = \mathbf{307.8\ m/s}$$

$$c_{30} = \sqrt{1.667 \times 0.2081 \times 303.15 \times 1000} = \mathbf{324.3\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.33

Find the expression for the anchoring force R_x for an incompressible flow like in Figure 15.6. Show that it can be written as

$$R_x = \frac{\mathbf{V}_i - \mathbf{V}_e}{\mathbf{V}_i + \mathbf{V}_e}\left[(P_i - P_o)A_i + (P_e - P_o)A_e\right]$$

Apply the X-dir momentum equation for a steady flow

$$0 = R_x + (P_i - P_o)A_i - (P_e - P_o)A_e + \dot{m}\mathbf{V}_i - \dot{m}\mathbf{V}_e$$

Bernoulli equation for the flow is

$$0.5(\mathbf{V}_e^{\,2} - \mathbf{V}_i^{\,2}) + v\,(P_e - P_i) = 0 \qquad \Rightarrow \qquad \mathbf{V}_e - \mathbf{V}_i = \frac{2v\,(P_i - P_e)}{\mathbf{V}_i + \mathbf{V}_e}$$

Continuity equation gives

$$\dot{m} = A_i\mathbf{V}_i\,/v = A_e\mathbf{V}_e\,/v$$

Solve for R_x from the momentum equation

$$R_x = \dot{m}\,(\mathbf{V}_e - \mathbf{V}_i) + (P_e - P_o)A_e - (P_i - P_o)A_i$$

$$= \frac{A_i\mathbf{V}_i}{v}\frac{2v\,(P_i - P_e)}{\mathbf{V}_i + \mathbf{V}_e} + (P_e - P_o)A_e - (P_i - P_o)A_i$$

Multiply in and use continuity equation for second term

$$R_x = \frac{2}{\mathbf{V}_i + \mathbf{V}_e}\left[P_iA_i\mathbf{V}_i - P_eA_e\mathbf{V}_e\right] + (P_e - P_o)A_e - (P_i - P_o)A_i$$

$$= \frac{2}{\mathbf{V}_i + \mathbf{V}_e}\left[P_iA_i\mathbf{V}_i - P_eA_e\mathbf{V}_e + \tfrac{1}{2}(P_e - P_o)A_e\mathbf{V}_e - \tfrac{1}{2}(P_i - P_o)A_i\mathbf{V}_i\right.$$

$$\left. + \tfrac{1}{2}(P_e - P_o)A_e\mathbf{V}_i - \tfrac{1}{2}(P_i - P_o)A_i\mathbf{V}_e\right]$$

Now put the first four terms together

$$R_x = \frac{2}{\mathbf{V}_i + \mathbf{V}_e}\left[\tfrac{1}{2}(P_i - P_o)A_i\mathbf{V}_i - \tfrac{1}{2}(P_e - P_o)A_e\mathbf{V}_e\right.$$

$$\left. + \tfrac{1}{2}(P_e - P_o)A_e\mathbf{V}_i - \tfrac{1}{2}(P_i - P_o)A_i\mathbf{V}_e\right]$$

$$= \frac{2}{\mathbf{V}_i + \mathbf{V}_e}\left[\tfrac{1}{2}(P_i - P_o)A_i(\mathbf{V}_i - \mathbf{V}_e) + \tfrac{1}{2}(P_e - P_o)A_e(\mathbf{V}_i - \mathbf{V}_e)\right]$$

$$= \frac{\mathbf{V}_i - \mathbf{V}_e}{\mathbf{V}_i + \mathbf{V}_e}\left[(P_i - P_o)A_i + (P_e - P_o)A_e\right]$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.34

Estimate the speed of sound for steam directly from Eq. 15.25 and the steam tables for a state of 6 MPa, 400°C. Use table values at 5 and 7 MPa at the same entropy as the wanted state. Eq. 15.25 is then done by finite difference. Find also the answer for the speed of sound assuming steam is an ideal gas.

Eq.15.25: $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = \left(\frac{\Delta P}{\Delta \rho}\right)_s$

State 6 MPa, 400°C $\Rightarrow$ s = 6.5407 kJ/kg K

7 MPa, s $\Rightarrow$ v = 0.04205 m^3/kg; $\rho = 1/v = 23.777$ kg/m^3

5 MPa, s $\Rightarrow$ v = 0.05467 m^3/kg; $\rho = 1/v = 18.2909$ kg/m^3

$$c^2 = \frac{7000 - 5000}{23.777 - 18.2909} = 364.56 \times 1000 \quad \Rightarrow \quad c = \mathbf{603.8\ m/s}$$

From Table A.8: $C_p = \frac{1338.56 - 1235.3}{50} = 2.0652$ kJ/kg K

$C_v = C_p - R = 2.0652 - 0.4615 = 1.6037$ kJ/kg K

$k = C_p/C_v = 1.288$; R = 0.4615 kJ/kg K (from A.5)

Now do the speed of sound from Eq.15.28

$c = \sqrt{kRT} = \sqrt{1.288 \times 0.4615 \times 673.15 \times 1000} =$ **632.6 m/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.35

Use the CATT3 software to solve the previous problem.

From Eq. 15.25: $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s$

Superheated vapor water at 400°C, 6000 kPa

CATT3: $v = 0.04739$ m^3/kg, $s = 6.541$ kJ/kg K

At P = 6200 kPa & s = 6.541 kJ/kg K: T = 405.1°C, v = 0.0462 m^3/kg

At P = 5800 kPa & s = 6.541 kJ/kg K: T = 394.8°C, v = 0.04866 m^3/kg

$$c^2 = -(0.04739)^2 \left(\frac{6.2 - 5.8}{0.0462 - 0.04866}\right) \frac{MJ}{kg} = 0.36517 \times 10^6 \text{ m}^2/\text{s}^2$$

$$\Rightarrow \quad c = \mathbf{604 \text{ m/s}}$$

From Table A.8: $C_p = \frac{1338.56 - 1235.3}{50} = 2.0652$ kJ/kg K

$C_v = C_p - R = 2.0652 - 0.4615 = 1.6037$ kJ/kg K

$k = C_p/C_v = 1.288$; R = 0.4615 kJ/kg K (from A.5)

Now do the speed of sound from Eq.15.28

$$c = \sqrt{kRT} = \sqrt{1.288 \times 0.4615 \times 673.15 \times 1000} = \mathbf{632.6 \text{ m/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

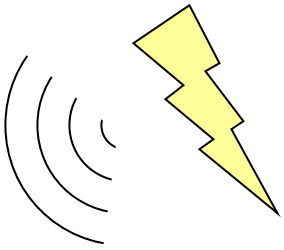
15.36

If the sound of thunder is heard 5 seconds after the lightning is seen and the weather is 20°C. How far away is the lightning taking place?

The sound travels with the speed of sound in air (ideal gas). Use the formula in Eq.15.28

$$L = c \times t = \sqrt{kRT} \times t = \sqrt{1.4 \times 0.287 \times 293.15 \times 1000} \times 5 = \mathbf{1716\ m}$$

For every 3 seconds after the lightning the sound travels about 1 km.



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.37

Find the speed of sound for carbon dioxide at 2500 kPa, 60°C using either the tables or the CATT3 software (same procedure as in Problem 15.34) and compare that with Eq.15.28.

From Eq. 15.25: $c^2 = \left(\frac{\partial P}{\partial \rho}\right)_s = -v^2\left(\frac{\partial P}{\partial v}\right)_s$

Superheated carbon dioxide at 60°C, 2500 kPa

CATT3: $v = 0.02291$ m^3/kg, $s = 1.521$ kJ/kg K

At P = 2600 kPa & $s = 1.521$ kJ/kg K: $T = 63.02$°C, $v = 0.02221$ m^3/kg

At P = 2400 kPa & $s = 1.521$ kJ/kg K: $T = 56.9$°C, $v = 0.02365$ m^3/kg

$$c^2 = -(0.02291)^2 \left(\frac{2.6 - 2.4}{0.02221 - 0.02365}\right) \frac{\text{MJ}}{\text{kg}} = 7.8983 \times 10^4 \text{ m}^2/\text{s}^2$$

$$\Rightarrow \quad c = \mathbf{270 \text{ m/s}}$$

From Table A.5: $k = C_p/C_v = 1.289$; $R = 0.1889$ kJ/kg K

Now do the speed of sound from Eq.15.28

$$c = \sqrt{kRT} = \sqrt{1.289 \times 0.1889 \times 333.15 \times 1000} = \mathbf{284.8 \text{ m/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.38

A jet flies at an altitude of 12 km where the air is at -40^{o}C, 45 kPa with a velocity of 1000 km/h. Find the Mach number and the stagnation temperature on the nose.

From Table A.5: $k = C_p/C_v = 1.4$; $R = 0.287$ kJ/kg K

Now do the speed of sound from Eq.15.28

$$c = \sqrt{kRT} = \sqrt{1.4 \times 0.287 \times 233.15 \times 1000} = 306 \text{ m/s}$$

$\mathbf{V}$ = 1000 km/h = 1000 (km/h) × 1000 (m/km) /3600 (s/h)= 278 m/s

$M = \mathbf{V} / c = 278/306 =$ **0.908**

$$h_0 = h_1 + \mathbf{V}_1^2/2 \quad \Rightarrow \quad T_0 = T_1 + \mathbf{V}_1^2 / 2C_p = -40 + \frac{278^2}{2 \times 1004} = \mathbf{-1.5^{o}C}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.39

The speed of sound in liquid water at 25°C is about 1500 m/s. Find the stagnation pressure and temperature for a M = 0.1 flow at 25°C, 100 kPa. Is it possible to get a significant mach number flow of liquid water?

$$\mathbf{V} = M\,c = 0.1 \times 1500 = 150 \text{ m/s}$$

$$h_0 = h_1 + \mathbf{V}_1^2/2$$

Bernoulli Eq.: $$\Delta P = \mathbf{V}_1^2/2v = \frac{150^2}{2 \times 0.001} = 11.25 \times 10^6 \text{ Pa} = 11.25 \text{ MPa}$$

$$P_0 = P_1 + \Delta P = 100 + 11\,250 = \mathbf{11\,350\ kPa}$$

$$T_0 = T_1 + \mathbf{V}_1^2 / 2C_p = 25 + \frac{150^2}{2 \times 4180} = \mathbf{27.7^oC}$$

Remark: Notice the very high pressure. To get a higher velocity you need a higher pressure to accelerate the fluid, that is not feasible for any large flow rate.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.40

Steam flowing at 15 m/s 1800 kPa, 300°C expands to 1600 kPa in a converging nozzle. Find the exit velocity and area ratio A_e / A_i.

Solve the problem with the steam tables.
Inlet state: $v_i = 0.14021$ m^3/kg, $h_i = 3029.21$ kJ/kg, $s_i = 6.8226$ kJ/kg-K
Exit state: $(P_e, s_e = s_i)$ $v_e = 0.15371$ m^3/kg, $h_e = 3000.995$ kJ/kg

Energy Eq.: $\mathbf{V}_i^2 / 2 + h_i = \mathbf{V}_e^2 / 2 + h_e$; $\mathbf{V}_e^2 = \mathbf{V}_i^2 + 2(h_i - h_e)$

$$\mathbf{V}_e = \sqrt{15 \times 15 + 2000(3029.21 - 3000.995)} = \mathbf{238\ m/s}$$

Same mass flow rate so

$$A_e/A_i = (v_e/v_i)(V_i/V_e) = \frac{0.15371}{0.14021} \times \frac{15}{238} = \mathbf{0.06909}$$

If we solved as ideal gas with constant specific heat we get (k = 1.327)

$$T_e = T_i\,(P_e/P_i)^{(k-1)/k} = 573.15\,(1600/1800)^{0.2464} = 556.76\ \text{K}$$

$$\mathbf{V}_e = \sqrt{\mathbf{V}_i^2 + 2C_p(T_i - T_e)} = \sqrt{15 \times 15 + 2 \times 1872(573.15 - 556.76)}$$
$$= \mathbf{248\ m/s}$$

$$A_e/A_i = (v_e/v_i)(V_i/V_e) = (P_i/P_e)^{1/k}(V_i/V_e) = \left(\frac{1800}{1600}\right)^{0.7536} \times \frac{15}{248} = \mathbf{0.0661}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.41

A convergent nozzle has a minimum area of 0.1 m^2 and receives air at 175 kPa, 1000 K flowing with 100 m/s. What is the back pressure that will produce the maximum flow rate and find that flow rate?

$$\frac{P^*}{P_o} = \left(\frac{2}{k+1}\right)^{\frac{k}{k-1}} = 0.528 \qquad \text{Critical Pressure Ratio}$$

Find P_o:

$$h_0 = h_1 + \mathbf{V}_1^2/2 = 1046.22 + 100^2/2000 = 1051.22 \text{ kJ/kg}$$

$$T_0 = T_i + 4.4 = 1004.4 \text{ K} \quad \text{from table A.7}$$

$$P_0 = P_i \, (T_0/T_i)^{k/(k-1)} = 175 \times \quad (1004.4/1000)^{3.5} = 177.71 \text{ kPa}$$

The mass flow rate comes from the throat properties

$$P^* = 0.528 \, P_o = 0.528 \times 177.71 = \mathbf{93.83 \text{ kPa}}$$

$$T^* = 0.8333 \, T_o = 836.97 \text{ K}$$

$$\rho^* = \frac{P^*}{RT^*} = \frac{93.83}{0.287 \times 836.97} = 0.3906 \text{ kg/m}^3$$

$$\mathbf{V} = c = \sqrt{kRT^*} = \sqrt{1.4 \times 1000 \times 0.287 \times 836.97} = \mathbf{579.9 \text{ m/s}}$$

$$\dot{m} = \rho A \mathbf{V} = 0.3906 \times 0.1 \times 579.9 = \mathbf{22.65 \text{ kg/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.42

A convergent-divergent nozzle has a throat area of 100 mm^2 and an exit area of 175 mm^2. The inlet flow is helium at a stagnation pressure of 1 MPa, stagnation temperature of 375 K. What is the back pressure that will give sonic condition at the throat, but subsonic everywhere else?

For this flow we have helium with $k_{He} = 1.667$, so we cannot use the tables for air. We need the solution to the curve labeled c in Fig. 15.13. For critical flow at the throat we have from Table 15.1 last column

$$P^* = 0.4867\ P_o = 486.7\ \text{kPa}$$

Now we need to find the conditions where the area ratio is

$$A_E/A^* = 175/100 = 1.75$$

that is solve for M in Eq. 15.43 given the area ratio. This is nonlinear so we have to iterate on it. Here (k+1)/2(k-1) = 2 so look also at Fig. 15.10 for the general shape.

$$M = 0.4 \Rightarrow A/A^* = (1/0.4)\ [\ 0.75(1 + 0.3333*0.4^2)\ ]^2 = 1.5602$$

$$M = 0.3 \Rightarrow A/A^* = (1/0.3)\ [\ 0.75(1 + 0.3333*0.3^2)\ ]^2 = 1.9892$$

$$M = 0.35 \Rightarrow A/A^* = (1/0.35)\ [\ 0.75(1 + 0.3333*0.35^2)\ ]^2 = 1.7410$$

$$M = 0.34 \Rightarrow A/A^* = (1/0.34)\ [\ 0.75(1 + 0.3333*0.34^2)\ ]^2 = 1.7844$$

Now do a linear interpolation for the rest to get $M_E = 0.348$;

Eq. 15.35 $\quad P_E/P_o = [1 + 0.3333*0.348^2\ ]^{-2.5} = 0.9058$

$$P_E = 0.9058 \times 1000 = \mathbf{906\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.43

To what pressure should the steam in problem 15.40 expand to reach Mach one? Use constant specific heats to solve.

Find stagnation properties

$$T_0 = T_1 + \mathbf{V}_1^2/2C_p = 573.15\ \text{K} + 15^2\ (\text{m/s})^2/(2 \times 1872\ \text{J/kgK}) = 573.21\ \text{K}$$

$$P_0 = P_1\ (T_0/T_1)^{k/(k-1)} = 1800\ \text{kPa}\ (573.21/573.15)^{4.058} = 1800.765\ \text{kPa}$$

From Eq.15.35 we get (k = 1.327)

$$P = P_0\ [1 + \frac{k - 1}{2} M^2\ ]^{-k/(k-1)} = 1800.765\ \text{kPa}\ [1 + 0.1635]^{-4.058} = \mathbf{974\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.44

A jet plane travels through the air with a speed of 1000 km/h at an altitude of 6 km, where the pressure is 40 kPa and the temperature is −12°C. Consider the inlet diffuser of the engine where air leaves with a velocity of 100 m/s. Determine the pressure and temperature leaving the diffuser, and the ratio of inlet to exit area of the diffuser, assuming the flow to be reversible and adiabatic.

$\mathbf{V}$ = 1000 km/h = 277.8 m/s, $v_1 = RT/P = 0.287 \times 261.15/40 = 1.874$ m^3/kg

$h_1 = 261.48$ kJ/kg,

$h_{o1} = 261.48 + 277.8^2/2000 = 300.07$ kJ/kg

$\Rightarrow T_{o1} = 299.7$ K,

$P_{o1} = P_1 (T_{o1}/T_1)^{k/(k-1)} = 40 \times (299.7/261.15)^{3.5} = 64.766$ kPa

$h_2 = 300.07 - 100^2/2000 = 295.07$ kJ/kg $\Rightarrow$ $T_2 =$ **294.7 K**,

$P_2 = P_{o1} (T_2/T_{o1})^{k/(k-1)} = 64.766 \times (294.7/299.7)^{3.5} =$ **61 kPa**

$v_2 = RT_2/P_2 = 0.287$ kJ/kg-K $\times$ 294.7 K/61 kPa = 1.386 m^3/kg

$A_1/A_2 = (v_1/v_2)(V_2/V_1) = (1.874/1.386)(100/277.8) =$ **0.487**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.45

Air flows into a convergent-divergent nozzle with an exit area of 1.59 times the throat area of 0.005 m^2. The inlet stagnation state is 1 MPa, 600 K. Find the backpressure that will cause subsonic flow throughout the entire nozzle with M = 1 at the throat. What is the mass flow rate?

This corresponds to case c and is a reversible flow.

$A_E/A^* = 1.59$ Look at top in Table A.12 ($M < 1$)

$M_E = 0.4$ and $P_E/P_o = 0.8956$

$P_E = 0.8956\ P_o = 0.8956 \times 1000$ kPa = **896 kPa**

To find the mass flow rate we have the maximum flow rate from Eq. 15.42,

$$\dot{m} = A^*\ P_o \sqrt{k/RT_o} \times \left[\frac{k+1}{2}\right]^{-(k+1)/2(k-1)}$$

$$= 0.005 \times 1000 \times 1000\ \text{N} \sqrt{1.4/(0.287 \times 600 \times 1000)}\ \text{s/m} \times 1.2^{-2.4/0.8}$$

$$= \mathbf{8.25\ kg/s}$$

Notice kPa must be converted to Pa and also units for RT [kJ/kg = 1000 $(m/s)^2$]

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.46

A nozzle is designed assuming reversible adiabatic flow with an exit Mach number of 2.8 while flowing air with a stagnation pressure and temperature of 2 MPa and 150°C, respectively. The mass flow rate is 5 kg/s, and *k* may be assumed to be 1.40 and constant. Determine the exit pressure, temperature, exit area, and the throat area.

Since $M_E = 2.8$ we must have choked flow with $M^* = 1$, then the mass flow rate is maximum and follows Eq.15.42

$$\dot{m}/A^* = P_o \sqrt{k/RT_o} \times \left[\frac{k+1}{2} \right]^{-(k+1)/2(k-1)}$$

$$= 2000 \times 1000 \text{ N/m}^2 \sqrt{1.4/(0.287 \times 423.15 \times 1000)} \text{ s/m} \times 1.2^{-2.4/0.8}$$

$$= 3929.72 \text{ kg/s-m}^2$$

$$A^* = \dot{m} / (3929.72 \text{ kg/sm}^2) = (5 / 3929.72) \text{ m}^2 = \mathbf{1.272 \times 10^{-3} \ m^2}$$

From Table A.12: $M_E = 2.8$: $T_E / T_o = 0.38941$, $P_E / P_o = 0.036848$

$$A_E = A^* (A_E/A^*) = 1.272 \times 10^{-3} \times 3.5001 = \mathbf{4.452 \times 10^{-3} \ m^2}$$

$$T_E = T_o (T_E / T_o) = 423.15 \text{ K} \times 0.38941 = \mathbf{164.8 \ K}$$

$$P_E = P_o (P_E / P_o) = 2000 \text{ kPa} \times 0.036848 = \mathbf{73.7 \ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.47

An air flow at 600 kPa, 600 K, $M = 0.3$ flows into a convergent-divergent nozzle with $M = 1$ at the throat. Assume a reversible flow with an exit area twice the throat area and find the exit pressure and temperature for subsonic exit flow to exist.

To find these properties we need the stagnation properties from the inlet state

From Table A.12: $M_i = 0.3$: $P_i/P_o = 0.93947$, $T_i/T_o = 0.98232$

$P_o = 600$ kPa/ 0.93947 = 638.66 kPa, $T_o = 600$ K/ 0.98232 = 610.8 K

This flow is case c in Figure 15.13. From Table A.12: $A_E/A^* = 2$

$P_E/P_o = 0.9360$, $T_E/T_o = 0.98127$

$P_E = 0.9360\ P_o = 0.936 \times 638.66$ kPa = **597.8 kPa**

$T_E = 0.98127\ T_o = 0.98127 \times 610.8$ K = **599.4 K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.48

Air at 150 kPa, 290 K expands to the atmosphere at 100 kPa through a convergent nozzle with exit area of 0.01 m^2. Assume an ideal nozzle. What is the percent error in mass flow rate if the flow is assumed incompressible?

$$T_e = T_i \left(\frac{P_e}{P_i}\right)^{\frac{k-1}{k}} = 258.28 \text{ K}$$

$$\mathbf{V}_e^2/2 = h_i - h_e = C_p (T_i - T_e) = 1.004 (290 - 258.28) = 31.83 \text{ kJ/kg}$$

$$\mathbf{V}_e = 252.3 \text{ m/s}; \quad v_e = \frac{RT_e}{P_e} = \frac{0.287 \times 258.28}{100} = 0.7412 \text{ m}^3/\text{kg}$$

$$\dot{m} = A\mathbf{V}_e / v_e = \frac{0.01 \times 252.3}{0.7413} = 3.4 \text{ kg/s}$$

Incompressible Flow: $v_i = RT/P = 0.287 \times 290/150 = 0.55487 \text{ m}^3/\text{kg}$

$$\mathbf{V}_e^2/2 = v\,\Delta P = v_i (P_i - P_e) = 0.55487 (150 - 100) = 27.74 \text{ kJ/kg}$$

$$\Rightarrow \quad \mathbf{V}_e = 235 \text{ m/s} \quad \Rightarrow \quad \dot{m} = A\mathbf{V}_e / v_i = 0.01 \times 235 / 0.55487 = 4.23 \text{ kg/s}$$

$$\frac{\dot{m}_{\text{incompressible}}}{\dot{m}_{\text{compressible}}} = \frac{4.23}{3.4} = 1.25$$

about **25% overestimation.**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.49

Find the exit pressure and temperature for supersonic exit flow to exist in the nozzle flow of Problem 15.47.

We assume a reversible as the possibility which is case d in Figure 15.13.

To find these properties we need the stagnation properties from the inlet state

From Table A.12: $M_i = 0.3$: $P_i/P_o = 0.93947$, $T_i/T_o = 0.98232$

$P_o = 600$ kPa/ 0.93947 = 638.66 kPa, $T_o = 600$ K/ 0.98232 = 610.8 K

From Table A.12: $A_E/A^* = 2$, $P_E/P_o = 0.09352$, $T_E/T_o = 0.50813$

$P_E = 0.09352\ P_o = 0.09352 \times 638.66 =$ **59.7 kPa**

$T_E = 0.50813\ T_o = 0.50813 \times 610.8 =$ **310.4 K**

This is significant lower P and T, but then we also have M = 2.2

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.50

Air is expanded in a nozzle from a stagnation state of 2 MPa, 600 K to a backpressure of 1.9 MPa. If the exit cross-sectional area is 0.003 m^2, find the mass flow rate.

This corresponds to case c and is a reversible flow.

$P_E/P_{ox} = 1.9/2.0 = 0.95 \quad \Rightarrow$ Table A.12: $\quad M_E = 0.268$

$T_E = (T/T_o)_E \, T_o = 0.9854 \times 600 = 591.2$ K

$c_E = \sqrt{kRT_E} = \sqrt{1.4 \times 1000 \times 0.287 \times 591.2} = 487.4$ m/s

$\mathbf{V}_E = M_E c_E = 0.268 \times 487.4 = 130.6$ m/s

$v_E = RT/P = 0.287$ kJ/kg-K $\times$ 591.2 K/1900 kPa = 0.0893 m^3/kg

$\dot{m} = A_E \mathbf{V}_E / v_E = 0.003$ m^2 $\times$ 130.6 (m/s)/0.0893 m^3/kg = **4.387 kg/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.51

A 1-m^3 insulated tank contains air at 1 MPa, 560 K. The tank is now discharged through a small convergent nozzle to the atmosphere at 100 kPa. The nozzle has an exit area of 2×10^{-5} m^2.

a. Find the initial mass flow rate out of the tank.

b. Find the mass flow rate when half the mass has been discharged.

a. The back pressure ratio:

$$P_B/P_{o1} = 100/1000 = 0.1 < (P^*/P_o)_{crit} = 0.5283$$

so the initial flow is choked with the maximum possible flow rate.

$$M_E = 1 \; ; \; P_E = 0.5283 \times 1000 = 528.3 \text{ kPa}$$

$$T_E = T^* = 0.8333 \times 560 \text{ K} = 466.7 \text{ K}$$

$$\mathbf{V}_E = c = \sqrt{kRT^*} = \sqrt{1.4 \times 1000 \times 0.287 \times 466.7} = 433 \text{ m/s}$$

$$v_E = RT^*/P_E = 0.287 \text{ kJ/kg-K} \times 466.7 \text{ K}/528.3 \text{ kPa} = 0.2535 \text{ m}^3/\text{kg}$$

$$\dot{m}_1 = AV_E/v_E = 2\times10^{-5} \text{ m}^2 \times 433 \text{ (m/s)}/0.2535 \text{ m}^3/\text{kg} = \mathbf{0.0342 \text{ kg/s}}$$

b. The initial mass is

$$m_1 = P_1V/RT_1 = 1000 \times 1/(0.287 \times 560) = 6.222 \text{ kg}$$

with a mass at state 2 as $m_2 = m_1/2 = 3.111$ kg.

Assume an adiabatic reversible expansion of the mass that remains in the tank.

$$P_2 = P_1(v_1/v_2)^k = 100 \times 0.5^{1.4} = 378.9 \text{ kPa}$$

$$T_2 = T_1(v_1/v_2)^{k-1} = 560 \times 0.5^{0.4} = 424 \text{ K}$$

The pressure ratio is still less than critical and the flow thus choked.

$$P_B/P_{o2} = 100/378.9 = 0.264 < (P^*/P_o)_{crit}$$

$$M_E = 1 \; ; \; P_E = 0.5283 \times 378.9 = 200.2 \text{ kPa}$$

$$T_E = T^* = 0.8333 \times 424 = 353.7 \text{ K}$$

$$\mathbf{V}_E = c = \sqrt{kRT^*} = \sqrt{1.4 \times 1000 \times 0.287 \times 353.7} = 377 \text{ m/s}$$

$$\dot{m}_2 = A\mathbf{V}_E P_E/RT_E = \frac{2\times10^{-5}(377)(200.2)}{0.287(353.7)} = \mathbf{0.0149 \text{ kg/s}}$$

We could also have found the two mass flow rates from Eq. 15.42 without finding the exit plane conditions.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.52

A convergent-divergent nozzle has a throat diameter of 0.05 m and an exit diameter of 0.1 m. The inlet stagnation state is 500 kPa, 500 K. Find the back pressure that will lead to the maximum possible flow rate and the mass flow rate for three different gases as: air; hydrogen or carbon dioxide.

There is a maximum possible flow when M = 1 at the throat,

$$T^* = \frac{2}{k+1} T_o; \quad P^* = P_o \left(\frac{2}{k+1}\right)^{\frac{k}{k-1}}; \qquad \rho^* = \rho_o \left(\frac{2}{k+1}\right)^{\frac{1}{k-1}}$$

$$\dot{m} = \rho^* A^* V = \rho^* A^* c = P^* A^* \sqrt{k/RT^*}$$

$$A^* = \pi D^2/4 = 0.001963 \text{ m}^2$$

	k	T^*	P^*	c	ρ^*	$\dot{m}$

c)	1.289	436.9	273.9	348.9	3.318	2.273

$A_E/A^* = (D_E/D^*)^2 = 4$. There are 2 possible solutions corresponding to points c and d in Fig. 15.13 and Fig. 15.17. For these we have

	Subsonic solution		Supersonic solution	
	M_E	P_E/P_o	M_E	P_E/P_o
a)	0.1466	0.985	2.940	0.0298
b)	0.1464	0.985	2.956	0.0293
c)	0.1483	0.986	2.757	0.0367

$P_B = P_E \cong 0.985 \times 500 = 492.5$ kPa all cases point c

a) $P_B = P_E = 0.0298 \times 500 = 14.9$ kPa, point d

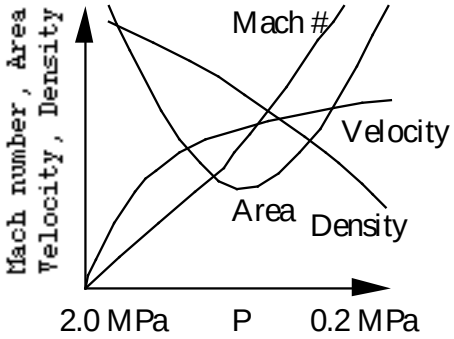
b) $P_B = P_E = 0.0293 \times 500 = 14.65$ kPa, point d

c) $P_B = P_E = 0.0367 \times 500 = 18.35$ kPa, point d

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.53

Air is expanded in a nozzle from a stagnation state of 2 MPa, 600 K, to a static pressure of 200 kPa. The mass flow rate through the nozzle is 5 kg/s. Assume the flow is reversible and adiabatic and determine the throat and exit areas for the nozzle.



$$P^* = P_o \left(\frac{2}{k+1}\right)^{\frac{k}{k-1}}$$

$$= 2 \times 0.5283 = 1.056 \text{ MPa}$$

$$T^* = T_o \times \frac{2}{k+1} = 600 \times 0.8333 = 500 \text{ K}$$

$$v^* = RT^*/P^* = 0.287 \times 500/1056$$

$$= 0.1359 \text{ m}^3/\text{kg}$$

The critical speed of sound is

$$c^* = \sqrt{kRT^*} = \sqrt{1.4 \times 1000 \times 0.287 \times 500} = 448.2 \text{ m/s}$$

$$A^* = \dot{m}v^*/c^* = 5 \times 0.1359/448.2 = \mathbf{0.00152\ m^2}$$

$$P_2/P_o = 200/2000 = 0.1 \quad \Rightarrow \quad M_2^* = 1.701 = \mathbf{V}_2/c^*$$

We used the column in Table A.12 with mach no. based on throat speed of sound.

$$\mathbf{V}_2 = 1.701 \times 448.2 = 762.4 \text{ m/s}$$

$$T_2 = T_o\,(T_2/T_o) = 600 \times 0.5176 = 310.56 \text{ K}$$

$$v_2 = RT_2/P_2 = 0.287 \text{ kJ/kg-K} \times 310.56 \text{ K}/200 \text{ kPa} = 0.4456 \text{ m}^3/\text{kg}$$

$$A_2 = \dot{m}v_2/\mathbf{V}_2 = 5 \text{ kg/s} \times 0.4456 \text{ (m}^3\text{/kg)} / 762.4 \text{ m/s} = \mathbf{0.00292\ m^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.54

Air flows into a convergent-divergent nozzle with an exit area of 2.0 times the throat area of 0.005 m^2. The inlet stagnation state is 1.2 MPa, 600 K. Find the backpressure that will cause a reversible supersonic exit flow with M = 1 at the throat. What is the mass flow rate?

This flow is case d in Fig.15.17 the only reversible supersonic flow.

$$A_E/A^* = 2 \quad \text{see Table A.12} \quad (M > 1)$$

$$\Rightarrow \quad M_E = 2.2 \quad \text{and} \quad P_E/P_o = 0.09399$$

$$P_E = 0.09399 \times 1200 = \mathbf{112.8\ kPa}$$

Using Eq.15.42 for the chocked flow rate

$$\dot{m} = A^* P_o \sqrt{k/RT_o} \times \left[\frac{k+1}{2} \right]^{-(k+1)/2(k-1)}$$

$$= 0.005 \times 1200 \times 1000 \sqrt{1.4/(0.287 \times 600 \times 1000)} \times 1.2^{-2.4/0.8}$$

$$= \mathbf{9.9\ kg/s}$$

Notice kPa must be converted to Pa and also units for RT [kJ/kg = 1000 $(m/s)^2$]

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.55

What is the exit pressure that will allow a reversible subsonic exit flow in the previous problem?

This flow is case c in Fig.15.17 (and c in Fig. 15.13) the only reversible subsonic flow with M = 1 at the throat.

$$A_E/A^* = 2 \quad \text{see Table A.12} \quad (M < 1)$$

$$P_E/P_o = 0.9360, \quad T_E/T_o = 0.98127$$

$$P_E = 0.9360\ P_o = 0.936 \times 1200 = \mathbf{1123\ kPa}$$

$$(\quad T_E = 0.98127\ T_o = 0.98127 \times 600 = 588.8\ \text{K}\ )$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.56

A flow of helium flows at 500 kPa, 500 K with 100 m/s into a convergent-divergent nozzle. Find the throat pressure and temperature for reversible flow and $M = 1$ at the throat.

We need to find the stagnation properties first (k = 1.667)

$$T_o = T_1 + \mathbf{V}_1^2/2C_p = 500 + 100^2/(2 \times 5193) = 500.963 \text{ K}$$

$$P_o = P_1 (T_0/T_1)^{k/(k-1)} = 500 (500.963/500)^{2.5} = 502.41 \text{ kPa}$$

From the analysis we get Eqs.15.37-38

$$P^* = P_o \left(\frac{2}{k+1}\right)^{k/(k-1)} = 502.41 \left(\frac{2}{1.667+1}\right)^{2.5} = \mathbf{244.7\ kPa}$$

$$T^* = T_o \frac{2}{k+1} = 500.963 \times \frac{2}{1.667+1} = \mathbf{375.7\ K}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.57

Assume the same tank and conditions as in Problem 15.51. After some flow out the nozzle flow changes to become subsonic. Find the mass in the tank and the mass flow rate out at that instant.

The initial mass is

$$m_1 = P_1V/RT_1 = 1000 \times 1/(0.287 \times 560) = 6.222 \text{ kg}$$

The flow changes to subsonic when the pressure ratio reaches critical.

$$P_B/P_{o3} = 0.5283 \Rightarrow P_{o3} = 189.3 \text{ kPa}$$

$$v_1/v_3 = (P_{o3}/P_1)^{1/k} = (189.3/1000)^{0.7143} = 0.3046$$

$$m_3 = m_1 v_1/v_3 = 6.222 \times 0.3046 = \mathbf{1.895\ kg}$$

At this point the tank temperatures is (assuming isentropic expansion)

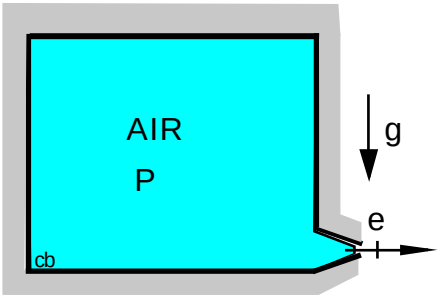
$$T_3 = T_1(v_1/v_3)^{k-1} = 560 \times 0.3046^{0.4} = 348 \text{ K}$$

$$P_E = P_B = 100 \text{ kPa} \; ; \quad M_E = 1$$

$$T_E = 0.8333 \times 348 = 290 \text{ K} \; ; \quad \mathbf{V}_E = \sqrt{kRT_E} = 341.4 \text{ m/s}$$

$$\dot{m}_3 = A\mathbf{V}_E P_E/RT_E = \frac{2\times10^{-5}(341.4)(100)}{0.287(290)} = \mathbf{0.0082\ kg/s}$$

We could have used Eq.15.42 with $P_o = P_{o3} = 189.3$ kPa, $T_o = T_3 = 348$ K



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.58

A given convergent nozzle operates so it is choked with stagnation inlet flow properties of 400 kPa, 400 K. To increase the flow, a reversible adiabatic compressor is added before the nozzle to increase the stagnation flow pressure to 500 kPa. What happens to the flow rate?

Since the nozzle is choked the mass flow rate is given by Eq.15.42. The compressor changes the stagnation pressure and temperature.

Isentropic: $P_{o\,new} = P_o\, r_p$ and $T_{o\,new} = T_o \left(r_p\right)^{\frac{k-1}{k}}$

$$P_{o\,new} / \sqrt{T_{o\,new}} = \left(r_p\right)^{\frac{k+1}{2k}} \left[P_o / \sqrt{T_o}\right]$$

so the mass flow rate is multiplied with the factor

$$\left(r_p\right)^{\frac{k+1}{2k}} = \left(\frac{500}{400}\right)^{\frac{2.4}{2.8}} = 1.21$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.59

A 1-m^3 uninsulated tank contains air at 1 MPa, 560 K. The tank is now discharged through a small convergent nozzle to the atmosphere at 100 kPa while heat transfer from some source keeps the air temperature in the tank at 560 K. The nozzle has an exit area of 2×10^{-5} m^2.

a. Find the initial mass flow rate out of the tank.

b. Find the mass flow rate when half the mass has been discharged.

a. The back pressure ratio:

$$P_B/P_{o1} = 100/1000 = 0.1 < (P^*/P_o)_{crit} = 0.5283$$

so the initial flow is choked with the maximum possible flow rate given in Eq.15.42

$$\dot{m} = A^* P_o \sqrt{k/RT_o} \times \left[\frac{k+1}{2}\right]^{-(k+1)/2(k-1)}$$

$$= 2 \times 10^{-5} \times 1 \times 10^6 \sqrt{1.4/(0.287 \times 560 \times 1000)} \times 1.2^{-2.4/0.8}$$

$$= \mathbf{0.034\ kg/s}$$

b. The initial mass is

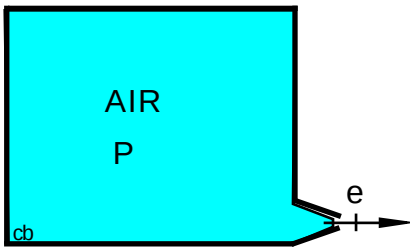
$$m_1 = P_1 V/RT_1 = 1000 \times 1/(0.287 \times 560) = 6.222\ \text{kg}$$

with a mass at state 2 as $m_2 = m_1/2 = 3.111$ kg.

$P_2 = P_1/2 = 500$ kPa ; $T_2 = T_1$; $P_B/P_2 = 100/500 = 0.2 < (P^*/P_o)_{crit}$

The flow is choked and the mass flow rate is similar to the previously stated one but with half the stagnation pressure (same stagnation temperature):

$$\dot{m}_2 = A^* P_o \sqrt{k/RT_o} \times \left[\frac{k+1}{2}\right]^{-(k+1)/2(k-1)} = \dot{m}_1 / 2 = \mathbf{0.017\ kg/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.60

Assume the same tank and conditions as in Problem 15.59. After some flow out the nozzle flow changes to become subsonic. Find the mass in the tank and the mass flow rate out at that instant.

The initial mass is

$$m_1 = P_1V/RT_1 = 1000 \times 1/(0.287 \times 560) = 6.222 \text{ kg}$$

Flow changes to subsonic when the pressure ratio reaches critical.

$P_B/P_{o3} = 0.5283$; $P_3 = P_{o3} = P_B/0.5283 = 100/0.5283 = 189.3$ kPa

$m_3 = m_1P_3/P_1 =$ **1.178 kg** ;

$T_3 = T_1$

$T_E = T^* = 0.8333 \times 560 = 466.7$ K, $P_E = P_B = 100$ kPa

$$\mathbf{V}_E = c = \sqrt{kRT^*} = \sqrt{1.4 \times 1000 \times 0.287 \times 466.7} = 433 \text{ m/s}$$

$$\dot{m}_3 = A\mathbf{V}_E P_E/RT_E = \frac{2\times10^{-5}(433)(100)}{0.287(466.7)} = \textbf{0.00646 kg/s}$$

Flow is critical so we could have used Eq.15.42 with $P_o = 189.3$ kPa, $T_o = 560$ K

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Normal Shocks

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.61

The products of combustion, use air, enter a convergent nozzle of a jet engine at a total pressure of 125 kPa, and a total temperature of 650°C. The atmospheric pressure is 45 kPa and the flow is adiabatic, with a rate of 25 kg/s. Determine the exit area of the nozzle.

The critical pressure Table 15.1: $P_{crit} = P_2 = 125 \times 0.5283 = 66$ kPa > P_{amb}

The flow is then choked with M = 1 at the exit and a pressure drop outside of the nozzle.

$T_2 = 923.15 \times 0.8333 = 769.3$ K

$\mathbf{V}_2 = c_2 = \sqrt{1.4 \times 1000 \times 0.287 \times 769.3} = 556$ m/s

$v_2 = RT_2/P_2 = 0.287 \times 769.3/66 = 3.3453$ m^3/kg

$A_2 = \dot{m} v_2 / \mathbf{V}_2 = 25 \times 3.3453/556 =$ **0.1504 m^2**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.62

Redo the previous problem for a mixture with k = 1.3 and molecular mass of 31.

The critical pressure Table 15.1: $P_{crit} = P_2 = 125 \times 0.5457 = 68.2$ kPa > P_{amb}

The flow is then choked. $T_2 = 923.15 \times 0.8696 = 802.8$ K

The gas constant is R = 8.31451 / 31 = 0.2682 kJ/kg-K

$$\mathbf{V}_2 = c_2 = \sqrt{1.3 \times 1000 \times 0.2682 \times 802.8} = 529 \text{ m/s}$$

$$v_2 = RT_2/P_2 = 0.2682 \times 802.8/68.2 = 3.157 \text{ m}^3/\text{kg}$$

$$A_2 = \dot{m}v_2 / \mathbf{V}_2 = 25 \times 3.157/529 = \mathbf{0.149\ m^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.63

At what Mach number will the normal shock occur in the nozzle of Problem 15.52 flowing with air if the back pressure is halfway between the pressures at *c* and *d* in Fig. 15.17?

First find the two pressures that will give exit at c and d. See solution to 15.52 a)

$A_E/A^* = (D_E/D^*)^2 = 4 \quad \Rightarrow$

For case c: $P_E = 492.5$ kPa For case d: $P_E = 14.9$ kPa

Actual case: $P_E = (492.5 + 14.9)/2 = 253.7$ kPa

Assume $M_x = 2.4 \Rightarrow \quad M_y = 0.5231$; $\quad P_{oy}/P_{ox} = 0.54015$

$A_x/A_x^* = 2.4031$; $\quad A_x/A_y^* = 1.298$

Work backwards to get P_E:

$A_E/A_y^* = (A_E/A_x^*)\,(A_x/A_y^*) \,/\, (A_x/A_x^*) = 4 \times 1.298/2.4031 = 2.1605$

$\Rightarrow \quad M_E = 0.2807$; $\quad P_E/P_{oy} = 0.94675$

$P_E = (P_E/P_{oy})\,(P_{oy}/P_{ox})\,P_{ox} = 0.94675 \times 0.54015 \times 500 = 255.7$ kPa

Repeat if $M_x = 2.5 \quad \Rightarrow \quad P_E = 233.8$ kPa

Interpolate to match the desired pressure => $M_x =$ **2.41**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.64

Consider the nozzle of Problem 15.53 and determine what back pressure will cause a normal shock to stand in the exit plane of the nozzle. This is case g in Fig. 15.17. What is the mass flow rate under these conditions?

We assume reversible flow up to the shock

Table A.12: $P_E/P_o = 200/2000 = 0.1$; $M_E = 2.1591 = M_x$

Shock functions Table A.13: $M_y = 0.5529$; $P_y/P_x = 5.275$

$P_B = P_y = 5.275 \times P_x = 5.275 \times 200 =$ **1055 kPa**

$\dot{m} =$ **5 kg/s** same as in Problem 15.53 since M = 1 at throat.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.65

A normal shock in air has upstream total pressure of 500 kPa, stagnation temperature of 500 K and M_x = 1.4. Find the downstream stagnation pressure.

From the normal shock relations in Section 15.8 found in Table A.13 we get

M_x = 1.4: $\quad P_{oy}/P_{ox} = 0.95819$

$P_{oy} = 0.\ 95819\ P_{ox} = 0.\ 95819 \times 500 =$ **479.1 kPa**

Remark: The stagnation temperature would be unchanged (energy equation).

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.66

How much entropy per kg flow is generated in the shock in Example 15.9?

The change in entropy is

$$s_{gen} = s_y - s_x = C_p \ln \frac{T_y}{T_x} - R \ln \frac{P_y}{P_x}$$

$$= 1.004 \ln 1.32 - 0.287 \ln 2.4583$$

$$= 0.27874 - 0.25815 = \mathbf{0.0206\ kJ/kg\ K}$$

Notice that this function could have been tabulated also as

$$s_{gen}/R = \frac{k}{k-1} \ln \frac{T_y}{T_x} - \ln \frac{P_y}{P_x}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.67

Consider the diffuser of a supersonic aircraft flying at $M = 1.4$ at such an altitude that the temperature is −20°C, and the atmospheric pressure is 50 kPa. Consider two possible ways in which the diffuser might operate, and for each case calculate the throat area required for a flow of 50 kg/s.

a. The diffuser operates as reversible adiabatic with subsonic exit velocity.

b. A normal shock stands at the entrance to the diffuser. Except for the normal shock the flow is reversible and adiabatic, and the exit velocity is subsonic. This is shown in Fig. P15.67.

a. Assume a convergent-divergent diffuser with $M = 1$ at the throat. Remember that for the supersonic flow the convergent front will reduce the velocity.

Relate the inlet state to the stagnation state state table A.12 with $M = 1.4$:

$$P/P_o = 0.31424 \quad \Rightarrow \quad P_o = 50 \text{ kPa} / 0.31424 = 159.11 \text{ kPa}$$

$$T/T_o = 0.71839 \quad \Rightarrow \quad T_o = 253.15 \text{ K} / 0.71839 = 352.385 \text{ K}$$

The maximum flow rate for chocked flow from Eq.15.42

$$\dot{m}/A^* = P_o \sqrt{k/RT_o} \times \left[\frac{k+1}{2}\right]^{-(k+1)/2(k-1)}$$

$$= 159.11 \times 10^3 \sqrt{1.4/(0.287 \times 253.15 \times 1000)} \times 1.2^{-2.4/0.8}$$

$$= 342.59 \text{ kg/sm}^2$$

$$A^* = \dot{m}/342.59 \text{ kg/sm}^2 = \mathbf{0.1459\ m^2}$$

b. Across the shock we have, $M_x = 1.4$ so from Table A.13

$$M_y = 0.7397 \ ; \quad P_{oy}/P_{ox} = 0.95819 \ ;$$

The stagnation properties after the shock are:

$$T_{oy} = T_{ox} = 253.15 / 0.71839 = 352.385 \text{ K (as before)}$$

$$P_{oy} = P_{ox} \times 0.95819 = (50 \text{ kPa} / 0.31424) \times 0.95819 = 152.46 \text{ kPa}$$

Only the stagnation pressure changed due to the shock so Eq.15.42 gives

$$\dot{m}/A^* = 0.95819 \times 342.59 \text{ kg/sm}^2 = 328.266 \text{ kg/sm}^2$$

$$A^* = \dot{m}/328.266 \text{ kg/sm}^2 = \mathbf{0.1523\ m^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.68

A flow into a normal shock in air has a total pressure 400 kPa, stagnation temperature of 600 K and $M_x = 1.2$. Find the upstream temperature T_x, the specific entropy generation in the shock and the downstream velocity.

From Table A.12: $M_x = 1.2$ has $T_x/T_o = 0.7764$, $P_x/P_o = 0.41238$

$$T_x = 0.7764\ T_o = 0.7764 \times 600\ \text{K} = \mathbf{465.84\ K}$$

From Table A.13: $T_y/T_x = 1.128$, $P_y/P_x = 1.5133$, $M_y = 0.84217$

The change in entropy is

$$s_{gen} = s_y - s_x = C_p \ln \frac{T_y}{T_x} - R \ln \frac{P_y}{P_x}$$

$$= 1.004 \ln 1.128 - 0.287 \ln 1.5133$$

$$= 0.12093 - 0.11890 = \mathbf{0.00203\ kJ/kg\ K}$$

From the shock relations we had

$$T_y = 1.128\ T_x = 1.128 \times 465.84\ \text{K} = 525.47\ \text{K}$$

$$\mathbf{V}_y = M_y\, c_y = M_y \sqrt{kRT_y} = 0.84217 \sqrt{1.4 \times 0.287 \times 525.47 \times 1000}$$

$$= 0.84217 \times 459.49 = \mathbf{387\ m/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.69

Consider the nozzle in problem 15.42 flowing helium. What should the backpressure be for a normal shock to stand at the exit plane? This is case g in Fig.15.17. What is the exit velocity after the shock?

Reversible flow up to the shock with M = 1 at the throat.

$$P_{x\,o} = P_o, \quad T_{x\,o} = T_o, \qquad A_E/A^* = 175 / 100 = 1.75$$

As we do not have a Table 12 made for helium (k = 5/3 = 1.667) we need to use the formulas. The area to M relation is given in Eq.15.43 so

$$A/A^* = 1.75 = (1/M_x)\left[\frac{2}{k+1}\left(1 + (1/3)M_x^2\right)\right]^2 = [3 + M_x^2\,]^2 /16\, M_x$$

There are two solutions and we need the one with $M_x > 1$, see fig 15.10 we should expect a solution around $M_x = 2$. With trial and error on

$$3 + M_x^2 = \sqrt{16 \times 1.75\, M_x} \quad \text{which gives } M_x = 2.2033$$

Now we can do the normal shock from Eq.15.53

$$M_x = 2.2033 \;\Rightarrow\; M_y^2 = \frac{2.2033^2 + 3}{5 \times 2.2033^2 - 1} = 0.3375,$$

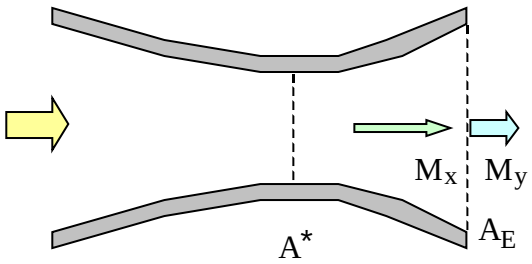
The temperature ratio from Eq. 15.49 and the T_x from Eq. 15.34:

$$T_y = T_x \frac{1 + 0.5(k\text{-}1)\, M_x^2}{1 + 0.5(k\text{-}1)\, M_y^2} = \frac{T_{x\,o}}{1 + 0.5(k\text{-}1)\, M_y^2} = \frac{375}{1 + 0.333 \times 0.3375} = 337.1$$

K

$$\mathbf{V}_y = M_y\, c_y = M_y \sqrt{kRT_y} = \sqrt{0.3375} \times \sqrt{1.667 \times 2.0771 \times 337.1 \times 1000}$$

$$= 0.58095 \times 1080.4 = \mathbf{627.6\ m/s}$$



Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.70

Find the specific entropy generation in the shock of the previous Problem.

Reversible flow up to the shock with M = 1 at the throat.

$P_{x\,o} = P_o$, $T_{x\,o} = T_o$, $A_E/A^* = 175 / 100 = 1.75$

Table A.12: $M_E = M_x = 2.042$, $P_x/P_{o\,x} = 0.12$, $T_x/T_{o\,x} = 0.5454$

Now we can do the normal shock from Table A.13

$M_x = 2.042 \Rightarrow M_y = 0.5704$, $P_y/P_x = 4.6984$, $T_y/T_x = 1.7219$

The change in entropy is

$$s_{gen} = s_y - s_x = C_p \ln \frac{T_y}{T_x} - R \ln \frac{P_y}{P_x}$$

$$= 1.004 \ln 1.7219 - 0.287 \ln 4.6984$$

$$= 0.5456 - 0.44405 = \mathbf{0.1015\ kJ/kg\ K}$$

15.71

Steam at 600 kPa, 300°C is fed to a set of convergent nozzles in a steam turbine. The total nozzle exit area is 0.005 m^2 and they have a discharge coefficient of 0.94. The mass flow rate should be estimated from the measurement of the pressure drop across the nozzles, which is measured to be 200 kPa. Determine the mass flow rate.

Inlet B.1.3 $h_i = 3061.6$ kJ/kg, $s_i = 7.3724$ kJ/kg K

Exit: $(P_e, s_{e,s})$ $P_e = P_i - 200 = 400$ kPa, $s_{e,s} = s_i = 7.3724$ kJ/kg K

$\Rightarrow h_{e,s} = 2961$ kJ/kg and $v_{e,s} = 0.5932$ m^3/kg,

$$\mathbf{V}_{e,s} = \sqrt{2 \times 1000(3061.6 - 2961)} = 448.55 \text{ m/s}$$

$$\dot{m}_s = A\mathbf{V}_{e,s}/v_{e,s} = 0.005 \times 448.55/0.5932 = 3.781 \text{ kg/s}$$

$$\dot{m}_a = C_D \dot{m}_s = 0.94 \times 3.781 = \mathbf{3.554\ kg/s}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.72

Air enters a diffuser with a velocity of 200 m/s, a static pressure of 70 kPa, and a temperature of –6°C. The velocity leaving the diffuser is 60 m/s and the static pressure at the diffuser exit is 80 kPa. Determine the static temperature at the diffuser exit and the diffuser efficiency. Compare the stagnation pressures at the inlet and the exit.

Stagnation T at the inlet

$$T_{o1} = T_1 + \mathbf{V}_1^2/2C_p = 267.15 + 200^2/(2000 \times 1.004) = 287.1 \text{ K}$$

Energy Eq. gives the same stagnation T at exit

$$T_{o2} = T_{o1} \Rightarrow T_2 = T_{o2} - \mathbf{V}_2^2/2C_p = 287.1 - 60^2/(2000 \times 1.004) = 285.3 \text{ K}$$

$$\frac{T_{o1} - T_1}{T_1} = \frac{k-1}{k}\frac{P_{o1} - P_1}{P_1} \quad \Rightarrow \quad P_{o1} - P_1 = 18.25 \Rightarrow P_{o1} = 88.3 \text{ kPa}$$

$$\frac{T_{o2} - T_2}{T_2} = \frac{k-1}{k}\frac{P_{o2} - P_2}{P_2} \quad \Rightarrow \quad P_{o2} - P_2 = 1.77 \Rightarrow P_{o2} = 81.8 \text{ kPa}$$

$$T_s^{ex} = T_1 (P_{o2}/P_1)^{k-1/k} = 267.15 \times 1.0454 = \mathbf{279.3\ K}$$

$$\eta_D = \frac{T_s^{ex} - T_1}{T_{o1} - T_1} = \frac{279.3 - 267.15}{287.1 - 267.15} = \mathbf{0.608}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.73

Repeat Problem 15.44 assuming a diffuser efficiency of 80%.

$\mathbf{V}$ = 1000 km/h = 277.8 m/s, $v_1 = RT/P = 0.287 \times 261.15/40 = 1.874$ m^3/kg

$h_1 = 261.48$ kJ/kg,

$h_{o1} = 261.48 + 277.8^2/2000 = 300.07$ kJ/kg

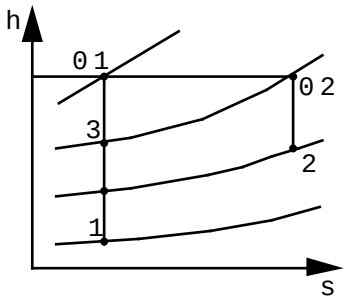
$\Rightarrow T_{o1} = 299.7$ K,

$P_{o1} = P_1 (T_{o1}/T_1)^{k/(k-1)} = 40 \times (299.7/261.15)^{3.5} = 64.766$ kPa

Same as problem 15.44, except
$\eta_D = 0.80$. We thus have from 15.44

$$\frac{h_3 - h_1}{h_{o1} - h_1} = \frac{h_3 - 261.48}{300.07 - 261.48} = 0.8$$

$\Rightarrow h_3 = 292.35$ kJ/kg, $T_3 = 291.9$ K



$P_{o2} = P_3 = P_1 (T_3/T_1)^{k/(k-1)}$

$= 40 (291.9/261.15)^{3.5} = 59.06$ kPa

$T_{o2} = T_{o1} = 299.7$ K

$h_2 = 300.07 - 100^2/2000 = 295.07$ kJ/kg $\Rightarrow T_2 =$ **294.7 K**,

$P_2 = P_{o2} (T_2/T_{o1})^{k/(k-1)} = 59.06 \times (294.7/299.7)^{3.5} =$ **55.68 kPa**

$v_2 = RT_2/P_2 = 0.287 \times 294.7/55.68 = 1.519$ m^3/kg

$A_1/A_2 = (v_1/v_2)(V_2/V_1) = (1.874/1.519)\ (100/277.8) =$ **0.444**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.74

A sharp-edged orifice is used to measure the flow of air in a pipe. The pipe diameter is 100 mm and the diameter of the orifice is 25 mm. Upstream of the orifice, the absolute pressure is 150 kPa and the temperature is 35°C. The pressure drop across the orifice is 15 kPa, and the coefficient of discharge is 0.62. Determine the mass flow rate in the pipeline.

$$\Delta T = T_i \left(\frac{k-1}{k}\right)\frac{\Delta P}{P_i} = 308.15 \times \frac{0.4}{1.4} \times \frac{15}{150} = 8.8 \text{ K}$$

$$v_i = RT_i/P_i = 0.5896 \text{ m}^3/\text{kg}$$

$$P_e = 135 \text{ kPa}, \quad T_e = 299.35 \text{ K}, \quad v_e = 0.6364 \text{ m}^3/\text{kg}$$

$$\dot{m}_i = \dot{m}_e \Rightarrow \quad \mathbf{V}_i / \mathbf{V}_e = (D_e/D_i)^2 \, v_i/v_e = 0.0579$$

$$h_i - h_e = \mathbf{V}_e^2(1 - 0.0579^2)/2 = C_p(T_i - T_e)$$

$$\mathbf{V}_{e\,s} = \sqrt{2 \times 1000 \times 1.004 \times 8.8/(1 - 0.0579)^2} = 133.1 \text{ m/s}$$

$$\dot{m} = C_D \, A\mathbf{V}/v = 0.62 \, (\pi/4) \, (0.025)^2 \, 133.1 / 0.6364 = \mathbf{0.06365 \text{ kg/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.75

A critical nozzle is used for the accurate measurement of the flow rate of air. Exhaust from a car engine is diluted with air so its temperature is 50°C at a total pressure of 100 kPa. It flows through the nozzle with throat area of 700 mm^2 by suction from a blower. Find the needed suction pressure that will lead to critical flow in the nozzle and the mass flow rate.

$P^* = 0.5283\ P_o =$ **52.83 kPa**, $T^* = 0.8333\ T_o = 269.3$ K

$v^* = RT^*/P^* = 0.287 \times 269.3/52.83 = 1.463\ m^3/kg$

$c^* = \sqrt{kRT^*} = \sqrt{1.4 \times 1000 \times 0.287 \times 269.3} = 328.9$ m/s

$\dot{m} = Ac^*/v^* = 700 \times 10^{-6} \times 328.9/1.463 =$ **0.157 kg/s**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.76

Air is expanded in a nozzle from 700 kPa, 200°C, to 150 kPa in a nozzle having an efficiency of 90%. The mass flow rate is 4 kg/s. Determine the exit area of the nozzle, the exit velocity, and the increase of entropy per kilogram of air. Compare these results with those of a reversible adiabatic nozzle.

$T_{2s} = T_1(P_2/P_1)^{(k-1)/k} = 473.2\ (150/700)^{0.286} = 304.6$ K

$\mathbf{V}_{2s}^{\ 2} = 2 \times 1000 \times 1.004(473.2 - 304.6) = 338\ 400$ J/kg

$\mathbf{V}_2^{\ 2} = 0.9 \times 338\ 400\ \text{m}^2/\text{s}^2 \Rightarrow \mathbf{V}_2 = \mathbf{552\ m/s}$

$h_2 + \mathbf{V}_2^2/2 = h_1 \Rightarrow T_2 = T_1 - \mathbf{V}_2^2/2C_p$

$T_2 = 473.2 - 552^2/(2 \times 1000 \times 1.004) = 321.4$ K ;

$v_2 = RT/P = 0.287\ \text{kJ/kg} \times 321.4\ \text{K}/150\ \text{kPa} = 0.6149\ \text{m}^3/\text{kg}$

$A_2 = \dot{m}\, v_2/\mathbf{V}_2 = 4\ \text{kg/s} \times 0.6149\ \text{m}^3/\text{kg}\ /(552\ \text{m/s}) = 0.00446\ \text{m}^2 = \mathbf{4460\ mm^2}$

$s_2 - s_1 = 1.0035 \ln\left(\frac{321.4}{473.2}\right) - 0.287 \ln\left(\frac{150}{700}\right) = \mathbf{0.0539\ kJ/kg\ K}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.77

Steam at a pressure of 1 MPa and temperature of 400°C expands in a nozzle to a pressure of 200 kPa. The nozzle efficiency is 90% and the mass flow rate is 10 kg/s. Determine the nozzle exit area and the exit velocity.

First do the ideal reversible adiabatic nozzle

$$s_{2s} = s_1 = 7.4651 \text{ kJ/kg K}, \quad h_1 = 3263.9 \text{ kJ/kg}$$

$$\Rightarrow \quad T_{2s} = 190.4°\text{C} ; \quad h_{2s} = 2851 \text{ kJ/kg}$$

Now the actual nozzle can be calculated

$$h_1 - h_{2ac} = \eta_D(h_1 - h_{2s}) = 0.9(3263.9 - 2851) = 371.6 \text{ kJ/kg}$$

$$h_{2ac} = 2892.3 \text{ kJ/kg}, \quad T_2 = 210.9°\text{C}, \quad v_2 = 1.1062 \text{ m}^3/\text{kg}$$

$$\mathbf{V}_2 = \sqrt{2000(3263.9 - 2892.3)} = \mathbf{862 \text{ m/s}}$$

$$A_2 = \dot{m}v_2/\mathbf{V}_2 = 10 \text{ kg/s} \times 1.1062 \text{ m}^3/\text{kg} /(862 \text{ m/s}) = \mathbf{0.01283 \text{ m}^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.78

Steam at 800 kPa, 350°C flows through a convergent-divergent nozzle that has a throat area of 350 mm^2. The pressure at the exit plane is 150 kPa and the exit velocity is 800 m/s. The flow from the nozzle entrance to the throat is reversible and adiabatic. Determine the exit area of the nozzle, the overall nozzle efficiency, and the entropy generation in the process.

$h_{o1} = 3161.7$ kJ/kg, $s_{o1} = 7.4089$ kJ/kg K

$P^*/P_{o1} = (2/(k+1))^{k/(k-1)} = 0.54099 \Rightarrow P^* = 432.7$ kPa

At *: $(P^*, s^* = s_{o1}) \Rightarrow h^* = 2999.3$ kJ/kg, $v^* = 0.5687$ m^3/kg

$\Delta h = \mathbf{V}^2/2 \Rightarrow \mathbf{V}^* = \sqrt{2000(3161.7-2999.3)} = 569.9$ m/s

$\dot{m} = A\mathbf{V}^*/v^* = 350 \times 10^{-6} \times 569.9/0.5687 = 0.3507$ kg/s

$h_e = h_{o1} - \mathbf{V}_e^2/2 = 3161.7 - 800^2/2 \times 1000 = 2841.7$ kJ/kg

Exit: P_e, h_e: $v_e = 1.395$ m^3/kg, $s_e = 7.576$ kJ/kg K

$A_e = \dot{m} v_e/\mathbf{V}_e = 0.3507 \times 1.395/800 =$ **6.115×10^{-4} m^2**

$s_{gen} = s_e - s_{o1} = 7.576 - 7.4089 =$ **0.167 kJ/kg K**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.79

A convergent nozzle with exit diameter of 2 cm has an air inlet flow of 20°C, 101 kPa (stagnation conditions). The nozzle has an isentropic efficiency of 95% and the pressure drop is measured to 50 cm water column. Find the mass flow rate assuming compressible adiabatic flow. Repeat calculation for incompressible flow.

Convert ΔP to kPa:

$\Delta P = 50 \text{ cm } H_2O = 0.5 \times 9.8064 = 4.903 \text{ kPa}$

$T_0 = 20°C = 293.15 \text{ K} \qquad P_0 = 101 \text{ kPa}$

Assume inlet $V_i = 0 \qquad P_e = P_0 - \Delta P = 101 - 4.903 = 96.097 \text{ kPa}$

$$T_e = T_0 \left(\frac{P_e}{P_0}\right)^{\frac{k-1}{k}} = 293.15 \times \left(\frac{96.097}{101}\right)^{0.2857} = 289.01$$

$$\mathbf{V}_e^2/2 = h_i - h_e = C_p (T_i - T_e) = 1.004 \times (293.15 - 289.01)$$

$$= 4.1545 \text{ kJ/kg} = 4254.5 \text{ J/kg} \quad \Rightarrow \quad \mathbf{V}_e = 91.15 \text{ m/s}$$

$$\mathbf{V}_{e\,ac}^{\,2}/2 = \eta\, \mathbf{V}_{e\,s}^{\,2}/2 = 0.95 \times 4154.5 = 3946.78 \quad \Rightarrow \quad \mathbf{V}_{e\,ac} = 88.85 \text{ m/s}$$

$$T_{e\,ac} = T_i - \frac{V_{e\,ac}^{\,2}/2}{C_p} = 293.15 - \frac{3.9468}{1.0035} = 289.2 \text{ K}$$

$$\rho_{e\,ac} = \frac{P_e}{RT_p} = \frac{96.097}{0.287 \times 289.2} = 1.158 \text{ kg/m}^3$$

$$\dot{m} = \rho A \mathbf{V} = 1.158 \text{ kg/m}^3 \times \frac{\pi}{4} \times 0.02^2 \text{ m}^2 \times 88.85 \text{ m/s} = \mathbf{0.0323 \text{ kg/s}}$$

For incompressible flow:

$$\mathbf{V}_e^2/2 = (P_i - P_e)v = (P_i - P_e)\frac{RT_i}{P_i} = 4.903 \text{ kPa} \times \frac{0.287 \text{ kJ/kg-K } 293.15 \text{ K}}{101 \text{ kPa}}$$

$$= 4.903 \times 0.833 \text{ kJ/kg} = 4.084 \text{ kJ/kg} = 4084 \text{ J/kg}$$

$$\mathbf{V}_{e\,ac}^{\,2}/2 = \eta\, \mathbf{V}_{e\,s}^{\,2}/2 = 0.95 \times 4084 = 3880 \text{ J/kg} \quad \Rightarrow \quad \mathbf{V}_{e\,ac} = 88.09 \text{ m/s}$$

$$\dot{m} = \rho A \mathbf{V} = (1/0.833) \text{ kg/m}^3 \times \frac{\pi}{4} \times 0.02^2 \text{ m}^2 \times 88.09 \text{ m/s} = \mathbf{0.0332 \text{ kg/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.80

The coefficient of discharge of a sharp-edged orifice is determined at one set of conditions by use of an accurately calibrated gasometer. The orifice has a diameter of 20 mm and the pipe diameter is 50 mm. The absolute upstream pressure is 200 kPa and the pressure drop across the orifice is 82 mm of mercury. The temperature of the air entering the orifice is 25°C and the mass flow rate measured with the gasometer is 2.4 kg/min. What is the coefficient of discharge of the orifice at these conditions?

$\Delta P = 82 \times 101.325/760 = 10.93$ kPa

$\Delta T = T_i \left(\frac{k-1}{k}\right) \Delta P/P_i = 298.15 \times \frac{0.4}{1.4} \times 10.93/200 = 4.66$

$v_i = RT_i/P_i = 0.4278$ m^3/kg, $\quad v_e = RT_e/P_e = 0.4455$ m^3/kg

$\mathbf{V}_i = \mathbf{V}_e A_e v_i / A_i v_e = 0.1536\, \mathbf{V}_e$

$(\mathbf{V}_e^2 - \mathbf{V}_i^2)/2 = \mathbf{V}_e^2 (1 - 0.1536^2)/2 = h_i - h_e = C_p \Delta T$

$\mathbf{V}_e = \sqrt{2 \times 1000 \times 1.004 \times 4.66/(1 - 0.1536^2)} = 97.9$ m/s

$\dot{m}_s = A_e \mathbf{V}_e / v_e = \frac{\pi}{4} \times 0.02^2 \times 97.9/0.4455 = 0.069$ kg/s

$C_D = \dot{m}_a / \dot{m}_s = 2.4/(60 \times 0.069) = \mathbf{0.58}$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.81

A convergent nozzle is used to measure the flow of air to an engine. The atmosphere is at 100 kPa, 25°C. The nozzle used has a minimum area of 2000 mm^2 and the coefficient of discharge is 0.95. A pressure difference across the nozzle is measured to 2.5 kPa. Find the mass flow rate assuming incompressible flow. Also find the mass flow rate assuming compressible adiabatic flow.

Assume $\mathbf{V}_i \cong 0$, $\quad v_i = RT_i/P_i = 0.287 \times 298.15/100 = 0.8557\ m^3/kg$

Incompressible flow:

$\mathbf{V}_{e,s}^{\ 2}/2 = h_i - h_{e,s} = v_i(P_i - P_e) = 2.1393\ kJ/kg$

$\mathbf{V}_{e,s} = \sqrt{2 \times 1000 \times 2.1393} = 65.41\ m/s$

$\dot{m}_s = A\mathbf{V}_{e,s}/v_i = 2000 \times 10^{-6} \times 65.41/0.8557 = 0.153\ kg/s$

$\dot{m}_a = C_D\dot{m}_s =$ **0.1454 kg/s**

Compressible flow:

$T_{e,s} = T_i\,(P_e/P_i)^{(k-1)/k} = 298.15(97.5/100)^{0.2857} = 296\ K$

$\Delta h = C_p\Delta T = 1.0035 \times 2.15 = 2.1575 = \mathbf{V}_{e,s}^{\ 2}/2$

$\mathbf{V}_{e,s} = \sqrt{2 \times 1000 \times 2.1575} = 65.69\ m/s$

$v_{e,s} = 0.287 \times 296/97.5 = 0.8713\ m^3/kg$

$\dot{m}_s = A\mathbf{V}_{e,s}/v_{e,s} = 2000 \times 10^{-6} \times 65.69/0.8713 = 0.1508\ kg/s$

$\dot{m}_a = C_D\dot{m}_s =$ **0.1433 kg/s**

15.82

Atmospheric air is at 20°C, 100 kPa with zero velocity. An adiabatic reversible compressor takes atmospheric air in through a pipe with cross-sectional area of 0.1 m^2 at a rate of 1 kg/s. It is compressed up to a measured stagnation pressure of 500 kPa and leaves through a pipe with cross-sectional area of 0.01 m^2. What are the required compressor work and the air velocity, static pressure, and temperature in the exit pipeline?

C.V. compressor out to standing air and exit to stagnation point.

$$\dot{m}\, h_{o1} + \dot{W}_c = \dot{m}(h + \mathbf{V}^2/2)_{ex} = \dot{m} h_{o,ex}$$

$$\dot{m} s_{o1} = \dot{m} s_{o,ex} \Rightarrow P_{r,o,ex} = P_{r,o1}$$

$$(P_{st,ex}/P_{o1}) = 1.028(500/100) = 5.14$$

$$\Rightarrow T_{o,ex} = 463 \text{ K}, \quad h_{o,ex} = 465.38 \text{ kJ/kg}, \quad h_{o1} = 209.45 \text{ kJ/kg}$$

$$\dot{W}_c = \dot{m}(h_{o,ex} - h_{o1}) = 1(465.38 - 209.45) = \mathbf{255.9\ kW}$$

$$P_{ex} = P_{o,ex}(T_{ex}/T_{o,ex})^{k/(k-1)} \qquad T_{ex} = T_{o,ex} - \mathbf{V}_{ex}^2/2C_p$$

$$\dot{m} = 1 \text{ kg/s} = (\rho A \mathbf{V})_{ex} = P_{ex} A V_{ex}/RT_{ex}$$

Now select 1 unknown amongst P_{ex}, T_{ex}, V_{ex} and write the continuity eq. $\dot{m}$ and solve the nonlinear equation. Say, use T_{ex} then

$$\mathbf{V}_{ex} = \sqrt{2C_p(T_{o,ex} - T_{ex})}$$

$$\dot{m} = 1 \text{ kg/s} = P_{o,ex}(T_{ex}/T_{o,ex})^{k/k-1} A \sqrt{2C_p(T_{o,ex} - T_{ex})}/RT_{ex}$$

solve for $T_{ex}/T_{o,ex}$ (close to 1)

$$T_{ex} = \mathbf{462.6\ K} \Rightarrow \mathbf{V}_{ex} = \mathbf{28.3\ m/s}, \quad P_{ex} = \mathbf{498.6\ kPa}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.83

The nozzle in Problem 15.46 will have a throat area of 0.001272 m^2 and an exit area 3.50 times as large. Suppose the back pressure is raised to 1.4 MPa and that the flow remains isentropic except for a normal shock wave. Verify that the shock mach number (M_x) is close to 2 and find the exit mach number, the temperature and the mass flow rate through the nozzle.

Since a shock is present we must have choked flow with $M^* = 1$, then the mass flow rate is maximum and follows Eq.15.42

$$\dot{m}/A^* = P_o \sqrt{k/RT_o} \times [\frac{k+1}{2}]^{-(k+1)/2(k-1)}$$

$$= 2000 \text{ kPa} \times 1000\sqrt{1.4/(0.287 \times 423.15 \times 1000)} \text{ m/s} \times 1.2^{-2.4/0.8}$$

$$= 3929.72 \text{ kg/sm}^2$$

$$\dot{m} = A^* \times 3929.72 \text{ kg/sm}^2 = \mathbf{5 \text{ kg/s}}$$

Assume $M_x = 2$ then

Table A.13: $M_y = 0.57735$, $P_{oy}/P_{ox} = 0.72087$, $A_E/A_x^* = 3.50$

From A.12, $M_x = 2$: $A_x/A_x^* = 1.6875$, (upstream),

$M_y = 0.57735$: $A_y/A_y^* = 1.2225$, (downstream)

Now since $A_y = A_x$ then (see Ex. 15.9 page 734)

$$A_E/A_y^* = [A_E/A_x^*]\,[A_y/A_y^*]\,[A_x^*/A_x] = 3.5 \times 1.2225/1.6875 = 2.5356$$

From A.12 with A/A^* then: $M_E = \mathbf{0.246}$, $P_E/P_{oy} = 0.95728$

$P_E = 0.95728 \times 0.72087 \times 2.0 = 1.38$ MPa, OK close to the 1.4 MPa

$T_E = 0.9876 \times 423.15 = \mathbf{418 \text{ K}}$,

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.84

At what Mach number will the normal shock occur in the nozzle of Problem 15.53 if the back pressure is 1.4 MPa? (trial and error on M_x)

Relate the inlet and exit conditions to the shock conditions with reversible flow before and after the shock. It becomes trial and error.

Assume $M_x = 1.8 \Rightarrow M_y = 0.6165$; $P_{oy}/P_{ox} = 0.8127$

$A_E/A^*_x = A_2/A^* = 0.002435/0.001516 = 1.6062$

$A_x/A^*_x = 1.439$; $A_x/A^*_y = 1.1694$

$$A_E/A^*_y = (A_E/A^*_x)(A_x/A^*_y)/(A_x/A^*_x) = \frac{1.6062(1.1694)}{1.439} = 1.3053$$

$\Rightarrow M_E = 0.5189$; $P_E/P_{oy} = 0.8323$

$P_E = (P_E/P_{oy})(P_{oy}/P_{ox})P_{ox} = 0.8323 \times 0.8127 \times 2000 = 1353$ kPa < 1.4 MPa

So select the mach number a little less

$M_x = 1.7 \Rightarrow M_y = 0.64055$; $P_{oy}/P_{ox} = 0.85573$

$A_x/A^*_x = 1.3376$; $A_x/A^*_y = 1.1446$

$$A_E/A^*_y = (A_E/A^*_x)(A_x/A^*_y)/(A_x/A^*_x) = \frac{1.6062(1.1446)}{1.3376} = 1.3744$$

$\Rightarrow M_E = 0.482$; $P_E/P_{oy} = 0.853$

$P_E = (P_E/P_{oy})(P_{oy}/P_{ox})P_{ox} = 0.853 \times 0.85573 \times 2000 = 1459.9$ kPa

Now interpolate between the two

$M_x =$ **1.756** and we check $\Rightarrow M_y = 0.6266$; $P_{oy}/P_{ox} = 0.832$

$A_x/A^*_x = 1.3926$; $A_x/A^*_y = 1.1586$

$A_E/A^*_y = 1.6062 \times 1.1586/1.3926 = 1.3363$

$\Rightarrow M_E = 0.5$; $P_E/P_{oy} = 0.843$

$P_E = 0.843 \times 0.832 \times 2000 = 1402.7$ kPa **OK**

Solution using the Pr or vr functions

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.44

A jet plane travels through the air with a speed of 1000 km/h at an altitude of 6 km, where the pressure is 40 kPa and the temperature is −12°C. Consider the inlet diffuser of the engine where air leaves with a velocity of 100 m/s. Determine the pressure and temperature leaving the diffuser, and the ratio of inlet to exit area of the diffuser, assuming the flow to be reversible and adiabatic.

$\mathbf{V}$ = 1000 km/h = 277.8 m/s, $v_1 = \frac{RT}{P} = \frac{0.287 \times 261.15}{40} = 1.874$ m^3/kg

$h_1 = 261.48$ kJ/kg, $P_{r1} = 0.6862$

$h_{o1} = 261.48 + 277.8^2/2000 = 300.07$ kJ/kg

$\Rightarrow T_{o1} = 299.7$ K, $P_{ro1} = 1.1107$

The ratio of the pressures equals the ratio of the Pr functions when s = constant

$P_{o1} = P\, P_{ro1}/ P_{r1} = 40 \times 1.1107/0.6862 = 64.74$ kPa

$h_2 = 300.07 - 100^2/2000 = 295.07 \quad \Rightarrow \quad T_2 =$ **294.7 K**, $P_{r2} = 1.0462$

$P_2 = 64.74 \times 1.0462/1.1107 =$ **61 kPa**

$v_2 = RT_2/P_2 = 0.287 \times 294.7/61 = 1.386$ m^3/kg

$A_1/A_2 = (v_1/v_2)(V_2/V_1) = (1.874/1.386)(100/277.8) =$ **0.487**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.73

Repeat Problem 15.44 assuming a diffuser efficiency of 80%.

$\mathbf{V}$ = 1000 km/h = 277.8 m/s, $v_1 = \frac{RT}{P} = \frac{0.287 \times 261.15}{40} = 1.874$ m^3/kg

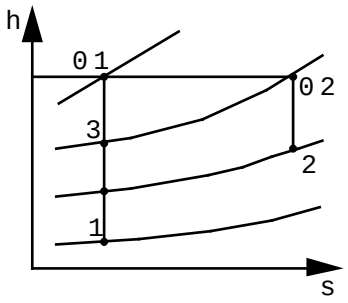
$h_1 = 261.48$ kJ/kg, $P_{r1} = 0.6862$

$h_{o1} = 261.48 + 277.8^2/2000 = 300.07$ kJ/kg

$\Rightarrow T_{o1} = 299.7$ K, $P_{ro1} = 1.1107$

Same as problem 15.44, except
$\eta_D = 0.80$. We thus have from 15.44

$$\frac{h_3 - h_1}{h_{o1} - h_1} = \frac{h_3 - 261.48}{300.07 - 261.48} = 0.8$$



$\Rightarrow h_3 = 292.35$ kJ/kg, $P_{r3} = 1.0129$

$P_{o2} = P_3 = 40 \times 1.0129/0.6862 = 59.04$ kPa

$P_{ro2} = P_{ro1} = 1.1107$

$h_2 = 300.07 - 100^2/2000 = 295.07$ kJ/kg $\Rightarrow T_2 =$ **294.7 K**, $P_{r2} = 1.0462$

$P_2 = P_{o2} P_{r2} / P_{ro2} = 59.04 \times 1.0462/1.1107 =$ **55.6 kPa**

$v_2 = RT_2/P_2 = 0.287 \times 294.7/55.6 = 1.521$ m^3/kg

$A_1/A_2 = (v_1/v_2)(V_2/V_1) = (1.874/1.521)\ (100/277.8) =$ **0.444**

CHAPTER 15

CONTENT CHAPTER 15

SUBSECTION	PROB NO.
Stagnation properties	85-87
Momentum Equation and Forces	88-89
Velocity of Sound	90
Reversible Flow Through a Nozzle	91-99
Normal Shocks	100
Nozzles, Diffusers and Orifices	101-103

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Stagnation properties

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.85E

Steam leaves a nozzle with a velocity of 800 ft/s. The stagnation pressure is 100 lbf/in^2, and the stagnation temperature is 500 F. What is the static pressure and temperature?

$$h_1 = h_{o1} - \mathbf{V}_1^2/2 = 1279.1 - \frac{800^2}{2 \times 32.174 \times 778} = 1266.3 \frac{\text{Btu}}{\text{lbm}}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 (= 32.174 × 778.1693)

Assume isentropic flow

$s_1 = s_0 = 1.7085$ Btu/lbm R

(h, s) Computer table $\Rightarrow$ P_1 = **88 lbf/in.^{2}**, T = **466 F**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.86E

Air leaves the compressor of a jet engine at a temperature of 300 F, a pressure of 45 lbf/in^2, and a velocity of 400 ft/s. Determine the isentropic stagnation temperature and pressure.

$$h_{o1} - h_1 = \mathbf{V}_1^2/2 = 400^2/(2 \times 32.174 \times 778) = 3.2 \text{ Btu/lbm}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 (= 32.174 × 778.1693)

$$T_{o1} - T - 1 = (h_{o1} - h_1)/C_p = 3.2/0.24 = 13.3$$

$$T_{o1} = T + \Delta T = 300 + 13.3 = 313.3 \text{ F} = \mathbf{773\ R}$$

$$P_{o1} = P_1 \left(T_{o1}/T_1\right)^{\frac{k}{k-1}} = 45(773/759.67)^{3.5} = \mathbf{47.82\ lbf/in^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.87E

A meteorite melts and burn up at temperatures of 5400 R. If it hits air at 0.75 lbf/in.^{2}, 90 R how high a velocity should it have to reach such temperature?

Assume we have a stagnation T = 5400 R

$h_1 + \mathbf{V}_1^2/2 = h_{stagn.}$

Extrapolating from table F.5, $h_{stagn.} = 1515.6$, $h_1 = 21.4$ Btu/lbm

$\mathbf{V}_1^2/2 = 1515.6 - 21.4 = 1494.2$ Btu/lbm

$\mathbf{V}_1 = \sqrt{2 \times 32.174 \times 778 \times 1494.2}$ = **8649 ft/s**

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 (= 32.174 × 778.1693)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Momentum Equation and Forces

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.88E

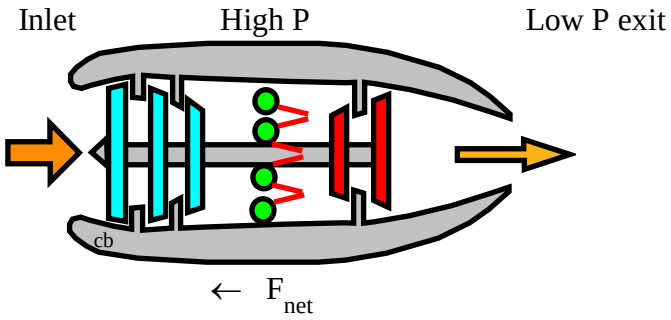
A jet engine receives a flow of 500 ft/s air at 10 lbf/in.^{2}, 40 F inlet area of 7 ft^2 with an exit at 1500 ft/s, 10 lbf/in.^{2}, 1400 R. Find the mass flow rate and thrust.

$\dot{m} = \rho A \mathbf{V}$; ideal gas $\rho = P/RT$

$$\dot{m} = (P/RT)A\,\mathbf{V} = \frac{10 \text{ psi} \times 144 \text{ in}^2/\text{ft}^2}{53.34 \text{ lbf-ft/lbm-R} \times 499.7 \text{ R}} \times 7 \text{ ft}^2 \times 500 \text{ ft/s}$$

$$= 189.1 \text{ lbm/s}$$

$$F_{net} = \dot{m}(\mathbf{V}_{ex} - \mathbf{V}_{in}) = \frac{189.1 \text{ lbm/s} \times (1500 - 500) \text{ ft/s}}{32.174 \text{ lbm-ft/s}^2\text{-lbf}} = \mathbf{5877 \text{ lbf}}$$



The shaft must have axial load bearings to transmit thrust to aircraft.

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.89E

A water turbine using nozzles is located at the bottom of Hoover Dam 575 ft below the surface of Lake Mead. The water enters the nozzles at a stagnation pressure corresponding to the column of water above it minus 20% due to friction. The temperature is 60 F and the water leaves at standard atmospheric pressure. If the flow through the nozzle is reversible and adiabatic, determine the velocity and kinetic energy per kilogram of water leaving the nozzle.

$$\Delta P = \rho\, g\Delta Z = g(\Delta Z/v) = \frac{32.174 \times 575}{0.016035 \times 144 \times 32.174} = 249 \text{ lbf/in.}^2$$

$$\Delta P_{ac} = 0.8\Delta P = 199.2 \text{ lbf/in.}^2 \quad \text{and Bernoulli} \quad v\Delta P = \mathbf{V}_{ex}^{\,2}/2$$

$$\mathbf{V}_{ex} = \sqrt{2v\Delta P} = \sqrt{2g\Delta Z} = \sqrt{2 \times 32.174 \text{ ft/s}^2 \times 575 \text{ ft}} = \mathbf{192.4 \text{ ft/s}}$$

$$\mathbf{V}_{ex}^{\,2}/2 = v\Delta P = g\Delta Z = 575/778 = \mathbf{0.739 \text{ Btu/lbm}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Velocity of Sound

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.90E

Find the speed of sound for air at 15 lbf/in.^{2}, at the two temperatures of 32 F and 90 F. Repeat the answer for carbon dioxide and argon gases.

We assume all gases can be treated as ideal gas behavior

From eq. 15.28 we have

$$c_{32} = \sqrt{kRT} = \sqrt{1.4 \times 32.174 \text{ lbm-ft/s}^2\text{-lbf} \times 53.34 \text{ lbf-ft/lbm-R} \times 491.7 \text{ R}}$$

$$= \mathbf{1087 \text{ ft/s}}$$

$$c_{90} = \sqrt{1.4 \times 32.174 \times 53.34 \times 549.7} = \mathbf{1149 \text{ ft/s}}$$

For Carbon Dioxide: R = 35.1 lbf-ft/lbm-R, k = 1.289

$$c_{32} = \sqrt{1.289 \times 32.174 \times 35.1 \times 491.7} = \mathbf{846 \text{ ft/s}}$$

$$c_{90} = \sqrt{1.289 \times 32.174 \times 35.1 \times 549.7} = \mathbf{894.5 \text{ ft/s}}$$

For Argon: R = 38.68 lbf-ft/lbm-R, k = 1.667

$$c_{32} = \sqrt{1.667 \times 32.174 \times 38.68 \times 491.7} = \mathbf{1010 \text{ ft/s}}$$

$$c_{90} = \sqrt{1.667 \times 32.174 \times 38.68 \times 549.7} = \mathbf{1068 \text{ ft/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.91E

A jet flies at an altitude of 40 000 ft where the air is at -40 F, 6.5 psia with a velocity of 625 mi/h. Find the Mach number and the stagnation temperature on the nose.

From Table F.4: $k = C_p/C_v = 1.4$; $R = 53.34$ ft-lbf/lbm-R

Now do the speed of sound from Eq.15.28

$$c = \sqrt{kRT} = \sqrt{1.4 \times 32.174 \text{ lbm-ft/s}^2\text{-lbf} \times 53.34 \text{ lbf-ft/lbm-R} \times 419.7 \text{ R}}$$
$$= 1004 \text{ ft/s}$$

$\mathbf{V} = 625$ mi/h $= 625$ (mi/h) $\times$ 1.46667 (ft/s) / (mi/h) $= 917$ ft/s

$M = \mathbf{V} / c = 917/1004 =$ **0.913**

$h_0 = h_1 + \mathbf{V}_1^2/2$ ⇨

$$T_0 = T_1 + \mathbf{V}_1^2 / 2C_p = -40 + \frac{917^2}{2 \times 0.24 \times 25037} = \mathbf{29.97\ F}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 (= 32.174 × 778.1693)

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

Flow Through Nozzles, Shocks

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.92E

Steam flowing at 50 ft/s 200 psia, 600 F expands to 150 psia in a converging nozzle. Find the exit velocity and area ratio A_e / A_i.

Solve the problem with the steam tables.

Inlet state: $v_i = 3.058$ ft^3/lbm, $h_i = 1322.05$ Btu/lbm, $s_i = 1.6767$ Btu/lbm-R

Exit state: (P_e,$s_e = s_i$) $v_e = 3.8185$ ft^3/lbm, $h_e = 1290.69$ Btu/lbm

Energy Eq.: $\mathbf{V}_i^2 / 2 + h_i = \mathbf{V}_e^2 / 2 + h_e$; $\mathbf{V}_e^2 = \mathbf{V}_i^2 + 2(h_i - h_e)$

$$\mathbf{V}_e = \sqrt{50 \times 50 + 2 \times 25037 \times (1322.05 - 1290.69)} = \mathbf{1254\ ft/s}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 (= 32.174 × 778.1693)

Same mass flow rate so

$$A_e/A_i = (v_e/v_i)(V_i/V_e) = \frac{3.8185}{3.058} \times \frac{50}{1254} = \mathbf{0.0498}$$

If we solved as ideal gas with constant specific heat we get (k = 1.327)

$$T_e = T_i\,(P_e/P_i)^{(k-1)/k} = 1059.7\,(150/200)^{0.2464} = 987.2\ R$$

$$\mathbf{V}_e = \sqrt{\mathbf{V}_i^2 + 2C_p(T_i - T_e)} = \sqrt{50 \times 50 + 2 \times 0.447 \times 25037(1059.7 - 987.2)}$$
$$= 1274.9\ ft/s$$

$$A_e/A_i = (v_e/v_i)(V_i/V_e) = (P_i/P_e)^{1/k}(V_i/V_e) = \left(\frac{200}{150}\right)^{0.7536} \times \frac{50}{1274.9}$$
$$= \mathbf{0.0487}$$

15.94E

A jet plane travels through the air with a speed of 600 mi/h at an altitude of 20000 ft, where the pressure is 5.75 lbf/in.^{2} and the temperature is 25 F. Consider the diffuser of the engine where air leaves at with a velocity of 300 ft/s. Determine the pressure and temperature leaving the diffuser, and the ratio of inlet to exit area of the diffuser, assuming the flow to be reversible and adiabatic.

V = 600 mi/h = 880 ft/s

$v_1 = 53.34 \times 484.67/(5.75 \times 144) = 31.223$ ft^3/lbm,

$h_1 = 115.91$ Btu/lbm,

$h_{o1} = 115.91 + 880^2/(2 \times 25\ 037) = 131.38$ Btu/lbm

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 (= 32.174 × 778.1693)

Table F.5 $\Rightarrow$ $T_{o1} = 549.2$ R,

$$P_{o1} = P_1 (T_{o1}/T_1)^{k/(k-1)} = 5.75 \times (549.2/484.67)^{3.5} = 8.9 \text{ lbf/in.}^2$$

$h_2 = 131.38 - 300^2/(2 \times 32.174 \times 778) = 129.58$ Btu/lbm

$T_2 =$ **542 R**, =>

$P_2 = P_{o1} (T_2/T_{o1})^{k/(k-1)} = 8.9 \times (542/549.2)^{3.5} =$ **8.5 lbf/in.^{2}**

$v_2 = 53.34 \times 542/(8.5 \times 144) = 23.62$ ft^3/lbm

$A_1/A_2 = (v_1/v_2)(V_2/V_1) = (31.223/23.62)(300/880) =$ **0.45**

15.95E

An air flow at 90 psia, 1100 R, $M = 0.3$ flows into a convergent-divergent nozzle with $M = 1$ at the throat. Assume a reversible flow with an exit area twice the throat area and find the exit pressure and temperature for subsonic exit flow to exist.

To find these properties we need the stagnation properties from the inlet state

From Table A.12: $M_i = 0.3$: $P_i/P_o = 0.93947$, $T_i/T_o = 0.98232$

$P_o = 90 / 0.93947 = 95.8$ psia, $T_o = 1100 / 0.98232 = 1119.8$ R

This flow is case c in Figure 15.13. From Table A.12: $A_E/A^* = 2$

$P_E/P_o = 0.9360$, $T_E/T_o = 0.98127$

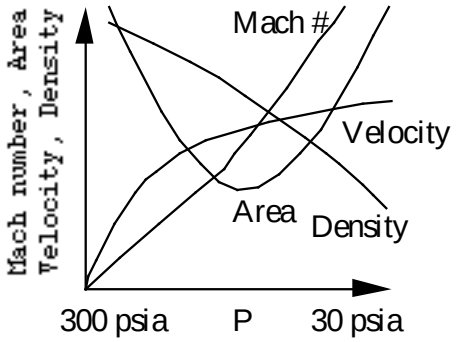
$P_E = 0.9360\ P_o = 0.936 \times 95.8 =$ **89.67 psia**

$T_E = 0.98127\ T_o = 0.98127 \times 1119.8 =$ **1099 R**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.96E

Air is expanded in a nozzle from 300 lbf/in.2, 1100 R to 30 lbf/in.^{2}. The mass flow rate through the nozzle is 10 lbm/s. Assume the flow is reversible and adiabatic and determine the throat and exit areas for the nozzle.



$$P^* = P_o \left(\frac{2}{k+1}\right)^{\frac{k}{k-1}}$$

$$= 300 \times 0.5283 = 158.5 \text{ lbf/in.}^2.$$

$$T^* = T_o \times 2/(k+1) = 1100 \times 0.8333 = 916.6 \text{ R}$$

$$v^* = RT^*/P^* = 53.34 \times 916.6/(158.5 \times 144)$$

$$= 2.1421 \text{ ft}^3/\text{lbm}$$

The critical speed of sound is

$$c^* = \sqrt{kRT^*} = \sqrt{1.4 \times 32.174 \times 53.34 \times 916.6} = 1484 \text{ ft/s}$$

$$A^* = \dot{m}v^*/c^* = 10 \times 2.1421/1484 = \mathbf{0.0144\ ft^2}$$

$$P_2/P_o = 30/300 = 0.1 \quad \text{Table A.11} \Rightarrow \quad M_2^* = 1.701 = \mathbf{V}_2/c^*$$

We used the column in Table A.12 with mach no. based on throat speed of sound.

$$\mathbf{V}_2 = 1.701 \times 1484 = 2524 \text{ ft/s}$$

$$T_2 = 916.6 \times 0.5176 = 474.4 \text{ R}$$

$$v_2 = RT_2/P_2 = 53.34 \times 474.4/(30 \times 144) = 5.8579 \text{ ft}^3/\text{lbm}$$

$$A_2 = \dot{m}v_2/\mathbf{V}_2 = 10 \times 5.8579 / 2524 = \mathbf{0.0232\ ft^2}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

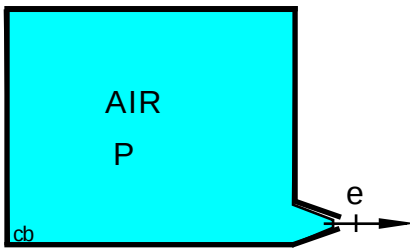
15.97E

A 50-ft^3 uninsulated tank contains air at 150 lbf/in.^{2}, 1000 R. The tank is now discharged through a small convergent nozzle to the atmosphere at 14.7 lbf/in.^{2} while heat transfer from some source keeps the air temperature in the tank at 1000 R. The nozzle has an exit area of 2×10^{-4} ft^2.

a. Find the initial mass flow rate out of the tank.

b. Find the mass flow rate when half the mass has been discharged.

c. Find the mass of air in the tank and the mass flow rate out of the tank when the nozzle flow changes to become subsonic.



$P_B/P_o = 14.7/150 = 0.098 \; < \; (P^*/P_o)_{crit} = 0.5283$

a. The flow is choked, max possible flow rate

$M_E = 1$; $P_E = 0.5283 \times 150 = 79.245$ lbf/in.^{2}

$T_E = T^* = 0.8333 \times 1000 = 833.3$ R

$\mathbf{V}_E = c = \sqrt{kRT^*} = \sqrt{1.4 \times 53.34 \times 833.3 \times 32.174} = 1415$ ft/s

$v_E = RT^*/P_E = 53.34 \times 833.3/(79.245 \times 144) = 3.895$ ft^3/lbm

Mass flow rate is : $\dot{m}_1 = A\mathbf{V}_E/v_E = 2 \times 10^{-4} \times 1415/3.895 =$ **0.0727 lbm/s**

b. $m_1 = P_1V/RT_1 = 150 \times 50 \times 144/53.34 \times 1000 = 20.247$ lbm

$m_2 = m_1/2 = 10.124$ lbm, $P_2 = P_1/2 = 75$ lbf/in.^{2} ; $T_2 = T_1$

$P_B/P_2 = 14.7/75 = 0.196 \; < \; (P^*/P_o)_{crit}$

The flow is choked and the velocity is the same as in a)

$P_E = 0.5283 \times 75 = 39.623$ lbf/in.^{2} ; $M_E = 1$

$$\dot{m}_2 = A\mathbf{V}_E P_E/RT_E = \frac{2 \times 10^{-4} \times 1415 \times 39.623 \times 144}{53.34 \times 1000} = \mathbf{0.0303 \text{ lbm/s}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

c. Flow changes to subsonic when the pressure ratio reaches critical.

$P_B/P_o = 0.5283$ $P_3 = 27.825$ lbf/in.^{2}

$m_3 = m_1 P_3/P_1 =$ **3.756 lbm** ; $T_3 = T_1 \Rightarrow \mathbf{V}_E = 1415$ ft/s

$$\dot{m}_3 = A\mathbf{V}_E P_E/RT_E = \frac{2 \times 10^{-4} \times 1415 \times 27.825 \times 144}{53.34 \times 1000} = \mathbf{0.02125\ lbm/s}$$

15.98E

A flow of helium flows at 75 psia, 900 R with 330 ft/s into a convergent-divergent nozzle. Find the throat pressure and temperature for reversible flow and $M = 1$ at the throat.

We need to find the stagnation properties first (k = 1.667)

$$T_0 = T_1 + \mathbf{V}_1^2/2C_p = 900 + 330^2/(2 \times 25037 \times 1.24) = 901.754 \text{ R}$$

Recall conversion 1 Btu/lbm = 25 037 ft^2/s^2 (= 32.174 × 778.1693)

$$P_0 = P_1 (T_0/T_1)^{k/(k-1)} = 75 (901.754/900)^{2.5} = 75.366 \text{ psia}$$

From the analysis we get Eqs.15.37-38

$$P^* = P_0 \left(\frac{2}{k+1}\right)^{k/(k-1)} = 75.366 \left(\frac{2}{1.667+1}\right)^{2.5} = \mathbf{36.7 \text{ psia}}$$

$$T^* = T_0 \frac{2}{k+1} = 901.754 \times \frac{2}{1.667+1} = \mathbf{676.2 \text{ R}}$$

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.99E

The products of combustion enter a nozzle of a jet engine at a total pressure of 18 lbf/in.^{2}, and a total temperature of 1200 F. The atmospheric pressure is 6.75 lbf/in.^{2}. The nozzle is convergent, and the mass flow rate is 50 lbm/s. Assume the flow is adiabatic. Determine the exit area of the nozzle.

$P_{crit} = P_2 = 18 \times 0.5283 = 9.5$ lbf/in.^{2} > P_{amb}

The flow is then choked.

$T_2 = 1660 \times 0.8333 = 1382$ R

$\mathbf{V}_2 = c_2 = \sqrt{kRT} = \sqrt{1.4 \times 32.174 \times 53.34 \times 1382} = 1822$ ft/s

$v_2 = 53.34 \times 1382/9.5 \times 144 = 53.9$ ft^3/lbm

$A_2 = \dot{m}\, v_2 / \mathbf{V}_2 = 50 \times 53.9/1822 =$ **1.479 ft^2**

Excerpts from this work may be reproduced by instructors for distribution on a not-for-profit basis for testing or instructional purposes only to students enrolled in courses for which this textbook has been adopted. *Any other reproduction or translation of this work beyond that permitted by Sections 107 or 108 of the 1976 United States Copyright Act without the permission of the copyright owner is unlawful.*

15.100E

A normal shock in air has upstream total pressure of 75 psia, stagnation temperature of 900 R and M_x = 1.4. Find the downstream stagnation pressure.

From the normal shock relations in Section 15.8 found in Table A.13 we get

M_x = 1.4: $\quad P_{oy}/P_{ox} = 0.95819$

$P_{oy} = 0.95819\ P_{ox} = 0.95819 \times 75 =$ **71.86 psi**

Remark: The stagnation temperature would be unchanged (energy equation).
